

Preface to the Application

The British Columbia (B.C.) Ministry of Transportation and Infrastructure (Ministry) is proposing the George Massey Tunnel Replacement Project (Project) to meet regional, provincial, and national transportation management goals. The Project involves replacement of the George Massey Tunnel (Tunnel) crossing of the Fraser River with a new bridge and replacement of three interchanges. The new bridge will be built at the same location as the Tunnel, which will be decommissioned once the bridge is open to traffic. The new bridge includes multi-use pathways for pedestrian and cycling traffic, which will connect to cycling and pedestrian networks in Richmond and Delta. The Project also includes related minor improvements to the Highway 99 corridor to support efficient use of the new crossing and interchanges, including provision of transit/high-occupancy vehicle (HOV) lanes and transit exchanges.

An environmental assessment of the Project is required under the B.C. *Environmental Assessment Act* (B.C. *EAA*), S.B.C. 2002, c. 43, and permits to construct and operate the Project can only be received once the environmental assessment process is complete and an Environmental Assessment Certificate (EAC) has been issued. If the Project is approved, an EAC will be awarded to and held by the Ministry. The Reviewable Projects Regulation B.C. Reg. 370/2002 under the B.C. *EAA* sets out the criteria for reviewable projects. The section of the regulation that applies to the Project is:

- Part 5 (Water Management Projects): The Tunnel decommissioning may result in a change in and about the Fraser River, and in direct physical disturbance of more than two hectares (ha) of foreshore and submerged land (*Reviewable Projects Regulation*, Part 5, Table 9, Shoreline Modification).
- Part 8 (Transportation Projects): Upgrades to Highway 99 and related interchanges involves the modification of an existing public highway that results in the addition of equal to or greater than two lanes of paved public highway to an existing paved public highway over a continuous distance of equal to or greater than 20 kilometres (*Reviewable Projects Regulation*, Part 5, Table 14, Transportation Projects).

On December 16, 2015, the B.C. Environmental Assessment Office (EAO) issued a section 10(1)(c) Order confirming that the Project is a reviewable project pursuant to the B.C. *EAA*, and that it requires an EAC.

The Project as proposed is not subject to review under the *Canadian Environmental Assessment Act, 2012*, S.C. 2012, c. 19, s. 52, since it does not meet the definition of a physical activity under the Schedule of Physical Activities in the Regulations Designating Physical Activities SOR/2012-147.

The Application for an EAC (Application), pursuant to the B.C. *EAA*, has been prepared in accordance with the Application Information Requirements approved by the EAO on May 24th, 2016, and complies with relevant instructions provided in the section 11 Order issued by the EAO on March 7th, 2016, pursuant to the B.C. *EAA*.

| | | enhancement of the environment in addition to avoiding or minimizing Project-related effects. | | |
| Section 3.6 Page 16 | Characterization of Residual Effects | Where residual effects are expected to persist after implementation of mitigation measures, such effects will be characterized for the relevant VC using the criteria listed below. The generalized criteria definitions presented in the list below will be used as a guide for establishing VC-specific effects characterization criteria, which will be described in the relevant effects assessment section of the Application. <ul style="list-style-type: none"> Direction (the overall nature of the residual effect): the direction of Project effects will be identified as positive (i.e., beneficial), neutral, or negative (i.e., adverse). | Characterization of Residual Effects | Part B – Effects, Section 3.6, pages 3.6-14 to 3.9-15 |
| | | <ul style="list-style-type: none"> Magnitude (the amount of change to the existing condition of a VC): magnitude will generally be measured in terms of the proportion of the VC that is affected relative to the range of natural variation (or historic variation, in the case of human environment VCs). | Characterization of Residual Effects | Part B – Effects, Section 3.6, page 3.6-14 |
| | | <ul style="list-style-type: none"> Geographic extent (the area over which Project-related changes would occur): geographic extent of effects will generally be described as site-specific (limited to the Project Area, – i.e. project footprint plus project disturbance area), local (limited to the LAA), regional (limited to the RAA), or beyond. | Characterization of Residual Effects | Part B – Effects, Section 3.6, page 3.6-14 |
| | | <ul style="list-style-type: none"> Duration (period of time for a VC to return to its existing condition): the duration of an effect will typically be described as short-term, long-term, or permanent; definitions of short- and long-term would vary by VC, and take into account VC-specific temporal characteristics. | Characterization of Residual Effects | Part B – Effects, Section 3.6, page 3.6-14 |
| | | <ul style="list-style-type: none"> Frequency (the number of times an effect might occur within a specific time period): the frequency of an effect may be described as continuous, frequent, uncommon, or rare. | Characterization of Residual Effects | Part B – Effects, Section 3.6, page 3.6-14 |
| | | <ul style="list-style-type: none"> Reversibility (degree to which existing conditions can be regained after the factors causing the effect are removed): effects will be described as reversible, permanent, or partially reversible. | Characterization of Residual Effects | Part B – Effects, Section 3.6, page 3.6-14 |
| | | Residual effects will be discussed in the context of the VC's current and future sensitivity and its resilience to change caused by the Project. Consideration of context will be based on the description of existing conditions of the VC, which reflect cumulative effects of other projects, and activities that have been carried out, and especially information about the impact of natural and human-caused trends in the condition of the VC. | Characterization of Residual Effects | Part B – Effects, Section 3.6, page 3.6-14 |
| | | The Application will describe, in a table format, the residual effects using the residual effects criteria context, magnitude, extent, duration, reversibility, and frequency, as defined in EAO's Guideline for the Selection of Valued Components and Assessment of Potential Effects. Where feasible, these criteria will be described quantitatively in the Application for each VC. When residual effects cannot be characterized quantitatively, the Application will characterize these effects qualitatively. Definitions will be provided when qualitative terms are used. | Characterization of Residual Effects | Part B – Effects, Section 3.6, pages 3.6-14 to 3.9-15 |
| | | The use of any qualitative terms (e.g. high, moderate, low, etc.) will be accompanied by distinct definitions for each of these rankings. An explanation will be included for the conclusion reached for each criterion used to characterize a residual effect. | Characterization of Residual Effects | Part B – Effects, Section 3.6, page 3.9-15 |
| | | When residual effects on a VC are determined and the VC is also considered a “pathway” for other potential effects on other VCs, the Application will identify the linkages between the VCs and the discipline-specific studies to which the information has been forwarded for further evaluation. | Characterization of Residual Effects | Part B – Effects, Section 3.6, page 3.9-15 |

| Section 3.7 Page 17 | Likelihood | The Application will assess the likelihood for all residual adverse effects using appropriate quantitative or qualitative terms and provide sufficient detail to help understand how the conclusions were reached. Definitions of any qualitative terms, such as 'low', 'moderate', or 'high' probability will be provided. | Likelihood | Part B – Effects, Section 3.7, page 3.9-15 |
| Section 3.8 Page 17 | Proponent's Determination of Significance | The Application will present the process and methodology used to define and evaluate the significance of residual effects, including how the term "significance" has been used in relation to each VC using quantitative and qualitative thresholds. | Proponent's Determination of Significance | Part B – Effects, Section 3.8, page 3.9-15 |
| | | A conclusion of significance of residual adverse effects will be provided for each VC. | Proponent's Determination of Significance | Part B – Effects, Section 3.8, page 3.9-15 |
| Section 3.9 Page 17 | Confidence and Risk | The Application will summarize the process and methodology used to evaluate the levels of confidence associated with residual effects predictions, and in particular, how any identified uncertainty may affect either the likelihood or the significance of the predicted residual effect. The Application will also describe any measures to reduce uncertainty through monitoring, adaptive management, or other follow-up programs. | Confidence and Risk | Part B – Effects, Section 3.9, Page 3.9-15 to 3.10-16 |
| | | The Application will summarize the process and methodology used to determine if additional risk analysis is required. If additional risk analysis is required, the Application will summarize the process and methodology used for this analysis and the conclusions, including the range of likely, plausible and possible outcomes with respect to likelihood and significance. | Confidence and Risk | Part B – Effects, Section 3.9, Page 3.9-15 to 3.10-16 |
| Section 3.10.1 Page 18 | Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities | The Application will use the steps outlined in Figure 3.10-1 Steps to Determine Residual Project and Cumulative Effects of the Application to determine residual Project effects and the subsequent cumulative effects assessment. | Cumulative Effects Assessment | Part B – Effects, Section 3.10, page 3.10-16 to 3.10-17 |
| | | The following development categories will be considered in the Application: <ul style="list-style-type: none"> ▫ Projects or activities that have already been built or conducted for which the environmental effects overlap with those of the proposed Project (i.e. certain): maintenance dredging of the lower Fraser River; Tilbury Liquefied Natural Gas (LNG) Facility Expansion Project; Port of Vancouver Habitat Enhancement Program; and Vancouver Airport Fuel Delivery Project. ▫ Projects that are either proposed (public disclosure) or have been approved to be built, but are not yet built, for which the environmental effects overlap the proposed Project (i.e. reasonably foreseeable), as identified in the AIR: Fraser Surrey Docks Direct Transfer Coal Facility (Texada Coal); WesPac Tilbury Marine Jetty Project; Pattullo Bridge Replacement; Roberts Bank Terminal 2 Project; Ladner Harbour Revitalization; South Richmond Terminal Project; Kinder Morgan Tran Mountain Pipeline Expansion Project; Relocation of BC Hydro's transmission line that runs through the Tunnel; Fortis BC Tilbury LNG Facility Expansion Project – future phase; and Lehigh Hanson South Richmond Terminal Project. | Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities | Part B – Effects, Section 3.10.1, pages 3.10-17 to 3.10-22 |
| | | The Application will describe the methodology for identifying potential interactions between residual Project effects and the effects of other developments, including a description of the following: <ul style="list-style-type: none"> ▫ The spatial boundaries for the cumulative effects assessment for each VC, including maps; ▫ The spatial and temporal boundaries of other developments; and ▫ The potential for interaction (spatial and temporal) and linkages (overlap) of VCs with other developments. | Conducting a Cumulative Effects Assessment | Part B – Effects, Section 3.10.2, pages 3.10-22 to 3.11-23 |
| | | The Application will include: <ul style="list-style-type: none"> ▫ A table of all past, present and reasonably foreseeable developments that will be included in the cumulative effects assessment, should one be required for a particular VC; ▫ A general description of the information sources used to identify reasonably foreseeable developments and activities; and ▫ A map showing the location of the projects and activities. | Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities | Part B – Effects, Section 3.10.1, page 3.10-17 and 3.10-22 |

| | | The following general approach has been adopted for collection of baseline information on river hydraulics and river morphology: <ul style="list-style-type: none"> • Review of existing field, modelling, and theoretical studies. This includes observed water levels (at Point Atkinson, New Westminster, Steveston, Deas Island Tunnel and Port Mann Pumping Station), and discharge, flow split, and velocity measurements from the March 7 and March 27, 2014 Acoustic Doppler current-profiler (ADCP) surveys conducted by Public Works and Government Services Canada (PWGSC). • Interpretation of airphotos of the lower Fraser River spanning 1938 to 2009. • Review of bathymetric surveys conducted by Public Works and Government Services Canada (PWGSC) in 1988/89, 2000/01, 2008/09, and 2014. | Baseline Data Collection Technical Volume - River Hydraulics and River Morphology Study | Part B Effects Section Section 4.1.2.1, page 4.1.6 Section 16.2, page 8 |
| | | The hydrodynamic program TELEMAC-3D was used to compute hydraulic conditions in the lower Fraser River. Scour and deposition around the Tunnel were computed by coupling the sediment transport and morphodynamic model SISYPHE to TELEMAC-3D. | Potential Effects Technical Volume - River Hydraulics and River Morphology Study | Part B- Effects Section Section 4.1.3.2, pages 4.1-18 to 4.1-19 Section 16.2, page 8 to 9 |
| | | In B.C., the ownership of water is vested in the Crown as stated in Section 5 of the Water Sustainability Act [SBC 2014] CHAPTER 15, the primary provincial statute regulating water resources. Since the Project involves potential works in or about the Fraser River, Sections 11 and 12 of the Water Sustainability Act and associated Water Sustainability Regulation would apply to such activities. Section 46 of the Water Sustainability Act, which provides additional protection to surface water bodies, beyond what is ensured by the Environmental Management Act and Waste Discharge Regulation, by prohibiting the introduction of foreign matter into streams and creating associated penalties, is also relevant in the Project context. | Regulatory Context | Part B – Effects, Section 4.1.2.2, page 4.1-6 |
| | | Details on the river hydraulics and morphology effects assessment will be included in the following technical volume appended to the Application: <ul style="list-style-type: none"> ▫ River Hydraulics and River Morphology Technical Study | Technical Volume - River Hydraulics and River Morphology Study | Section 16.2 |
| Section 4.1.3 Page 24 | Potential Effects | The Application will identify potential effects of the Project on water levels, velocities, and flow patterns (river hydraulics), and their influence on sedimentation and erosion (morphology) within the lower Fraser River in a manner consistent with section 3.4 Potential Effects of this AIR. | Potential Effects | Part B – Effects, Section 4.1.3, pages 4.1-16 to 4.1-25 |
| Section 4.1.4 Page 24 | Mitigation Measures | The Application will identify measures to avoid, manage or otherwise mitigate potential adverse effects to river hydraulics and river morphology in a manner consistent with Section 3.5 Mitigation Measures of the AIR. Relevant management plans will be referenced, and linkages to other sections in the Application will be identified. | Mitigation Measures | Part B – Effects, Section 4.1.4, page 4.1-25- 4.1-26 |
| Section 4.1.5 | Residual Effects and their | If any residual effect on river hydraulics and morphology is identified, it will be described in sufficient detail to support the assessment of potential effects on the following ultimate receptor VCs: | Residual Effects | Part B – Effects, Section |

| AIR Section and Page No. | AIR Section Title | AIR Section Language | Application Section Title | Application Volume, Section, Sub-Section, Page No. |
| Section 4.10.2 Page 57 | Existing Conditions | The Application will summarize existing conditions in a manner consistent with Section 3.3 Existing Conditions of the AIR. | Existing Conditions | Part B – Effects, Section 4.10.2, pages 4.10-9 to 4.10-12 |
| | | The following general approach has been adopted for collection of baseline information on atmospheric noise: • Continuous noise monitoring (for 24-hour, 48-hour, and shorter periods) at select noise-sensitive receptor sites in the vicinity of the Project to establish existing ambient noise conditions. | Methodology | Part B – Effects, Section 4.10.1.2, pages 4.10-4 to 4.10-7 |
| | | Community noise effects associated with provincial highway projects in B.C. are addressed in the Ministry of Transportation and Infrastructure’s 2014 <i>Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways</i> . | Methodology | Part B – Effects, Section 4.10.2.1, page 4.10-5 |
| | | The following technical documents will be appended to the Application to support the atmospheric noise effects assessment: ▫ Atmospheric Noise Study - Technical Details | Technical Volume - Atmospheric Noise Study | Section 16.6 |
| Section 4.10.3 Page 58 | Potential Effects | The Application will identify potential effects of the Project on atmospheric noise in a manner consistent with Section 3.4 Potential Effects of the AIR. | Potential Effects | Part B – Effects, Section 4.10.3, pages 4.10-13 to 4.10-16 |
| | | A conservative traffic scenario, based on a review of the range of possible future conditions, will be used in predicting potential Project-related effects on atmospheric noise. Rationale behind traffic volume assumptions used in predicting Project-related effects on atmospheric noise will be provided in the Application. | Technical Volume - Atmospheric Noise Study | Section 16.6 |
| Section 4.10.4 Page 58 | Mitigation Measures | The Application will identify measures to avoid, manage or otherwise mitigate potential adverse effects to atmospheric noise in a manner consistent with Section 3.5 Mitigation Measures of the AIR. Relevant management plans will be referenced, and linkages to other sections in the Application will be identified. | Mitigation Measures | Part B – Effects, Section 4.10.4, pages 4.10-17 to 4.10-20 |
| Section 4.10.5 Page 58 | Residual Effects and their Significance | If any residual effect on atmospheric noise is identified, it will be described in sufficient detail to support the assessment of potential effects on the following ultimate receptor VCs: ▫ Human health ▫ Terrestrial wildlife ▫ Land Use | Residual Effects | Part B – Effects, Section 4.10.5, pages 4.10-21 to 4.10-30 |

| Section 5.1 Page 60 | Traffic | <p>As a transportation project intended to address existing traffic challenges in the Highway 99 corridor, the assessment of traffic relates to primary Project objectives including reducing congestion, improving travel time and reliability, improving safety, supporting goods movement, supporting transit, and accommodating pedestrians and cyclists. The assessment of traffic in the Application focuses on the potential influence of Project-related construction on traffic and the influence of the new bridge and upgraded highway on traffic conditions along the Highway 99 corridor. An overview of the influence of tolling on future trends in traffic will be included.</p> <p>Traffic will be studied as an IC in the context of effects of the Project on the following ICs and VCs:</p> <ul style="list-style-type: none"> ▫ Air quality (IC), which will inform the assessment of Project-related effects on human health and terrestrial wildlife, which will be assessed as VCs. ▫ Atmospheric noise (IC), which will inform the assessment of Project-related effects on human health and terrestrial wildlife, which will be assessed as VCs. ▫ Land use, which will be assessed as a VC. ▫ Terrestrial wildlife, which will be assessed as a VC. | Traffic | Part B – Effects, Section 5.1, page 5.1-1 |
| | | <p>The traffic study will focus on projected traffic conditions within the Project corridor during Project construction and operation. Results of the study will be discussed in terms of the following:</p> <ul style="list-style-type: none"> - Traffic volumes - Mode share (distribution/break-down) - Travel time and reliability | Methodology | Part B – Effects, Section 5.1.1.2, pages 5.1-2 to 5.1-3 |
| Section 5.1.1 Page 61 | Context and Boundaries | The Application will identify the spatial, temporal, administrative and technical study area boundaries, as applicable to traffic, including maps (Figure 5.1-1 Traffic Local and Regional Assessment Areas), in a manner consistent with Section 3.2 Assessment Boundaries of the AIR. | Assessment Boundaries | Part B – Effects, Section 5.1.1.3, pages 5.1-3 to 5-1.7 |
| Section 5.1.2 Page 63 | Existing Conditions | The Application will summarize existing conditions in a manner consistent with Section 3.3 Existing Conditions of the AIR. In addition to existing conditions in the LAA, the existing conditions for Traffic will identify current and future trends, with and without the Project, related to traffic in the LAA and directly adjacent portions of the regional road network. | Existing Conditions Appendix B - Design Hourly Volumes | Part B – Effects, Section 5.1.3, pages 5.1-2 to 5.1-20 Section 5.1, Appendix B |
| | | <p>The following general approach has been adopted for collection of baseline information on traffic. Existing conditions and traffic forecasts for relevant areas in the LAA and RAA have been developed based on a program of:</p> <ul style="list-style-type: none"> • Desk top research • A number of key sources of truck traffic information were reviewed including traffic count station data, TransLink screenline surveys, and the Metro Vancouver Truck Classification and Dangerous Goods Survey (Transport Canada, 2014). • Regional transportation and growth management plans, including the Metro Vancouver Regional Growth Strategy (RGS) and TransLink's Regional Transportation Strategy (RTS) were reviewed to identify trends in population and employment growth in Richmond, Delta and Surrey as well as future regional transportation infrastructure considerations that may influence existing and future traffic conditions in the LAA and RAA. • Data collection • Origin and Destination surveys - A detailed analysis of 2013 and 2014 origin-destination travel patterns was performed for GMT | Baseline Data Collection | Part B – Effects, Section 5.1.3, pages 5.1-7 |

APPLICATION SUMMARY

Project Overview

The British Columbia (B.C.) Ministry of Transportation and Infrastructure (Ministry) is proposing the George Massey Tunnel Replacement Project (Project) to address current safety and congestion challenges, meet forecast population and employment growth, and ensure Highway 99 continues to serve regional, provincial, and national transportation needs.

Located on the Highway 99 corridor, the George Massey Tunnel (Tunnel) is an important link in the regional and provincial transportation system, carrying an average of 80,000 vehicles each day. It is a vital goods movement route that fuels our national, provincial, and regional economies, and is the main access route for businesses in City of Richmond (Richmond), Corporation of Delta (Delta), City of Surrey (Surrey), and Tsawwassen First Nation (TFN).

The Tunnel provides an essential link between the municipalities of Richmond and Delta, and connects to gateways such as the Vancouver International Airport (YVR), Douglas (Peace Arch) and Pacific Highway Canada–United States border crossings, BC Ferries' Tsawwassen terminal, Deltaport, and Boundary Bay Regional Airport.

The Project is designed to reduce congestion and improve travel times and reliability for commuters, transit, commercial vehicles, and tourists; improve safety; provide new travel options for cyclists and pedestrians; and provide capacity for improved transit. Proposed works include:

- Replacing the Tunnel with a new bridge spanning the Fraser River South Arm and Deas Island.
- Replacing the existing Westminster Highway, Steveston Highway, and Highway 17A interchanges.
- Widening Highway 99 to accommodate dedicated transit/high occupancy vehicle (HOV) lanes.
- Constructing integrated transit stops, dedicated ramps, and other transit-priority measures.
- Providing multi-use pathways on the bridge for cyclists and pedestrians.
- Decommissioning the Tunnel.

Environmental Assessment Process

The Project is being reviewed under Part 5 and Part 8 of the *Reviewable Projects Regulation* of the B.C. *Environmental Assessment Act* (B.C. *EAA*) because of the area of foreshore and submerged land likely to be disturbed during Tunnel decommissioning (i.e., greater than 2 ha) and the continuous distance over which extra lanes will be added to the existing public highway (i.e., greater than 20 km).

The B.C. Environmental Assessment Office (EAO) issued an Order under section 10 of B.C. *EAA* for the Project, on Dec 16, 2015, indicating the Project requires an environmental assessment, and an Order under section 11 of B.C. *EAA*, on January 7, 2016, describing the requirements for public consultation on the Project Description and Key Areas of Study document. A subsequent order under section 11 of B.C. *EAA* was issued on March 7, 2016, which described the scope of the Project and the scope of the assessment under B.C. *EAA*.

While the Project does not trigger a federal review under the *Canadian Environmental Assessment Act, 2012*, federal involvement in the Project will include consultation with Fisheries and Oceans Canada, Environment and Climate Change Canada, Transport Canada, and the Vancouver Fraser Port Authority, and issuance of a permit, approval, or authorization from these agencies as applicable.

Consultation

Since September 2012, the Ministry has been conducting technical analyses, raising awareness about the Project, engaging interested parties in dialogue, and responding to Project-related enquiries. Input obtained through these consultation and engagement processes has assisted in:

- Identifying the new bridge and associated highway improvements as the most appropriate approach to meeting Project objectives.
- Identifying complementary improvements that will support more sustainable modes of transportation in the Highway 99 corridor including transit, HOV, cycling and walking.
- Identifying environmental, socio-economic, health and heritage values to be considered and addressed during Project planning, environmental assessment, construction, and operation.

Project-related consultation has provided valuable insights from a broad range of organizations and individuals, including Aboriginal Groups, municipalities, Metro Vancouver, TransLink, the agricultural community, first responders, recreational groups, local businesses, local residents, cyclists, environmental groups, marine users, and other interested individuals.

Public Consultation Activities To Date

Ministry-led Consultation

The Ministry undertook three phases of Project consultation, each of which included open houses complete with display boards, discussion guides, and feedback forms:

- **Phase 1 Consultation: Understanding the Need** (November/December 2012) – Conducted early in the Project’s planning process, this phase of consultation sought input to gain a better understanding of travel needs and community considerations for developing replacement options. Congestion relief and economic growth were identified as the most important factors when considering solutions for the Tunnel. Doing nothing was not viewed as an option. This input was used to help develop a draft project scope and potential replacement scenarios.
- **Phase 2 Consultation: Exploring the Options** (March/April 2013) – Sought input on five potential replacement scenarios, which were developed in consideration of Phase 1 input, and the criteria to evaluate these scenarios. During this phase, participants indicated a preference for a new bridge along the existing Highway 99 corridor. They also wanted the Ministry to make sure the new crossing includes improvements for transit, cyclists and pedestrians.
- **Phase 3 Consultation: Project Definition Report** (December 2015/January 2016) – Sought input on the Project Definition Report including the proposed Project scope, Project success measures, funding options, and traffic management during construction. Input from the Phase 3 consultation was used to finalize the Project scope and support development of the Application.

Public communication measures have included the following:

- **Project Office, Website and Telephone Information Line:** A Project website (www.masseytunnel.ca) and a Project-related electronic database (e-database) were established in November 2012 to provide information about the Project, and a Project Office with full-time community relations staff was opened in Richmond in January 2014.
- **Stakeholder Outreach:** The Ministry has engaged in a variety of additional outreach activities with key stakeholders. This has involved over 100 presentations on request to business and community groups; and extensive meetings with key stakeholder groups to gather input in support of developing conceptual designs for the new crossing, including more than 85 meetings with City of Richmond and Corporation of Delta staff, and more than 30 meetings with Metro Vancouver staff.
- **Advertising and Media Relations:** The Ministry maintains an ongoing and open dialogue with the media, including interviews with the Minister of Transportation and Infrastructure, the Executive Project Director, and other Project spokespersons.

Pre-Application EA Consultation

As part of the pre-Application phase of the environmental assessment, the EAO held a public comment period from January 15, 2016 to February 15, 2016 that sought input on the Project Description and Key Areas of Study document for the Project. Two open houses, led by EAO, were held in support of the 31-day public comment period: on January 26, 2016 in Richmond and January 27, 2016 in Delta. Project and EAO staff and the Ministry's technical experts were present to answer questions on the Project. Following the public comment period, the Ministry provided responses to all questions raised, and these responses were posted on the provincial electronic Project Information Centre (http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_home.html). Another 30-day public comment period led by the BC EAO will be held during the review of the Application. The Ministry will be required to respond to comments received at that time.

Aboriginal Consultation Activities To Date

Two phases of consultation with Aboriginal Groups that may be affected by the Project or that have Aboriginal Interests within the Project alignment, included those as set out on the section 11 Order, are complete: initial consultation (January 2013 to December 2015) and pre-Application consultation (December 2015 to July 2016).

The primary objective of the Ministry's Aboriginal consultation program is to maintain and, where possible, enhance respectful, positive, and productive relationships with Aboriginal Groups while meeting all applicable legal, policy, and regulatory requirements in relation to the Project. Additional objectives include providing opportunities for Aboriginal Groups to provide meaningful input for consideration in the environmental assessment and permitting processes and undertaking consultation with Aboriginal Groups in accordance with the Project's Aboriginal Consultation Plan. The Ministry provided participation funding in response to requests by all Schedule B Aboriginal Groups during initial Project-related discussions for funding to support participation in the Project review process, and undertook the appropriate planning and discussions with Aboriginal Groups.

To date, more than 80 meetings have taken place with Aboriginal Groups involved with the Project. The Ministry will continue to work with Schedule B Aboriginal Groups during the Application Review Phase to further refine community-specific consultation activities. Post Environmental Assessment Certificate (EAC) consultation will continue from issuance of the EAC to the date when all Project-related permits have been issued.

Environmental Effects Assessment Method

The Application follows a standard approach to selecting appropriate valued components (VCs) and assessing the Project's effects on each VC, consistent with EAO guidance. Any residual environmental effects of the Project are characterized using specific criteria (context, magnitude, geographic extent, duration, frequency and reversibility) that are defined for each VC (described in detail in the Application). The significance of Project-specific residual effects is determined for each VC using relevant thresholds, regulatory standards, or professional judgment. The significance of the Project's contribution to cumulative effects, in combination with other past, present or future projects and activities, is also assessed, where relevant.

The following VCs were selected for assessing Project-related effects:

- Environmental
 - Fish and fish habitat
 - At-risk amphibians
 - Marine mammals
 - Vegetation
 - Terrestrial wildlife
- Socio-economic
 - Land use
 - Marine use
 - Agricultural use
 - Visual quality
- Heritage
 - Heritage resources
- Health
 - Human health

In cases where potential Project-related effects on a component are part of a longer effects pathway, those components were classified as intermediate components (ICs) and studied to support the assessment of Project-related effects on the ultimate receptor VC. The following components were assessed as ICs:

- River hydraulics and river morphology
- Surface water and sediment quality
- Underwater noise
- Air quality
- Atmospheric noise
- Traffic

Key Conclusions

Key findings of the assessments conducted on each of the selected VCs and ICs are discussed.

River Hydraulics and River Morphology

Potential Project-related effects on river hydraulics and river morphology considered in the assessment include changes in water levels, velocities, and flow patterns (hydraulics) and subsequent influence on sedimentation and erosion (morphology). River hydraulics and river morphology was assessed as an IC to support the assessment of potential effects of the Project on fish and fish habitat, marine mammals, and marine use. Key findings of this assessment are presented below:

- The proposed bridge will have a clear-span over the Fraser River South Arm, which avoids potential changes to river hydraulics or river morphology resulting from the new structure.
- The Fraser River South Arm is dynamic with scour in the order of several meters during freshet and migrating sand dunes with heights of up to four metres.
- Removal of the Tunnel is not expected to result in changes in water level or affect flow splits between the main channel and nearby channels.
- Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor.

- Tunnel removal is expected to result in temporary bed lowering between the Tunnel and the Lulu Island–Delta watermain; however, with monitoring and mitigation, no effect on the watermain is expected.
- Measures proposed to mitigate potential effects on the Lulu Island-Delta watermain include early engagement and coordination with Metro Vancouver, as well as riverbed monitoring and procedures for priority scour protection repairs if required.
- No Project-related long-term residual effects or cumulative effects on river hydraulics or river morphology are expected.

Sediment and Water Quality

Potential Project-related effects on sediment and water quality considered in the assessment include temporary increases in turbidity as a result of construction activities, including installation of bridge foundations along the edge of Deas Slough, Tunnel removal, and decommissioning of the Deas Slough Bridge. Sediment and water quality was assessed as an IC to support assessment of potential Project-related effects on fish and fish habitat, marine mammals, vegetation, and at-risk amphibians. Key findings of the assessment are presented below:

- The new bridge will have a clear-span, which reduces potential Project-related effects on sediment and water quality in the Fraser River South Arm.
- Minor, temporary increases in turbidity in the Fraser River South Arm, as compared with baseline conditions, are expected during Tunnel decommissioning.
- No appreciable change in water quality related to the re-suspension or re-distribution of sediments during Tunnel decommissioning is anticipated.
- Applying mitigation, including timing windows for undertaking in-stream works, will avoid or minimize potential effects of Project-related changes in water quality on fish and fish habitat.
- Elements of the Project design, including the use of biofiltration ponds, will provide a benefit to ambient water and sediment quality in the Fraser River by improving the level of treatment of surface runoff from Highway 99.
- No Project-related post-construction residual effects or cumulative effects on sediment and water quality are expected.

Underwater Noise

The Project involves in-water or near-shore construction activities such as pile driving, soil stabilization, and Tunnel removal that have the potential to influence underwater noise levels in the Fraser River South and Deas Slough, which could affect fish and marine mammals in these waters. Underwater noise was assessed as an IC to support the assessment of fish and fish habitat and marine mammals. Key findings of this assessment are summarized below:

- The Project area is highly developed and existing underwater noise levels in the Fraser River, dominated by noise from vessels transiting the river, are relatively high.
- The proposed bridge will have a clear-span over the Fraser River and Deas Slough, minimizing instream works and the potential for underwater noise effects associated with construction.
- Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Underwater noise can be mitigated effectively by scheduling construction activities in a manner that minimizes potential effects.
- Applying mitigation, including underwater noise monitoring and management during construction, will minimize the potential for Project-related changes in underwater noise conditions to affect fish or marine mammals.
- No post-construction residual effects or cumulative effects on underwater noise conditions are expected.

Fish and Fish Habitat

The Fraser River South Arm, tidal sloughs, and upland watercourses support a range of fisheries values. The Ministry has taken steps during Project planning and design, including proposing a clear span structure across the Fraser River South Arm and no direct run-off from the bridge to the river, to avoid or minimize Project-related impacts on fish and fish habitat. Potential effects on fish and fish habitat include those related to potential changes in water quality, underwater noise, and riparian and aquatic habitat as a result of Project-related construction activities.

Key findings of the assessment of the assessment of potential Project-related effects on fish and fish habitat are summarized below:

- The small area of fish habitat affected by the Project will be offset by proposed habitat enhancements, including restoring Green Slough to its historic alignment, resulting in a net environmental benefit for fish and fish habitat.

- Mitigation, including timing windows for undertaking in-stream works and other measures outlined in Project-related Environmental Management Plans, will ensure that potential effects on fish and fish habitat are effectively addressed.
- Given the disturbed nature of much of the Project alignment, revegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by:
 - Improvements to local water quality through Project-related improvements in stormwater management.
 - Removal of non-native species.
 - Replanting with species that provide habitat value for fish and wildlife.
- Adherence to prescribed least-risk timing windows and implementation of standard industry practices and mitigation measures will effectively minimize effects on fish in the Project area such that there is no anticipated effect on population integrity.
- No overlap or interaction of Potential Project-related effects with effects of other projects or activities is expected; thus no cumulative effects are anticipated.
- No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

At-risk Amphibians

The Project is located primarily within the existing, previously disturbed Highway 99 right-of-way, and suitable habitat within the Project alignment is limited. Potential effects on at-risk amphibians include those related to potential changes in water quality in upland watercourses.

Key findings of the Project-related at-risk amphibian assessment include the following:

- At-risk amphibians were not detected within the Project alignment during field studies undertaken in 2014 and 2015. The potential for at-risk amphibians to occur within the Project alignment is low.
- Applying mitigation, including least-risk timing windows, and adherence to standard practices for undertaking in-stream works and highway maintenance activities, will ensure that potential Project-related effects on at-risk amphibians are addressed.
- No Project-related residual or cumulative effects on at-risk amphibians are expected.

Marine Mammals

Marine mammals, specifically harbour seals and sea lions, are known to use marine areas within and adjacent to the Project alignment. Other species of conservation interest, including southern resident killer whales, do not occur in the Fraser River. Potential Project-related effects on marine mammals are primarily associated with underwater noise during in-stream construction activities, including Tunnel decommissioning. Key findings of the assessment of potential Project-related effects on marine mammals are summarized below:

- Underwater noise in the Fraser River South Arm from existing sources currently exceed thresholds for disturbance to marine mammals approximately 20% of the time.
- The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.
- Best management practices will be applied to activities such as impact pile driving to ensure sound thresholds for the protection of marine mammals are adhered to. Applying such measures to mitigate and monitor Project-related underwater noise will ensure that potential effects on marine mammals are effectively addressed.
- Project-related construction activities are not anticipated to result in population-level effects to marine mammals, including species at risk, and no residual effects on marine mammals are anticipated.
- No Project-related residual or cumulative effects on marine mammals are expected.

Vegetation

The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development. There are, however, small portions of the Project alignment that support native vegetation, and an assessment of potential Project-related effects on vegetation was undertaken. An overview of the key findings of this assessment is provided below:

- The Project alignment has limited potential to support terrestrial and wetland plant species and ecosystems, including those considered to be (provincially) at-risk.
- Project components and activities will be primarily located within the existing Highway 99 ROW, where the vegetation consists mainly of grassy, mowed verges.
- No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.
- Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily a cattail marsh and estuary marsh, which occurs in the vicinity of the Project.

- Creating comparable habitat within the Project alignment will offset the unavoidable potential Project-related effect, which is limited to a small reduction in area of the cattail marsh that overlaps with Project components.
- Applying best practices such as flagging of at-risk ecosystems to avoid encroachment during construction and replanting of disturbed areas with native species will ensure that Project-related effects on vegetation are effectively addressed.
- With the application of mitigation, no Project-related residual or cumulative effects on vegetation are expected.

Terrestrial Wildlife

Terrestrial wildlife along Highway 99 consists primarily of common species of raptors, riverine birds, and small mammals. Potential effects on terrestrial wildlife, including construction-related effects on habitat, and disturbance effects and collision risk during the operational phase, were assessed. Key findings of this assessment are summarized below:

- Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge.
- No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.
- The application of best practices during future stages of design and construction will largely avoid or mitigate Project-related effects on wildlife and wildlife habitat.
- Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed.
- Installation of flight deflectors such as hedgerows at appropriate locations along the highway will mitigate potential Project-related collision risk for barn owls.
- Nesting opportunities provided by the new bridge will offset the loss of barn swallow nesting habitat due to removal of the Deas Slough Bridge.
- No significant Project-related residual effects or cumulative effects on terrestrial wildlife are expected.

Air Quality

Recent and projected trends in regional air quality in the Lower Fraser Valley indicate that, for most parameters, air quality has improved as a result of reductions in emissions from vehicles as new emission control technologies are phased in. This trend in improvements in air quality are expected to continue in the future, with or without the Project; however, Project-related reduction in idling due to congestion and consequent reduction in emissions, as well as better dispersion of vehicle emissions from the bridge are anticipated to result in further improvement in air quality.

Key findings of the Project-related air quality assessment are summarized below:

- Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include:
 - A 35 % reduction in particulate matter emissions, as compared with a 14 % reduction without the Project.
 - A 47 % reduction in volatile organic compound (VOC) emissions, as compared with a 40 % reduction without the Project.
- No exceedances of the current most-stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.
- The new bridge will allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.
- Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.
- Construction-related effects on air quality will be minimized through implementation of recognized mitigation measures and best management practices that have proven to be effective on other transportation infrastructure projects in the Lower Mainland.
- Potential effect of Project-related construction on air quality are expected to be low in magnitude, and confined to active construction areas. All effects will be temporary, of short-duration, and fully reversible.
- No Project-related post-construction residual effects or cumulative effects on air quality are expected.

Atmospheric Noise

Ambient noise levels in the Project area are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Trains, aircraft, marine, and agricultural activities also contribute to ambient noise in and around the Project area. However, there are areas along the corridor where noise conditions will change as a result of Project-related construction and operation. Key findings of the assessment of such potential Project-related changes are summarized below:

- Construction-related noise can be addressed by applying mitigation and best practices, including the following, that have proven to be effective on other recent transportation infrastructure projects in the Lower Mainland:
 - Equipment and activity restrictions to minimize noise emissions.

- Noise monitoring program.
- Processes for community communication, engagement, and adaptive management.
- Residual effects during construction will be temporary and vary from low to high depending on the distance from the construction site and nature of construction activity. Effects will be short-term during construction of interchanges etc., and of moderate term during pile installation for the new bridge. All construction-related effects on atmospheric noise will be temporary and fully reversible.
- Appropriate mitigation measures will be implemented at select locations to address Project-related change in noise levels during operation.
- With the application of mitigation, ambient noise levels during operation are expected to be lower than current levels—on average by 4 dBA at residences and 1.5 dBA at schools and places of worship.
- Noise levels at parks adjacent to the Project, including Deas Island Regional Park, are expected to increase by varying degrees dependent on the distance from the highway, but will generally remain below levels that warrant mitigation consideration for residential and institutional use.
- No cumulative changes of readily measurable or perceptible magnitude are predicted within the Project alignment.

Traffic

The Project has been designed to address issues related to current and future traffic safety, congestion and reliability, and to help achieve regional mode share targets by facilitating travel across the Fraser River by transit, HOVs, cycling and walking. Changes in traffic conditions, during construction and operation, have been estimated to support the assessment of potential effects on terrestrial wildlife, air quality, atmospheric noise, land use, and human health. Key findings of this assessment are summarized below:

- Impacts on traffic during Project construction will be minimized through the implementation of recognized mitigation measures and best management practices.
- Temporary, localized changes in traffic volume, mode share, and travel time and reliability can be anticipated during construction as construction-related traffic interacts with regular flows. These low to moderate magnitude changes could occur frequently during construction, and are expected to be short to moderate term in duration. All construction-related effects are fully reversible.
- During operations, the Project will provide travel time savings of 25-35 minutes per day for commuters, improve safety with a forecast 35% reduction in collisions, and support provincial and regional strategies to encourage mode shift to transit and carpooling.

- As proposed, Project-related improvements, which include better travel mode options, and tolling will help moderate traffic growth while effectively serving forecast demand at the crossing.
- The Project will have a positive effect on future traffic conditions along the Highway 99 corridor.

Marine Use

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, sorting and booming, as well as commercial, recreational and aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place in the vicinity of the Project.

Key findings of the assessment of Project-related effects on marine include the following:

- The proposed clear span crossing of the Fraser River will avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span, improving navigation in and out of the slough.
- Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.
- Working with Aboriginal Groups and key stakeholders to develop a Marine Access Management Plan will mitigate temporary impacts to marine use associated with Project construction.
- Key mitigation considerations to ensure marine use activities can continue in a safe manner during Project construction include:
 - Communications protocols to establish and advise of in-stream construction activities.
 - Lighting and marking for safe navigation.
 - Establishing navigation protection zones during construction to avoid or minimize impacts on marine use.
- Potential construction-related residual effects of the Project on marine use are considered to be low to moderate in magnitude, local in extent, short-term in duration, occasional in frequency, and reversible.
- Temporary residual effects of Project construction on marine use are not considered significant.
- No overlap or interaction of Potential Project-related effects with effects of other projects or activities is expected; thus no cumulative effects are anticipated.
- Project-related changes are expected to have a positive effect on marine use in Deas Slough during the operational phase.

Land Use

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta. Key findings of the land use assessment are summarized below:

- The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way.
- Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill.
- The Project is consistent with local and regional land use plans, will support denser, land-intensive, high-quality forms of development along the Highway 99 corridor, consistent with such plans.
- The Project is not anticipated to affect the planned distribution of regional population and employment growth predicted in Metro Vancouver's regional growth strategy, overall regional population growth and distribution or current trends in industrial land use and development.
- Once the new bridge becomes operational, the recreational experience on adjacent land is expected to change due to:
 - Improved connectivity across Deas Island Regional Park resulting from removal of the Tunnel portals.
 - Improvements in local air quality, Deas Island shoreline restoration and revegetation of areas that currently support highway infrastructure.
 - Shading adjacent to the bridge, overhead noise, and changes in local viewscales.
- The Project will not result in changes to existing land use beyond the small amounts of land that are required outside of the existing right-of-way.
- Potential temporary effects on existing land use during construction will be addressed by developing and implementing a Construction Traffic Management Plan.
- No significant Project-related residual effects or cumulative effects on land use are expected.

Agricultural Use

Agriculture is the predominant use of land adjacent to the Highway 99 ROW in Richmond and Delta. Agricultural land borders about two thirds of the Project alignment. Potential Project-related effects on agricultural use include requirements for agricultural land as well as indirect effects, such as changes in drainage and other farm infrastructure. Key findings of the Project-related agricultural use assessment are presented below:

- The Project has been designed to accommodate all proposed works predominantly within the Highway 99 ROW, minimizing the need for land acquisitions to the extent possible.
- The Ministry has identified suitable land parcels that will be made available for agricultural use to offset the acquisition of small portions of farmland for the Project. These parcels are located adjacent to existing farm fields and can be restored to comparable land capability, enhancing their agricultural potential.
- Project-related offsetting is expected to result in a net gain of land for agricultural use.
- The Project is expected to result in potential changes to the boundaries of a small number of farms. Potential effects associated with these changes will be mitigated through measures such as parcel consolidation and using elevated guideways to minimize land requirements.
- Agricultural operations along the Project alignment are expected to benefit from Project-related improvements to irrigation and drainage systems as well as increased reliability in getting agricultural goods to market.
- Potential residual effects of the Project are limited to changes in parcel boundaries of three farm fields. These effects can be largely offset by consolidating the parcels with adjacent properties such that the parcels can continue to be farmed.
- No overlap or interaction of Project-related residual effect with effects of other projects or activities is expected; thus, no cumulative effects are expected.
- No significant Project-related residual effects or cumulative effects on agricultural use are expected.

Visual Quality

The new bridge will add visual features to the landscape and will change visual conditions adjacent to the Project alignment. Replacement of interchanges has the potential to change visual conditions at these locations. Key findings of the assessment of potential Project-related effects on visual quality are presented below:

- At distances greater than one kilometre, the bridge deck will merge with the natural landscape and the main visual features will be the bridge towers.

- Vegetated buffers will minimize visual effects to residential developments within close proximity to the bridge in Delta.
- Changes in visual quality at interchanges will be minor as visual quality in such areas is currently influenced by existing transportation infrastructure.
- After the implementation of mitigation measures, residual changes in conditions are predicted at a small number of viewpoints located in the immediate vicinity of the new bridge.
- Overall, the new bridge is expected to result in changes in visual conditions that are moderate in magnitude and site-specific in extent.
- No overlap or interaction of Potential Project-related effects with effects of other projects or activities is expected; thus no cumulative effects are anticipated.
- No significant Project-related residual effects or cumulative effects on visual quality are expected.

Heritage Resources

The Project is located in an area where substantial historical development has occurred and the majority of the local assessment area is characterized as having low archaeological potential.

Key findings of Project-related assessment of heritage resources are summarized below:

- The Project is located in an area where substantial historical development has occurred, and the majority of the Project alignment is characterized as having low archaeological potential.
- No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.
- The development and implementation of an Archaeological and Heritage Resources Management Plan, which will include a chance-find procedure, will avoid impacts to previously unknown or unidentified heritage resources that may be encountered during Project construction and operation.
- No Project-related residual effects or cumulative effects on heritage resources are expected.

Human Health

A human health risk assessment (HHRA) was used to support the assessment of health. The HHRA focused on health considerations associated with Project-related changes in air quality and noise conditions. The Ministry also undertook a health impact assessment (HIA) to evaluate the influence of the Project on broader determinants of human health. Key findings of studies related to health are summarized below:

- Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health.
- Implementing mitigation measures to address traffic-related noise during Project operation will avoid increases in human health risk, and in some cases will result in improvements over current conditions.
- Proven mitigation measures, effectively used during the construction of projects such as the South Fraser Perimeter Road and Port Mann/Highway 1 Improvement project, will be implemented to ensure that temporary increases in ambient noise levels and air emissions during construction do not result in health effects.
- The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options.
- The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased opportunities for active and public transportation, improved traffic safety, improved connectivity and access, improved emergency response, and economic development opportunities.
- Future Project-related engagement with Aboriginal Groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.
- Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations and emergency response.
- With the application of mitigation, no Project-related adverse effects or cumulative effects on human health are expected.

Accidents and Malfunctions

The primary environmental effect that could result from accidents and malfunctions that may occur during Project-related construction and operation would be the release of deleterious substances into terrestrial or aquatic habitats. Mitigation measures, including Project design, implementation of a Construction Environmental Management Plan, and contingency measures (e.g., spill prevention and emergency response training, erosion control), will minimize the potential for adverse effects resulting from accidents and malfunctions.

Effects of the Environment on the Project

Natural events with the potential to affect the Project (e.g., damage to highway and bridge infrastructure), lead to traffic closures and adversely affect environmental components include erosion and scour, extreme weather, flooding, seismic events, and climate change. The Project will be designed, constructed, and operated in a manner that addresses potential adverse effects of climate change, including temperature rise, increased precipitation, and sea-level rise, on Project components. Adherence to appropriate engineering design standards will ensure that potential effects of the environment on the bridge and highway improvements will not affect safety or functionality.

Aboriginal Consultation

Aboriginal Interests, defined as asserted or determined Aboriginal rights, including title, and treaty rights, are known to overlap or lie in the vicinity of the Project corridor. Potential adverse effects on the exercise of Aboriginal Interests as a result of Project construction and operation have been identified.

Mitigation measures to address potential Project-related effects on ICs and VCs associated with the exercise of Aboriginal Interests are expected to be effective. With the application of mitigation, potential effects on the exercise of Aboriginal Interests are predicted to be negligible except in specific cases during Project construction and operation. To address potential effects during Project construction and operation, the development of an Archaeological and Heritage Resources Management Plan is proposed.

In addition to mitigation measures proposed to address potential effects on ICs and VCs, ongoing engagement between the Ministry and Schedule B Aboriginal Groups will be undertaken. Such engagement will take place during Application Review and, if the Project is approved, following the issuance of an EAC. Engagement will involve consultation on management plans and monitoring programs, related to the exercise of Aboriginal Interests, and potential project agreements.

Ongoing engagement is also proposed to address other matters of environmental, economic, social, heritage, and health concern raised Aboriginal Groups during the pre-Application period. With this ongoing engagement, residual effects on the exercise of Aboriginal Interests or other matters of concern as a result of the Project are not expected.

Conclusion

The proposed Project is being advanced in order to address substantial traffic and safety challenges in the Highway 99 corridor that affect the efficient movement of people and goods within the region. Addressing these challenges will result in a number of economic, environmental, social and health benefits including:

- Travel time and reliability improvements for all users
- Improvements in local air quality
- Reductions in vehicle collisions and safety risk
- Improvements in access and mobility for local agricultural operations
- Improvements in access to transit, carpooling, and active modes of transportation
- Economic benefits including employment and economic growth

In addition to addressing traffic challenges in the Highway 99 corridor, the Project represents an opportunity to enhance environmental values that have been affected by previous development including restoration of Green Slough to its historic alignment and enhancements to habitat in Deas Slough.

The environmental assessment undertaken for the Project identified other environmental and socio-community values that may potentially be affected by Project construction and operation. Where applicable, steps have been taken during Project planning to avoid such effects. Additional mitigation during Project design, construction, and operation is proposed to address potential adverse effects. After mitigation implementation, including potential offsetting strategies and monitoring programs, the Ministry has assessed that Project construction and operation will not result in significant adverse effects.

Part A – Introduction

1.0 Overview of Proposed Project and Proponent

Introduction

The British Columbia (B.C.) Ministry of Transportation and Infrastructure (Ministry) is proposing the George Massey Tunnel Replacement Project (Project) to address current safety and congestion challenges, meet forecast population and employment growth, and ensure Highway 99 continues to serve regional, provincial, and national transportation needs.

The proposed Project involves replacing the George Massey Tunnel (Tunnel) with a new bridge spanning the Fraser River South Arm and Deas Island, decommissioning the Tunnel, and improving Highway 99 between Bridgeport Road in Richmond and Highway 91 in Delta.

The purpose of this section of the Application is to provide information to support the assessment of the proposed Project, including:

- Information on the Project Proponent.
- The Project purpose and rationale, including overview of key Project drivers.
- Detailed information on key Project elements, including activities to be undertaken to facilitate construction and operation of the Project.
- Additional Project planning considerations including: overview of the proposed tolling framework, cost estimates for construction and operations, and business case for the Project.
- A summary of social, economic and environmental benefits that will result from the Project.

Project Proponent

The Project proponent is the B.C. Ministry of Transportation and Infrastructure, and if the Project is approved, an Environmental Assessment Certificate (EAC) will be awarded to and held by the Ministry. The Ministry plans transportation networks, provides transportation services and infrastructure, develops and implements transportation policies, and administers related acts and regulations. The Ministry opens up B.C. through innovative, forward-thinking strategies that move people and goods safely, and fuel the provincial economy. Improvement of vital infrastructure is a key goal, along with enhancing the competitiveness of B.C.'s transportation industries, reducing transportation-related greenhouse gas emissions and providing B.C. with a safe and reliable highway system.

Name of Proponent: B.C. Ministry of Transportation and Infrastructure

Primary Contact: Geoff Freer

Title: Executive Project Director

Address: 2030 – 11662 Steveston Highway
Richmond, B.C. V7A 1N6

Telephone: 1-855-562-7739

Email: masseytunnel@gov.bc.ca

Project Website: <https://engage.gov.bc.ca/masseytunnel/>

An environmental assessment team developed this Application for an EAC under the B.C. *Environmental Assessment Act*, led by the following team members:

- Malcolm Smith, Environmental Director
- Bindu Chembrakkalathil, Environmental Assessment Manager

Technical information within this Application has been developed with the input of discipline leads with expertise in relevant disciplines as summarized in **Table 1-1**.

Table 1-1 Environmental Assessment Discipline Leads

| Application Section Number | Responsible Team Member and Qualifications | Role on Project/Area of Technical Expertise |
|--------------------------------------|---|--|
| 2.0, 11.0 | Pamela Ryan, B.Com. (TLOG) | Communications and Public Consultation |
| 4.1 | Matt Gellis, P.Eng. | River Hydrology and Morphology |
| 4.2, 7.1 | Doug Bright, Ph.D., R.P.Bio., P.Biol. | Human Health and Water Quality and Sediment |
| 4.3 | Alex MacGillivray, M.Sc. | Underwater Noise |
| 4.4 | Jim Roberts, R.P.Bio. | Fish and Aquatics |
| 4.5 | Jared Hobbs, M.Sc., R.P.Bio. | At Risk Amphibians |
| 4.6 | Sonya Meier, M.Sc., R.P.Bio. | Marine Mammals |
| 4.7, 4.8 | Charlie Palmer, M.Sc., P.Biol., R.P.Bio. | Vegetation and Wildlife |
| 4.9 | Alex Schutte, B.Sc. | Air Quality |
| 4.10 | Clair Wakefield, M.A.Sc., P. Eng. | Atmospheric Noise |
| 5.1 | Neil Valsangkar, M.Sc., P. Eng. | Traffic |
| 5.2 | Joost Meyboom, Dr.sc.tech., P.Eng. | Marine Use |
| 5.3 | Ruth Hardy, M.Sc., P.Ag. | Land Use |
| 5.4 | Hugh Hamilton, Ph.D., P.Ag. | Agriculture |

| 7.0 | Doug Bright, PhD, R.P.Bio., P. Biol. | Health |
| 10.1.2 | Jemma Scoble, M.A.Sc. | Aboriginal Consultation |
| 10.1 (except 10.1.2) 10.2 10.3 | Monica Karpiak, M.A., RPCA | Traditional Use/Aboriginal Interests |

1.1 Description of Proposed Project

1.1.1 Project Purpose

Located on the Highway 99 corridor, the Tunnel is an important link in the regional and provincial transportation system, carrying an average of 80,000 vehicles each day. It is a vital people and goods movement route that fuels our national, provincial, and regional economies and a key access point for businesses in City of Richmond (Richmond), City of Surrey (Surrey), Corporation of Delta (Delta), and Tsawwassen First Nation.

The Tunnel provides an essential link between the municipalities of Delta and Richmond, and connects to key gateways such as Vancouver International Airport (YVR), Peace Arch and Pacific Canada-U.S. border crossings, BC Ferries Tsawwassen terminal, Deltaport, and Boundary Bay Airport.

Figure 1.1-1 provides an overview of the general Project alignment within the Lower Mainland. **Figure 10.1-1** in **Section 10** presents a summary of Halkomelem place names, in the vicinity of the Project.

George Massey Tunnel Replacement Project – PART A
 OVERVIEW OF PROPOSED PROJECT PROPONENT DESCRIPTION

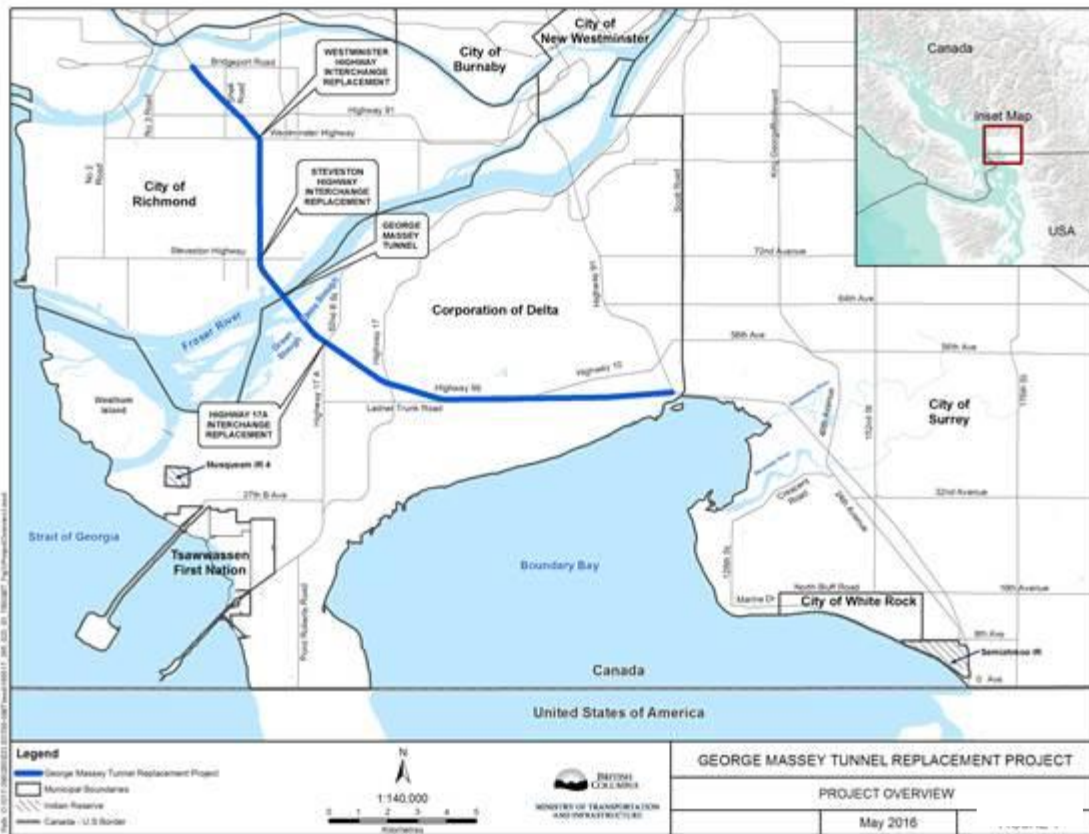

Figure 1.1-1 Project Context Map

Since the Tunnel opened in 1959, greater Vancouver’s population and economy have grown, and its population is forecast to continue to increase by more than one million people over the next 30 years. Without improvements to this crossing, economic growth and regional liveability will be constrained by congestion and increasing travel times for commuters, goods movers, commercial and other traffic.

With growing concerns about safety and traffic congestion in and near the Tunnel, in 2012 the Government of B.C. commenced a study of options to address these issues.

An extensive public and stakeholder consultation process in the fall of 2012 (Phase 1) and spring of 2013 (Phase 2) informed the development of six key Project goals:

- **Improve safety:** Improve traffic and seismic safety, as well as emergency-response capabilities.
- **Reduce congestion:** Improve travel times and reliability for all users.

- **Support trade and commerce:** Improve access to local businesses and gateway facilities and improve travel time reliability for goods movers and service providers.
- **Support increased transit on the Highway 99 corridor:** Provide dedicated transit/high-occupancy vehicle (HOV) lanes on the new bridge will improve travel time reliability and add capacity for long-term transit improvements.
- **Support options for pedestrians and cyclists:** Provide multi-use pathways on the new bridge to connect cycling and pedestrian corridors in Richmond and Delta.
- **Enhance the environment:** Enhance the environment under the new bridge and in the Project right-of-way (ROW) on Deas Island.

Based on the Ministry's mandate, technical analysis and results of consultations, a new bridge to replace the Tunnel emerged as the preferred solution, and in September 2013, was carried forward for development.

The Project is strategically important not only to assist in fulfilling the Ministry's mandate, but also to support the mandates and objectives of many other transportation agencies. These include local, regional and national/international bodies with responsibilities in transit, air, marine, rail, road and inter-modal operations, with respect to both passenger traffic and goods movement.

The Project has been developed in consideration of national, provincial, regional and local economic, transportation and land use plans, including the following:

National Plans

- Asia-Pacific Gateway and Corridor Initiative (2006)
- Building Canada plan (2007)
- Economic Action Plan (2014)
- Port 2050 (2010) Port Metro Vancouver's Land Use Plan Update (2014)

Provincial Plans

- Pacific Gateway Transportation Strategy (2012–2020)
- BC Jobs Plan (2011)
- B.C. on the Move: A 10-Year Transportation Plan, Government of British Columbia, 2015

Regional Plans

- Metro Vancouver's Regional Growth Strategy(2011)

- TransLink's Regional Transportation Strategy (2013)
- Corporation of Delta's Official Community Plan (2012)
- City of Richmond's Official Community Plan (2012)
- City of Surrey's Official Community Plan (2013)
- City of White Rock's Official Community Plan (2008)
- Tsawwassen First Nation's Land Use Plan (2009)

1.1.2 Project Development History

The need for added capacity at the George Massey Tunnel crossing has been identified a number of times over past decades and numerous technical and planning studies that have informed the development of the proposed Project have been undertaken during this period. The purpose of this section is to provide an overview of recent, as well as historic technical and planning work that has been considered in the development of the proposed Project. All of the documents noted below, plus an extensive list of additional technical and planning documents, can be found at www.masseytunnel.ca.

As early as 1989, the Freedom to Move plan developed by the Greater Vancouver Transportation Task Force (1989) recommended that the Tunnel be expanded by 2001 in order to address congestion issues and improve the regional transportation network. Building on this, in 1991 the Ministry of Transportation commissioned the George Massey Tunnel Expansion Planning Study (Ward Consulting Group 1991) which explored five options and recommended new tunnel capacity at the existing crossing for the short term, and a new 72nd Street/No. 8 Road crossing for the long term.

In 1993, A Long-Range Transportation Plan for Greater Vancouver: Transport 2021 Report (Greater Vancouver Regional District 1993) that was developed in support of developing the Livable Region Strategic Plan (Greater Vancouver Regional District 1999), identified the need for additional capacity across the north and south arms of the Fraser River. Following the Transport 2021 report, in 1995 the Ministry of Transportation commissioned the Fraser River North and South Arm Crossing Study (Reid Crowther and Partners Ltd. and Ward Consulting Group 1995) which considered 12 options including expanding the Oak Street Bridge to five lanes, adding a new tube at the existing George Massey Tunnel, upgrading Highway 99 between Highway 17 and the Oak Street Bridge, and constructing a new crossing at Tree Island between Highway 91 in Richmond and Marine Way in Burnaby.

The various concepts presented in both the 1991 and 1995 studies, in addition to technical work to address seismic challenges associated with the Tunnel and studies supporting rapid bus and

HOV improvements on the Highway 99 corridor between 2008 and 2011, informed the development of the conceptual design presented in **Section 16.1 Reference Concept**.

In its provincial transportation strategy, “B.C. on the Move” (March 2015), the Ministry has confirmed the Project as a Priority for Action to improve highway safety, capacity and reliability – addressing one of the region’s worst congestion points.

In the context of recent work to support the planning of the George Massey Tunnel Replacement Project, a range of technical and planning studies were conducted between 2012 and 2015. These studies cover a range of areas and disciplines including geotechnical, costing, project risk, procurement and traffic studies. Summaries of key studies undertaken are provided below.

1.1.2.1 Traffic Studies

George Massey Tunnel Replacement Project Analysis of OD Survey Data

This report documents the methodology and findings of the Origin-Destination (OD) surveys conducted in October and November, 2013 (Delcan 2015a).

George Massey Tunnel Replacement Project Analysis of OD Survey Data Fall 2014

This report documents the methodology and findings of the OD surveys conducted in October and November, 2014 (Delcan 2015b).

George Massey Tunnel Replacement Project Collision Data Analysis

The purpose of this document is to outline the methodologies and assumptions used in the analysis, and present the findings (Delcan 2015c).

George Massey Tunnel Replacement Project Traffic Data Collection Report Fall 2014

This report summarizes data collected during October of 2014. The report builds on and complements initial data collection activities that were conducted during the summer and fall of 2013, spring of 2014, and summer of 2014 (B.C. MOTI 2015a).

George Massey Tunnel Replacement Project Traffic Data Collection Report Spring 2014

This report documents the traffic data collected in April, 2014 on Highways 99, 91, 17, 17A and 10. The information includes: vehicle count data (from permanent count stations; short count stations; manual counts; and, tube counts); vehicle occupancy survey data; and, corridor travel times. The report builds on the initial data collection activities that were conducted during fall and summer 2013 (B.C. MOTI 2015b).

George Massey Tunnel Replacement Project Traffic Data Collection Report Summer 2014

This report documents the traffic data collected in August, 2014 on Highways 99, 91, 17, 17A and 10. The information includes: vehicle count data (from permanent count stations; short count stations; manual counts; and, tube counts); vehicle queue observations; and, corridor travel times. The report builds on initial data collection activities that were conducted during the summer fall of 2013 and spring of 2014 (B.C. MOTI 2015c).

George Massey Tunnel Replacement Project Traffic Data Collection Report Summer & Fall 2013

This report documents the traffic surveys completed and vehicle count data collected in August, October and November, 2013 on Highways 99, 91, 17, and 10. The information includes: traffic count data (from permanent count stations; short count stations; manual counts; signal controllers; and, tube counts); origin-destination survey data; vehicle queue observations; vehicle occupancy survey data; corridor travel times; transit ridership survey data; bike shuttle counts; and collision data. The purpose of this report is to document the planning and assumptions involved with each traffic data collection activity and consolidate and organize the data collected by the traffic data collection program (B.C. MOTI 2015d).

George Massey Tunnel Replacement Project Traffic Data Overview

The purpose of this report is to provide an overview of the traffic information collected and the assessment undertaken to support the development of the George Massey Tunnel Replacement Project. It also serves as a technical reference document through the inclusion of appendices with facts, figures, and records of source documentation (B.C. MOTI 2015e).

1.1.2.2 Planning Studies

George Massey Tunnel Replacement Project Business Case

This study establishes the need for improvements and how the Project will contribute to the objectives and strategies to improve transportation infrastructure in Metro Vancouver (B.C. MOTI 2015f).

Capital Cost Estimate Report George Massey Tunnel Replacement Project

This report details the conceptual capital cost estimate for the Project, including design & construction, bid development, owner's costs, IDC, contingency, and risk (B.C. MOTI 2015g).

Massey Tunnel Financial Model

This report summarizes inputs to the financial modelling for value for money comparison of the Design Build and Design Build Finance Operate Maintain Rehabilitate delivery models (B.C. MOTI 2015h).

Operations, Maintenance and Rehabilitation Base Cost Estimate Report George Massey Tunnel Replacement Project

This report provides an assessment of costs for operational maintenance and rehabilitation services anticipated over both the operating term and service life including assumptions relating to: service life, tolling operations, inflation and contingency (B.C. MOTI 2015i).

Procurement Options Report George Massey Tunnel Replacement Project: Identification and Assessment of Procurement Options for Detailed Business Case Analysis

This analysis identifies procurement alternatives for the Project and narrows to two preferred options (a traditional Design Build and a Design Build Finance Operate Maintain Rehabilitate partnership model), for input to detailed analysis in the Business Case (B.C. MOTI 2015j).

George Massey Tunnel Replacement Project Risk Report

This report documents the risk assessment process for the Project including: overview of approach, risk identification and allocation between Province and Contractor, risk management strategies, assessment and quantification methodology for input to Business Case (B.C. MOTI 2015k).

George Massey Tunnel Replacement Project Evaluation of Crossing Scenarios

This report evaluates five potential crossing scenarios for the Project as identified in “Planning for the Future Phase 2: Exploring the Options Consultation Discussion Guide” (B.C. MOTI 2013). This report identifies “New Replacement Bridge on Highway 99 corridor” as the preferred solution (MMK Consulting Inc. 2014).

George Massey Tunnel Replacement Project Conceptual Highway and Interchange Design Summary Report

The purpose of this report is to document the basis for the conceptual designs of the five potential crossing scenarios, the assumptions made, the work completed and resulting findings, and any key actions required for future design development of the concepts (CH2M Hill Canada Limited 2014).

1.1.2.3 Geotechnical Studies

Basic Field Data Report George Massey Tunnel Replacement

This report presents the basic results of a geotechnical site investigation program conducted from January 15th to May 29th, 2014 at the George Massey Tunnel. The program consisted of 18 Cone Penetration Tests (CPT), 34 Seismic Cone Penetration Tests (SCPT), and one Downhole Seismic Test (DHS) (ConeTec Investigations Ltd. 2014a).

Downhole Seismic Field Data Report George Massey Tunnel Replacement Project

This document contains the test data for downhole seismic testing (ConeTec Investigations Ltd. 2014b).

Geotechnical Data Report George Massey Tunnel Replacement Project

This report documents the results of a geotechnical investigation carried out between November 2013 and January 2014, which included a site description, project description, geotechnical scope of work, review of available information, and results of a geotechnical investigation. The data collected from two boreholes drilled near the north and south tunnel portals (Golder Associates Ltd. 2014a).

Geotechnical Data Report - Highway 99 and Interchanges George Massey Tunnel Replacement Project

This report documents the results of the geotechnical investigation carried out along the existing Highway 99 corridor between Westminster Highway in Richmond and Highway 17A in Delta, BC, during January and February, 2015 (Golder Associates Ltd. 2015a).

Geotechnical Data Report - Steveston Highway Interchange and Green Slough George Massey Tunnel Replacement Project

This report documents the results of the geotechnical investigation carried out along the existing Highway 99 corridor between Steveston Highway in Richmond and River Road at Green Slough in Delta, BC, during September and October, 2015 (Golder Associates Ltd. 2015b).

Geotechnical Data Report - Test Pile Site George Massey Tunnel Replacement Project

This report presents the results of a geotechnical investigation and laboratory testing at the proposed test pile location adjacent to the existing south portal of the George Massey Tunnel on the east side of Highway 99 in January 2015 (Golder Associates Ltd. 2015c).

Supplemental Geotechnical Laboratory Testing George Massey Tunnel Replacement Project, Richmond & Delta, BC

This document provides the results of supplemental laboratory testing carried out on samples collected during geotechnical investigation, between November 2013 and January 2014 (report dated April 2014) (Golder Associates Ltd. 2014b).

1.1.3 Project Rationale

The following section provides an overview of the key drivers that support the rationale for the Project, including: importance of the Tunnel in the regional transportation network, historic trends in population and traffic growth on the Highway 99 corridor, current conditions including congestion, future regional growth in population and traffic demand, and public support that has been identified through Project consultation and engagement.

1.1.3.1 Importance of the Tunnel

The Tunnel provides the main road connection between the municipalities of Delta and Richmond, and Highway 99 is the primary travel route between Delta, Surrey, White Rock, and Tsawwassen First Nation to the south, and Richmond and Vancouver to the north. In its current configuration, the Tunnel serves a wide range of users, including auto and transit commuters and other local traffic, light and heavy commercial truck traffic, travellers to and from the U.S., and other visitors to the region.

Highway 99 and the Tunnel serve as a key link to several major international transportation gateways, including the Deltaport container terminal at Roberts Bank, Vancouver International Airport (YVR), and the Pacific Highway and Douglas (Peace Arch) Canada-U.S. border crossings leading to and from the U.S. interstate highway system. The Tunnel also provides a key connection to BC Ferries services between Tsawwassen, Vancouver Island and the Southern Gulf Islands, and a highway link to Boundary Bay Regional Airport.

1.1.3.2 Historic Population and Traffic Trends

Highway 99 communities adjacent to the Tunnel have experienced strong population growth for decades. As illustrated in **Figure 1.1-2** below, the combined population of Richmond, Surrey, Delta, and White Rock doubled between 1986 and 2011, from 400,000 to 800,000.

Figure 1.1-2 Historic Census Population of Highway 99 Corridor Communities (Statistics Canada 2016)

To help serve greater Vancouver's growing population, the six-lane Alex Fraser Bridge opened upstream from the Tunnel in 1986. This bridge and the Highway 91 corridor have provided a similar-distance alternate route for the significant portion of traffic travelling between South Surrey/White Rock and much of Vancouver, Burnaby, and Richmond.

The opening of the Alex Fraser Bridge initially led to some congestion relief at the Tunnel; however, traffic levels at the Tunnel continued to grow with population and employment, reaching a daily average of 80,000 vehicles by the early 1990s, resulting in major morning and afternoon congestion periods in both directions.

From the early 1990s to the early 2010s, the Alex Fraser Bridge absorbed virtually all of the growth in Richmond and Delta cross-river traffic realizing steadily increased volumes while volume trends at the Tunnel generally remained flat. For the two crossings combined, the average traffic growth rate between 2003 and 2013 was 0.64 % per year. **Figure 1.1-3** presents historic annual average daily traffic volumes from 1989 to 2013.

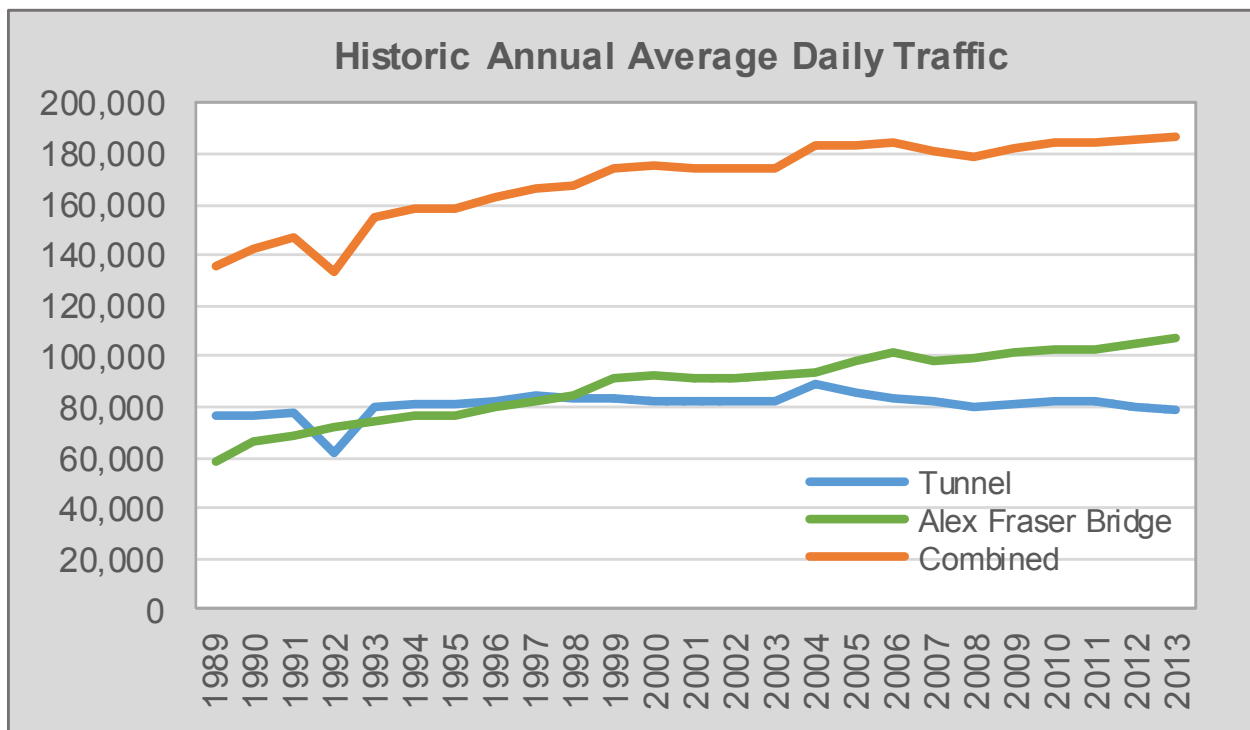

Figure 1.1-3 Historic Annual Average Daily Traffic (B.C. MOTI 2015a)

1.1.3.3 Current Congestion Patterns at the Tunnel and at the Alex Fraser Bridge

During the morning and afternoon rush periods, drivers using the Tunnel experience substantial congestion in both directions. For the three lanes of northbound morning and southbound afternoon traffic, the average peak delay time is eight minutes northbound in the morning, in addition to eight minutes southbound in the afternoon, for a daily total of 16 minutes. For the single lane of counter flow traffic, peak traffic delay times are even higher: eight minutes

southbound in the morning, in addition to 18 minutes northbound in the afternoon, for a daily total of 26 minutes. When there is a crash or vehicle breakdown, these queues, and resulting delay times, can be much longer.

Traffic volumes also approach capacity during regular two-lane operations on weekdays and on weekends, where even a minor traffic incident can lead to substantial congestion delays. Holiday weekends are particularly congested, with highly variable and unpredictable travel times.

With the Alex Fraser Bridge absorbing most of the demand, its traffic levels have grown substantially over the past two decades. This bridge is now at capacity in rush hour, with limited ability to accommodate additional traffic volumes. Congestion delays for morning northbound and afternoon southbound traffic are now greater at Alex Fraser Bridge than at the Tunnel, especially for morning northbound traffic.

The following two graphs (Figure 1.1-4 and Figure 1.1-5) illustrate northbound and southbound weekday congestion patterns, by time of day, at the Tunnel and the Alex Fraser Bridge.

Section 5.1 Traffic provides a detailed description of current and future traffic conditions in the Project area.

Figure 1.1-4 Northbound Highway 99 and Highway 91 Traffic Delay Time (2013) (B.C. MOTI 2016)

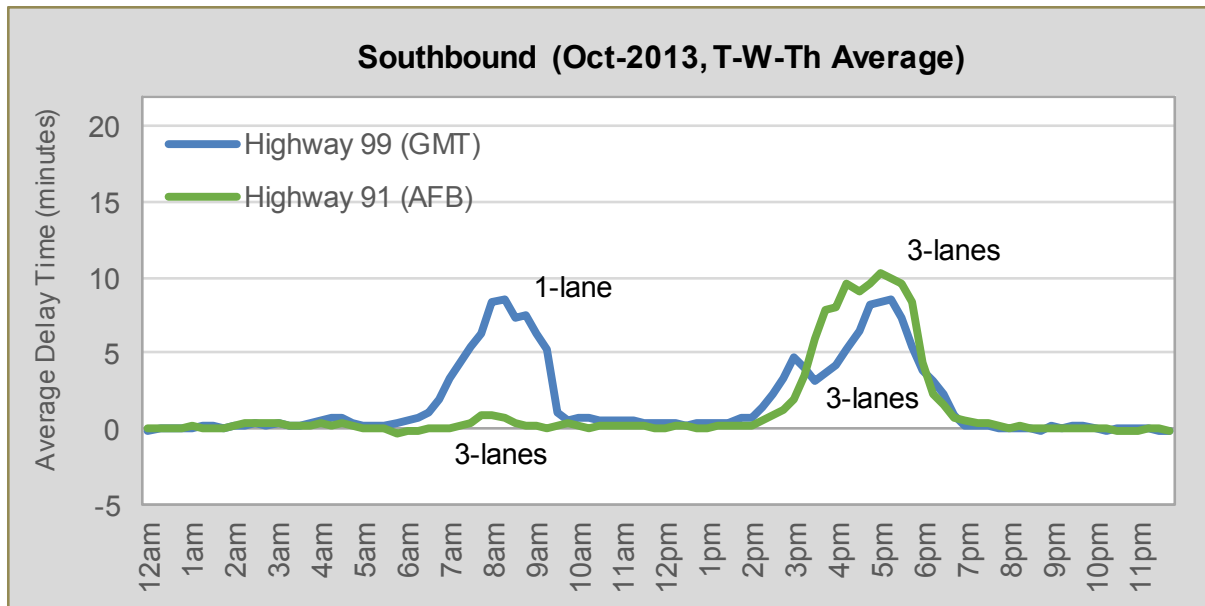

Figure 1.1-5 Southbound Highway 99 and Highway 91 Traffic Delay Time (2013) (B.C. MOTI 2016)

Future increases in cross-river traffic volumes are forecast at both the Tunnel and the Alex Fraser Bridge, and will result in increasing congestion at both locations. As with current conditions within the corridor, the nature of such congestion is variable and unpredictable throughout the day.

1.1.3.4 Future Growth in Population and Traffic Volumes

The Greater Vancouver Regional District (Metro Vancouver) regional growth strategy *Metro 2040: Shaping our Future (Metro 2040)* projects an increase of more than 60 per cent from 2006 numbers in population and employment in Richmond, Surrey, and Delta by 2041, representing an average annual growth rate of more than 1.4 per cent per year (Metro Vancouver 2015).

With respect to future traffic volumes, forecasts based on TransLink’s Regional Transportation Model (RTM) (2013) predict that under continued Tunnel operation, daily traffic volumes at the Tunnel will increase from 79,000 to 97,000 between 2013 and 2045, which represents an average growth rate of 0.64 per cent per year. This forecast traffic growth rate, while less than half of the projected population growth rate, is consistent with the actual growth in combined Tunnel and Alex Fraser Bridge traffic between 2003 and 2013 (see **Table 1.1-1** below).

Table 1.1-1 Projected Population, Employment, and Traffic Growth

| Projected Growth | Recent Census Year | Target Year | Average Annual Growth |
|--|--------------------|-------------|-----------------------|
| Population and Employment ¹ | 2006 | 2041 | |
| Population | 714,400 | 1,203,000 | 1.50% |
| Employment | 335,240 | 558,800 | 1.47% |
| George Massey Traffic Growth | 2013 | 2045 | |
| Annual Average Daily Traffic (AADT) ² | 79,000 | 97,000 | 0.64% |

Note: ¹ For Richmond, Delta, Tsawwassen, Surrey, and White Rock.

² Source: Metro Vancouver's Regional Growth Strategy (2015)

1.1.3.5 Future Travel Time Delays under Continued Tunnel Operation

As indicated in **Figure 1.1-4** and **Figure 1.1-5** above, one-way travel time delays averaging eight to 18 minutes are routinely experienced in both directions, during both the morning and afternoon peak periods. Peak period round-trips delay times are currently 16 to 26 minutes, depending on direction.

Looking ahead, given the current high levels of congestion at the Tunnel, even the RTM-predicted moderate annual traffic growth rate will result in significant increases in future congestion levels.

Based on a detailed analysis of current and forecast traffic patterns, and assuming 0.6 per cent average annual traffic growth, round-trip delay times for peak-period travellers under continued Tunnel operation are forecast to increase to between 27 to 39 minutes (depending on direction) in 2021, and 99 to 105 minutes in 2045 (**Table 1.1-2**).

Table 1.1-2 Current and Future Weekday Congestion Delays under Continued Tunnel Operation

| Traffic Direction | Weekday Congestion Delays | | |
|---------------------------------|---------------------------|---------|----------|
| | 2013 | 2021 | 2045 |
| Peak direction delays (3 lanes) | | | |
| Northbound AM weekdays | 8 min. | 11 min. | 32 min. |
| Southbound PM weekdays | 8 min. | 16 min. | 67 min. |
| Combined | 16 min. | 27 min. | 99 min. |
| Counterflow delays (1 lane) | | | |
| Southbound AM weekdays | 8 min. | 16 min. | 41 min. |
| Northbound PM weekdays | 18 min. | 23 min. | 64 min. |
| Combined | 26 min. | 39 min. | 105 min. |

1.1.3.6 Public Support for Replacing the Existing Tunnel

The Ministry's public consultation programs in 2012 and 2013 (**Section 11 Public Consultation**) confirmed strong support for relieving traffic congestion with a new bridge on the existing Highway 99 corridor as soon as possible.

Further details on the rationale for the Project, and the strong levels of public support for it, are contained in the results of public consultation programs, and Project Definition Report (B.C. MOTI 2015a), as posted on the George Massey Tunnel Replacement Project website at www.masseytunnel.ca.

1.1.3.7 Tunnel Decommissioning

When the new bridge is open to traffic, the Tunnel will be decommissioned and the four in-stream segments removed to:

- Eliminate future risk of damage to the new bridge and impact to shipping associated with significant seismic activity;
- Meet Ministry best practice regarding management of obsolete infrastructure; and,
- Provide opportunities to restore important Fraser River habitat.

Removing the in-stream segments of the Tunnel addresses the risks that an earthquake may cause the Tunnel to shift, creating an obstruction in the shipping channel and/or damaging the Fraser River shoreline. Given the importance of the Fraser River as a transportation corridor that supports the national and provincial economies and as a diverse marine ecosystem, the impact of such an occurrence would be significant. As such, leaving the in-stream segments in place presents a long-term liability to the Province.

Removing in-stream Tunnel elements concurrent with the Project also represents the least cost alternative – it would be significantly more expensive and risky to undertake this work at some later date in the future, should it be deemed necessary.

Additionally, obsolete infrastructure degrades over time, so it is standard practice to remove redundant facilities and man-made materials when new infrastructure replaces it. Removing the in-stream segments of the Tunnel will return the river bottom to its natural condition. This also provides the opportunity to backfill the south portal, reconnect the two sides of Deas Island that are currently bisected by the Highway 99 roadway, and re-establish riparian habitat in this area.

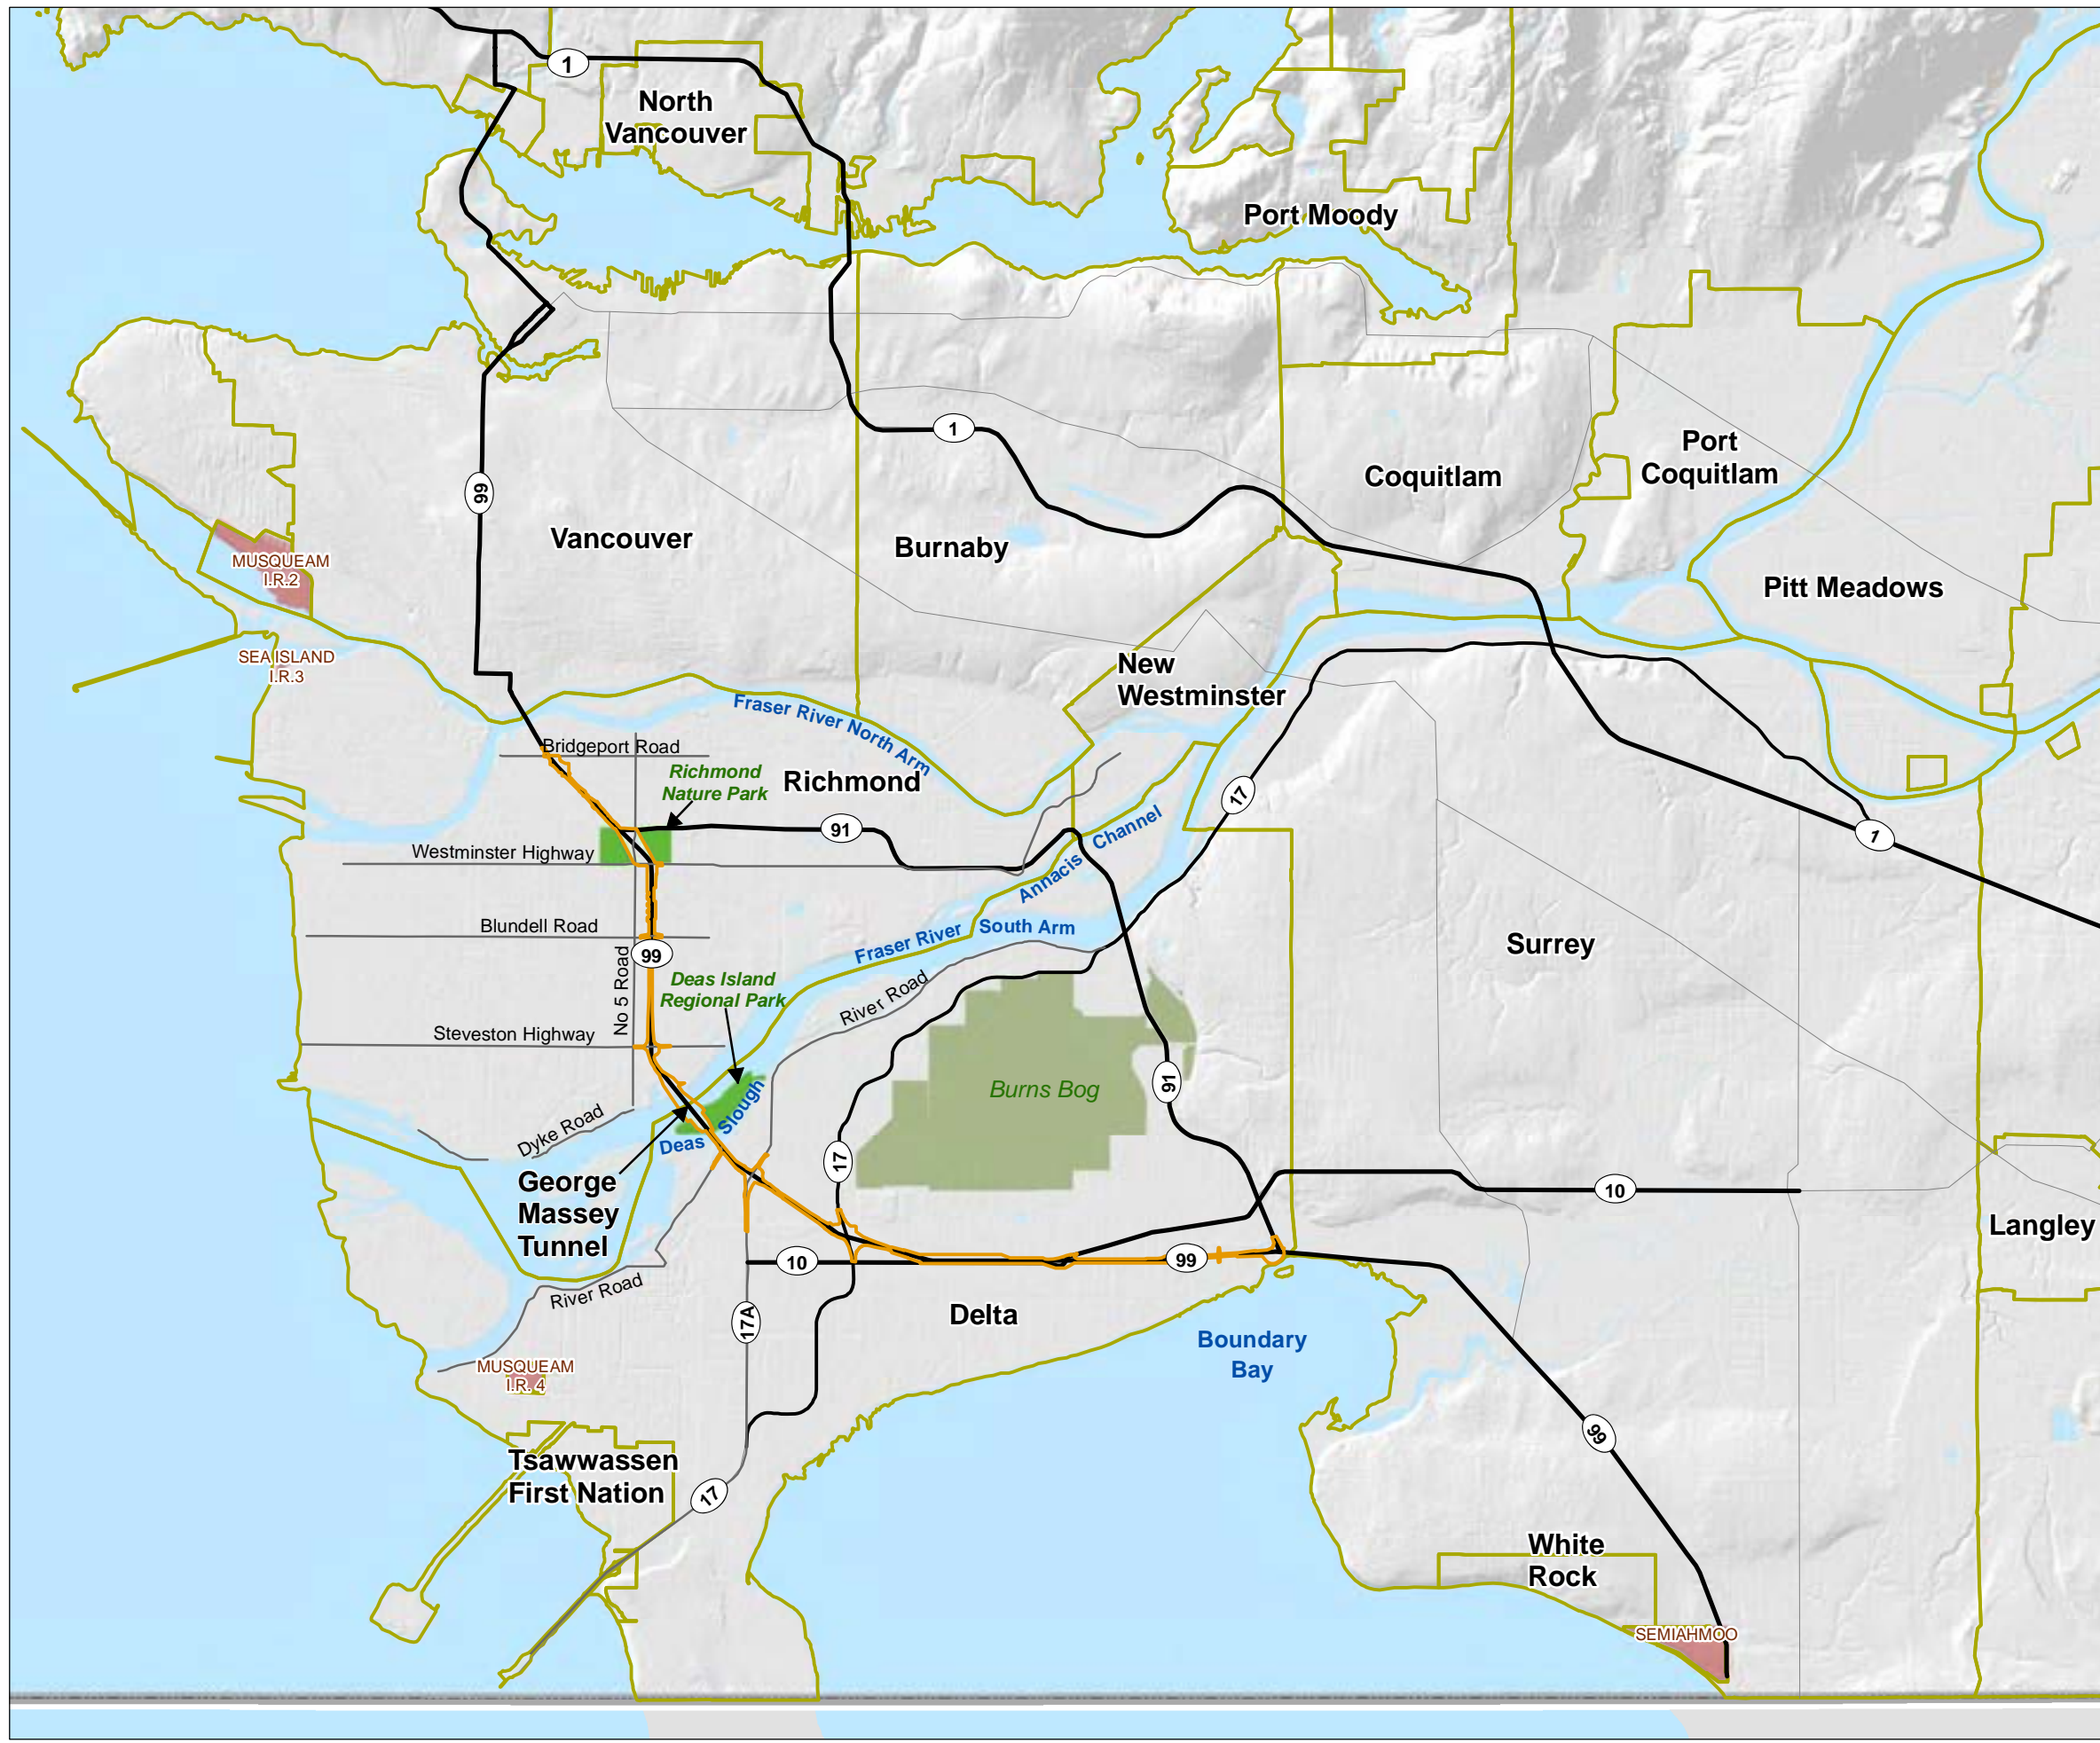

1.1.4 Project Location

The Project is located within the Highway 99 corridor in B.C.'s lower mainland (49° 07'18.36" N and 123° 04'32.32" W) (**Figure 1.1-6**).

The northern extent of the Project is the Bridgeport Road interchange in Richmond. The Project alignment then continues south along the Highway 99 corridor to the new bridge crossing over the Fraser River South Arm. South of the new bridge, the Project continues along the Highway 99 corridor to the Highway 91 interchange in Delta. Federal land in proximity to the Project alignment includes the following:

- Sea Island Indian Reserve No. 3, approximately two kilometres west of the Project .
- Musqueam Indian Reserve No. 4, approximately five kilometres northwest of the Project.
- Semiahmoo Indian Reserve, approximately 12 kilometres southeast of the Project .
- Alaksen National Wildlife Area and George C. Reifel Migratory Bird Sanctuary, which overlaps the Alaksen National Wildlife Area, located approximately seven kilometres west of the Project.
- Department of National Defense, less than one kilometre from the Project.
- Fraser Wharves, managed by the VFPA, is located adjacent to the Project.
- Submerged land in the Fraser River North and Middle Arms, the portion of submerged land under the Fraser River west of Tilbury Island and several parcels of foreshore and upland areas in Richmond and Delta.

REPLACEMENT PROJECT**

PROJECT LOCATION

| | |
|--------------|------------|
| Figure 1.1-6 | 13/05/2016 |
|--------------|------------|

1.1.4.1 Adjacent Land Use

Land use in areas adjacent to the Highway 99 corridor in Richmond and Delta, in the Newton Area of Surrey, and in the far west and far east portions of Highway 99 through South Surrey is predominantly agricultural. Most of the agricultural land adjacent to the highway falls within the provincial Agricultural Land Reserve.

Along the Project alignment, Highway 99 provides access to, and supports the following:

- Agricultural lands.
- Municipal properties used for local and regional transportation, public services, and educational institutions.
- Parks and recreation.
- Single- and multi-unit residences.
- Religious institutions.
- Retail and commercial/industrial (light and heavy) facilities.

The new bridge will span the Fraser River South Arm and Deas Slough, which are used for commercial, recreational and Aboriginal fishing, port activities, and commercial and recreational marine purposes.

Deas Island Regional Park, located on either side of the Project alignment along the south approach to the Tunnel, provides recreational opportunities including walking trails, picnic areas, and access to recreational boating along Deas Slough.

The Tsawwassen First Nation is located approximately six kilometres southwest of the Project alignment, adjacent to Roberts Bank, between the BC Ferries Tsawwassen Terminal and Deltaport.

1.1.4.2 Land Ownership and Management

The Project is generally within Ministry ROW, including land that is under water, with Vancouver Fraser Port Authority (VFPA) having navigational jurisdiction in the Fraser River. Metro Vancouver owns Deas Island Regional Park, located immediately outside the Project alignment on Deas Island.

The following legislation apply to the use and management of lands within the Project alignment:

- *Canada Marine Act*, S.C. 1998, c. 10, which establishes VFPA's navigation jurisdiction within the Fraser River.
- B.C. *Land Act*, R.S.B.C. 1996, c. 245, which governs the disposition of provincial Crown land.
- *B.C. Agricultural Land Commission Act*, S.B.C. 2002, c. 36, which establishes the provincial Agricultural Land Reserve (ALR) and permitted uses within the ALR
- B.C. Community Charter and *Local Government Act*, R.S.B.C. 1996, c. 323, which establishes the authority for local government planning bylaws
- B.C. *Wildlife Act*, R.S.B.C. 1996, c. 488, which establishes Wildlife Management Areas (WMAs) for conservation purposes

Land use interactions and potential effects on land use are discussed in **Section 5.3** of the Application. The Project is sited largely on provincial Crown land within Richmond and Delta, and straddling the Fraser River South Arm. The majority of the proposed works are located within the highway ROW; however, small portions of land in Delta and Richmond adjacent to the ROW will be required for the Project. Land Ownership is described in more detail in **Section 5.3 Land Use** and shown on **Figure 5.3-3**.

Land within Richmond, Delta, and Surrey is owned by federal, provincial, or local governments; First Nations; or is privately held. The federal government owns the submerged land in the Fraser River North and Middle Arms, the portion of submerged land under the Fraser River west of Tilbury Island, and several parcels of foreshore and upland areas in Richmond and Delta. The Province owns submerged land in the Fraser River South Arm east of Tilbury Island, and the submerged land within the Project alignment. The Province manages tenures for uses within this area. Outside of the Highway 99 ROW, the Province owns some upland parcels and submerged lands adjacent to the Project alignment. Metro Vancouver owns Deas Island Regional Park, which is situated on both sides of the south approach to the Tunnel. Richmond owns three parcels and Delta owns several parcels adjacent to the ROW.

Provincial land holdings within the vicinity of the Project include the BC Ferries fleet maintenance facility (Deas Pacific Marine) in south Richmond, portions of the South Arm Marshes Wildlife Management Area (WMA), and smaller parcels in upland areas of Delta. Ownership of the Burns Bog Ecological Conservancy Area is shared between the Province and a partnership between Metro Vancouver and Delta. The City of Vancouver owns the Vancouver Landfill, situated between Highway 99 and the southwest corner of Burns Bog. Delta owns the

land base for the Boundary Bay Airport, and several parks and recreational corridors. Richmond and Delta own the land base for their respective arterial and local roads, community centres, and public works facilities. The remainder of land, which includes a Canadian National (CN) rail corridor in Richmond and a Burlington Northern Santa Fe rail corridor in Delta, is privately owned.

Tsawwassen First Nation Lands, as defined by the *Tsawwassen First Nation Final Agreement* (2009), are located approximately six kilometres southwest of the Project alignment, adjacent to Roberts Bank. Musqueam Indian Reserve No. 4 is located approximately five kilometres northwest of the Project alignment. Information on First Nation Treaty lands and Indian Reserves is provided in **Section 10 Aboriginal Consultation**.

Support structures for the new bridge will be installed on Deas Island and adjacent to Deas Slough within the Highway 99 corridor, outside of Deas Island Regional Park and the main channel of the south arm of the Fraser River. In Richmond, just south of Rice Mill Road, Highway 99 crosses the CN rail line, which is private land. The Project does not overlap federal lands, First Nation Reserves, or federal or provincial parks or Protected Areas.

1.1.4.3 Asserted Traditional Territories and Treaty Nation Territories

As shown in **Figure 1.1-7**, the Project is entirely or partially located within the following Aboriginal Groups' asserted traditional territories, and/or Treaty Nation territories:

- Cowichan Tribes
- Halalt First Nation
- Katzie First Nation
- Kwantlen First Nation
- Lake Cowichan First Nation
- Lyackson First Nation
- Musqueam Indian Band
- People of the River Referrals Office

- Penelakut Tribe
 - Hwlitsum¹
- Semiahmoo First Nation
- Stz'uminus First Nation
- Squamish Nation
- Tsawwassen First Nation
- Tsleil-Waututh Nation

Further detail on the location of the Project in relation to traditional territories and Treaty Nation territories is provided in **Section 10.0 Aboriginal Consultation**.

¹ This reference to the Hwlitsum is not intended to signify any change in the position that the Province may have taken in other contexts in relation to the duty to consult with this group.

1.1.5 Project Phases and Schedule

The Ministry developed the draft conceptual design for the Project between 2013 and 2015. If an EAC is awarded for the Project, the Ministry intends to start Project construction in 2017, with the new bridge opening in 2022, followed by Tunnel decommissioning.

Major elements of the Project schedule are shown in **Table 1.1-3**. A description of Project activities during the site preparation, construction, and operation and maintenance phases of the Project is provided in **Section 1.1.8**.

The Project is intended as a permanent component of the regional and provincial transportation system, with a 100-year service life for the new bridge. There are no plans to decommission any new Project components in the foreseeable future.

Table 1.1-3 Project Schedule from Draft Conceptual Design to Completion

| Project Phase and Stage | Proposed Schedule |
|--|---|
| Pre-Construction and Site Preparation | |
| EAC Application and Regulatory Review | 2016 |
| Anticipated EA certification | Early 2017 |
| Procurement | 2016 – 2017 |
| Site Preparation | 2017 |
| Construction | |
| Construction of Project components | 2017 – 2022 |
| Tunnel decommissioning | Following opening of the new bridge in 2022 |
| Operation | |
| Operation and Maintenance | Ongoing from 2022 |

1.1.6 Key Project Components

The Project involves constructing a clear span bridge over the Fraser River, highway improvements along Highway 99 from Bridgeport Road in Richmond to Highway 91 in Delta, including improved drainage infrastructure and overpass replacements, replacing three interchanges, incorporating new transit and HOV facilities, providing connections to the municipal cycling/pedestrian path network and decommissioning the Tunnel.

Once commissioned, the Project will become part of the provincial highway system. The Ministry will select a contractor to provide products and services associated with the management, planning, and delivery of construction, operation, maintenance, and rehabilitation activities in accordance with defined Performance Measures.

The Project scope, divided into four sections, is detailed in the Reference Concept included in **Section 16.1**, drawings EA-H-1001 to EA-H-1015, and summarized below.

Section 1 – Bridgeport Road to Westminster Highway

- Construct a dedicated transit road under the Oak Street Bridge between Van Horne Way and Bridgeport Road.
- Provide a dedicated transit connection between Bridgeport Road and Highway 99 along Bridgeport Road and Sea Island Way, connecting to the transit/HOV lanes on Highway 99.
- Match to existing Highway 99 laning at the south abutment of the Oak Street Bridge.
- Construct two new median transit/HOV lanes between Bridgeport Road and Westminster Highway including replacing Cambie Road underpass Shell Road overpass and the Highway 91 westbound to Highway 99 southbound ramp bridge.
- Construct a median barrier on Highway 99 for traffic safety and to support mid-island flood protection in the City of Richmond.
- Improve drainage along Highway 99 including provisions to manage water flow rates, water levels and water quality.
- Replace the Westminster Highway interchange to accommodate all existing connections and improve cyclist/pedestrian connectivity across Highway 99.

Section 2 – Westminster Highway to Steveston Highway

- Widen Highway 99 to allow for two new dedicated median transit/HOV lanes and four general purpose lanes in each direction between Westminster Highway and Steveston Highway including replacing the Blundell Road underpass.
- Upgrade the median barrier on Highway 99 for traffic safety and to support mid-island flood protection in the City of Richmond.
- Improve drainage along Highway 99 including provisions to manage water flow rates, water levels and water quality.
- Replace the Steveston Highway interchange to accommodate all existing traffic movements and provide a new direct connection between Rice Mill Road and Highway 99 to help alleviate congestion at the Steveston Highway/No. 5 Road intersection.

- Provide an integrated median transit/HOV lane transit stop in the Steveston Interchange with connections to bus service on Steveston Highway including safe and convenient walkways, stairs and elevators for pedestrians and cyclists to access the transit stops.
- Provide multi-use pathways at the Steveston Highway interchange for east-west access across Highway 99, north-south access to Rice Mill Road and access to the multi-use pathways on the new bridge.

Section 3 – Steveston Highway to Highway 17A

- Widen Highway 99 to allow for two new dedicated median transit/HOV lanes and four general purpose lanes in each direction between Steveston Highway and Highway 17A.
- Construct a new 10-lane bridge with a clear span over the Fraser River and multi-use pathways for cyclists and pedestrians. The new bridge will be built to accommodate potential future rapid transit and will provide navigational clearances similar to those at the Alex Fraser Bridge.
- Provide connections between the multi-use pathways on the new bridge to Steveston Highway, River Road South and the Millennium Trail.
- Replace the Deas Slough Bridge with the Delta approach to the new bridge. The Delta approach will be significantly higher than the Deas Slough Bridge allowing a wider range of boats to pass underneath.
- Construct a southbound ramp exit for the new bridge connecting to River Road South.
- Provide sufficient clearance at River Road to allow the Corporation of Delta to extend River Road South eastward, improving connectivity between Ladner and North Delta.
- Replace the Highway 17A interchange to accommodate all existing traffic movements.
- Provide an integrated median transit/HOV lane transit stop in the Highway 17A interchange with connections to bus service on Highway 17A including safe and convenient walkways, stairs and elevators for pedestrians and cyclists to access the transit stops.
- Provide multi-use pathways at the Highway 17A Interchange for east-west access across Highway 99 and a connection to the shoulders of Highway 17A and Vassey Road.
- Provide biofiltration ponds to manage stormwater runoff from the road.
- Decommission the Tunnel.

Section 4 – Highway 17A to Highway 91

- Widen Highway 99 to allow for two new dedicated median transit/HOV lanes and additional general purpose lanes between Highway 17A and Highway 91 including replacement of the Matthews underpass at Ladner Trunk Road/Highway 10, and 112th Street underpass.
- Improve drainage along Highway 99 including provisions to manage water flow rates, water levels and water quality.
- Match to the existing cross section of Highway 99 just west of the Highway 91 interchange.

1.1.7 Project Design Considerations

1.1.7.1 General Design Considerations

The following section provides additional detail with respect to the Project generally as well as specific Project elements.

Design

The Project's design of the road elements will meet relevant highway design standards with respect to typical design considerations (e.g., shoulder width, lane width, median width, median placement etc.). The number of lanes reflect the inclusion of dedicated transit/HOV facilities and the anticipated 2045 traffic volumes and operational simulations. Technical analysis confirming the requirement for a 10-lane facility was undertaken and is presented in the George Massey Tunnel Replacement Project Traffic Data Overview Report (Government of B.C. 2015a). A summary of this analysis is provided in **Section 1.4 Assessment of the Project Alternatives**.

The Project roadway design minimizes overall land requirements and provides net benefits to agriculture while ensuring no net loss of agricultural land.

Typical upgraded highway cross sections along the alignment are shown in the **Reference Concept (Section 16.1)**, drawings EA-H-3001 and 3002).

Seismic Design Criteria

The seismic design for the new bridge and associated structures (i.e., interchanges) will be in accordance with the Canadian Highway Bridge Design Code (CSA-S6-14).

The new bridge will be designed to a lifeline standard and as such, site-specific seismic inputs have been developed for the crossing. Seismic inputs are based on real earthquake records from around the world that have been adjusted to reflect conditions in the Lower Mainland. Stringent limits for acceptable post-earthquake damage will be achieved through seismic load performance requirements. Ground improvements (see **Section 1.1.7.5 Construction – Ground Improvements**) will be used to reduce lateral loads on bridge foundation piles and to maintain the integrity of the new bridge foundations.

Climate Change Adaptation

All new projects being planned and constructed by the Ministry require that engineering and design work evaluate and consider vulnerability associated with future climate change and extreme weather events and to include appropriate adaptation measures to mitigate against future consequences over the design life of infrastructure. Design considerations to guide climate change planning are provided in the Ministry's Technical Circular T-06/15 Climate Change and Extreme Weather Event Preparedness and Resilience in Engineering Infrastructure Design (B.C. MOTI 2015b).

Bridge Foundation Design

Extensive geotechnical investigations have been undertaken to establish foundation design parameters for the new bridge. Large-diameter, driven pipe piles would be a conventional solution and piles would be installed to a depth of between 65 m and 85 m. The new bridge will be constructed such that piles, ground improvements, and the foundations for the bridge towers will be located above the high water level, with no permanent works below the high-water level.

Navigational Clearance

The Bridge design, which has been informed through dialogue with VFPA, Transport Canada (TC) and marine users, and will meet the requirements of the *Navigation Protection Act R.S.C., 1985, c. N-22*. Based on guidance from VFPA and TC, the new bridge design will provide for navigation clearances similar to those at the Alex Fraser Bridge. This information will be included as part of applications submitted for approvals required under the *Navigation Protection Act*.

The new bridge navigational clearance is shown in the **Reference Concept (Section 16.1, drawing EA-B-GEN1)**.

Railway Crossings

The Project crosses railways at Shell Road and at Rice Mill Road in Richmond and at the British Columbia Railway Company (B.C. Rail) Overhead in Delta. Impacts at these locations are:

- Shell Road – None; the existing highway bridge over the railway can be removed and replaced with no impact on railway operation.
- Rice Mill Road – CN has a spur line that runs along Rice Mill Road and crosses the Tunnel approaches on a structure. The Tunnel approaches will be backfilled at the completion of the Project.
- B.C. Rail Overhead – None; Highway 99 passes under B.C. Rail between Ladner Trunk Road and 112th Street and modifications Highway 99 can be made with no impact on the railway overhead.

Design and construction of new highway infrastructure adjacent to railways will take into account and comply with the following regulations and codes of practice:

- *Railway Safety Act* and associated regulations.
- *Canadian Transportation Act* and associated regulations.
- American railway engineering and maintenance-of-way manual.
- CN and B.C. Rail design specifications.

Stormwater and Drainage Infrastructure

The Project design provides for existing and anticipated drainage requirements adjacent to the Highway 99 corridor. It also will accommodate stormwater management and treatment along Highway 99, including that generated off the deck of the new bridge.

Stormwater management infrastructure will adhere to best practices in B.C. and will be consistent with the concept of integrated stormwater management. As such, design and construction of the drainage infrastructure will take into account hydrological requirements and habitat values associated with drainage features.

The new drainage infrastructure along Highway 99 will be developed with reference to the following documents:

- B.C. Supplement to TAC Geometric Design Guide, Section 1000 (B.C. MOTI 2007a).
- B.C. Supplement to CAN/CSA-S6-06 (B.C. MOTI 2007b).
- Culverts and Fish Passage Fact Sheet (B.C. Ministry of Transportation 2013).
- Stormwater Planning: A Guidebook for British Columbia (B.C. MOE 2002).

- Best Management Practices (BMP) Guide for Stormwater (Metro Vancouver 1999).
- Stormwater Source Control Guidelines (Metro Vancouver 2005).
- Urban Stormwater Guidelines and BMP for Protection of Fish and Fish Habitat (Fisheries and Oceans Canada 2005).
- Land Development Guidelines for the Protection of Aquatic Habitat (Fisheries and Oceans Canada 1993).
- Drainage Factsheet – Agricultural Drainage Criteria (B.C. Ministry of Agriculture, Food and Fisheries 2002).

The following performance objectives will guide the development of final stormwater management infrastructure designs:

- Provide improvements to infrastructure or alternate flow paths to maintain system water levels at pre-Project levels during a 10-year design storm event and as close as feasible to pre-Project levels during a 100-year design storm event.
- Ensure improvements to drainage features avoid or mitigate flow volume increases to municipal pump stations.
- Incorporate water quality BMPs to treat surface runoff such that overall water quality is maintained or improved by the proposed works.
- Provide water quality treatment upstream of locations where highway runoff discharges into irrigation systems.
- Provide fish-passage features in drainage infrastructure, such as culverts, in fish bearing streams.
- Provide opportunity for environmental enhancement areas to offset environmental impacts of the proposed works.

Based on calculations of the impervious area that will be added as a result of upgrading the existing highway, the increase in additional storm water generated as a result of the Project is anticipated to be small relative to the amount of water draining from the area. Existing drainage standards of Richmond and Delta will inform the final drainage infrastructure designs to ensure that incremental Project-related increases in storm water do not compromise the ability to meet existing drainage requirements and not overwhelm the capacity of existing pump stations.

To minimize the increase in stormwater peak-flow rates generated by the proposed work, stormwater storage facilities, including biofiltration ponds, will be used to limit peak flows to pre-Project levels. These storage facilities will double as water quality treatment facilities. Potential stormwater detention pond locations include space under the new bridge and within the interchange ramp footprints **Table 1.1-4**.

Table 1.1-4 Proposed Storm water Storage Structures

| Storage Structure Location | Type |
|-----------------------------------|-------------|
| Steveston Interchange | Pond |
| New Bridge (Richmond) | Pond |
| New Bridge (Deas Island) | N/A |
| New Bridge (Delta) | Pond |
| Highway 17A Approach | Swale |
| Highway 17A Interchange | Pond |
| Highway 17 Interchange (North) | Pond |
| Highway 17 Interchange (South) | Swale |

To minimize runoff volume increases that would need to be managed through the existing pump stations, bridge runoff will be discharged through gravity outfalls that are independent of the municipalities' pumped systems.

Biofiltration ponds and roadside swales will be used where possible to provide sediment capture and infiltration features that will facilitate improved water quality.

Lighting Design

Functional roadway lighting will be provided on the Highway and at interchanges according to TAC and Ministry standards.

Lighting for the multi-use trails and public spaces will be designed to meet functional, safety and Crime Prevention Through Environmental Design (CPTED) requirements. The type of lighting to be used, and orientation of lighting relative to existing development, will focus on meeting safety requirements while avoiding light spill onto adjacent (non-road) areas. Dark sky objectives will be incorporated.

Navigation lighting for marine users and aircraft will be included on the new bridge.

Heritage Considerations

Recognizing the importance of the Highway 99 corridor in facilitating regional growth and development, the Ministry has undertaken a study to identify historic considerations associated with the Highway 99 corridor. The study will inform efforts to recognize and acknowledge the history of the area and the role of the corridor and Tunnel in its evolution.

1.1.7.2 Alternative Transportation Considerations

In addition to providing capacity to meet future vehicle traffic demand, the Project supports broader transportation choices, including significant measures to encourage greater use of transit, car-pooling, cycling, and walking.

Transit/High Occupancy Vehicles

Recognizing that a key goal of the Project is to support increased transit on the Highway 99 corridor, the Project includes significant improvements to transit infrastructure between the Bridgeport Canada Line Station and Highway 91 in Delta. The new dedicated median transit/HOV lanes over the length of the Project will also provide new opportunities for car-pooling. Specific improvements include:

- 50 lane-kilometres of new dedicated transit/HOV lane in the median of Highway 99 between Bridgeport Road in Richmond and Highway 91 in Delta.
- A dedicated transit road under the Oak Street Bridge to improve connectivity for buses between the Bridgeport Canada Line Station and Highway 99.
- A dedicated transit ramp between Highway 99 and Bridgeport Road to provide safe and reliable access for buses destined to or from Canada Line at Bridgeport Station.
- A dedicated transit ramp at Highway 17A for southbound buses destined for Ladner, Tsawwassen and BC Ferries.
- Transit stops, with stairs and elevator access for pedestrians and cyclists, will be integrated with the median transit/HOV lanes and the interchanges at Steveston Highway and Highway 17A.

The new bridge also is designed to accommodate future rapid transit as population density and transportation demand south of the Fraser increases in the future. Specific design considerations that provide for future rapid transit include:

- Deck configuration that allows the conversion of transit/HOV lanes to rapid transit lanes when needed.
- Grades on the bridge that are appropriate for rapid transit applications.
- Bridge design that accommodates rapid transit loads.

Cycling and Walking

Key links in the municipal pedestrian and cyclist networks across Highway 99 and across the Fraser River will be upgraded as part of the Project as summarized below. Improvements to cycling and pedestrian infrastructure include multi-use pathways on both sides of the new bridge. Interchange improvements will include upgraded pedestrian and cyclist facilities.

In Richmond, Project-related cycling improvements include:

- A multi-use pathway that will connect Odlin Road, a current cycling route in Richmond, with the Shell Road Greenway.
- Multi-use pathways on the proposed overpasses at Westminster Highway and Blundell Road.
- Multi-use pathways at the Steveston Highway interchange that keep cyclists and pedestrians separated from road traffic, while accommodating access between the bridge and the integrated transit stops, and between Steveston Highway and the new bridge and Rice Mill Road.

In Delta, cycling improvements within the Project alignment include:

- A connection between pathways on each side of the new bridge to access the Millennium Trail, River Road and Vasey Road. The connection at River Road will link to the existing cycling access for Highway 17A, and 64th Street in Delta.
- The Highway 17A interchange will include a separated multi-use pathway through the interchange with connections to Highway 17A and 62B Street and the integrated transit stop within the interchange.
- Overpasses at Matthews Interchange and 112 Street will also include multi-use pathways.

From a safety perspective, Project-related cycling improvements provide considerably safer alternatives than existing routes through provision of connections where none exist today and through the emphasis on grade-separated multi-use pathways where practical, especially at the Steveston and Highway 17A interchanges.

Smart Transportation

Recognizing that the Highway 99 corridor is an integral part of the regional road network, the design of the Project will incorporate smart transportation elements to support improved traveller information and efficient operations including incident identification and response.

1.1.7.3 Project Design

The Project description provided in the Application describes a Reference Concept for the Project, including a conceptual level design for key Project elements that are required for the proposed infrastructure to operate efficiently and meet performance objectives.

As discussed in **Section 1.1.8.4**, the Project will be delivered by a Contractor that will be responsible for the final Project design, construction approach, staging, and schedule, as well as operation and maintenance.

The Reference Concept described in this Application reflects a level of design adequate to identify and address significant constraints, evaluate and minimize risk, and limit the potential impacts of the Project. In this context, the extent and nature of environmental effects described in this Application are those that would be anticipated to occur assuming the Reference Concept is developed.

While it is anticipated that this level of detail is sufficient to support the environmental assessment of the Project, the design-build nature of the Project allows for Contractor design refinements, which may include innovative designs or approaches to construction that improve operational performance, reduce construction or operating costs, or avoid or minimize potential effects on environmental or community values.

Such changes, if any, will be limited to those that do not result in Project-related effects over and above those described in the Application and do not extend beyond the defined spatial footprint. With these restrictions, the procurement process provides the opportunity for design improvements during Project delivery while ensuring that the extent and nature of potential Project-related effects presented in this Application are not exceeded.

Changes in a certified project may be undertaken subject to consideration by EAO. Under the *Environmental Assessment Act*, substantive variation from the certified Project Description may trigger the requirement for an amendment to the EAC prior to allowing such works to proceed. The amendment process, which includes an opportunity for stakeholder input, provides a mechanism for considering whether proposed changes in project scope could result in potential adverse effects, and confirming that potential additional effects can be mitigated.

1.1.8 Project Activities by Phase

As required in **Section 1.1** of the Application Information Requirements, the following section provides a description of project activities, supported by figures where appropriate, required to construct the proposed Project.

The Reference Concept (**Section 16.1**) includes figures that show the location, design and dimensions of key physical works, including highway widening and various structural components of the Project including the bridge, interchanges, multi-use paths, staging areas required to support bridge construction, integrated transit infrastructure etc.

Following selection of the private sector partner to deliver the Project, detailed design will proceed and additional information will be available with respect to

- Construction approach and staging for highway improvements including widening and interchange construction
- Pre-Construction and Site Preparation
- Preloading, and aggregate and pre-load materials storage
- Temporary access roads and detours
- Temporary drainage structures
- Erosion and sediment control measures
- Temporary barging facilities
- Temporary lighting
- Establishment of site office(s) and temporary staging and laydown areas

The Contractor's designs will conform to all applicable design criteria, technical requirements and constructability and traffic management considerations as well as special considerations for construction of structures, including deck installation methodologies.

1.1.8.1 Site preparation

Site preparation activities are required to collect design-related data or to make way for construction activities. Site preparation activities typically include the following:

- Surveying – Defining the extent of area where construction works will take place and locate site access roads, temporary detours, utilities and property accesses, and sensitive areas.
- Geotechnical investigations – Assessing existing ground conditions within the Project corridor, including confirmation of pile capacities. Locations where ground improvements are required will be identified through compaction testing and collection of soil core samples.
- Clearing and grubbing – Removing of existing vegetation where required for highway widening and improvement activities. Activities will take place within the right-of-way and will include the removal of organic material and soils that are unsuitable for construction.
- Temporary drainage structures- Establishing of works to maintain existing drainage patterns and manage stormwater runoff within the Project alignment while accommodating temporary access routes and detours.

- Erosion and sediment control measures – Establishing of infrastructure to minimize soil erosion and prevent the release of sediments into water courses during site preparation and other pre-construction activities.
- Staging and laydown areas – Establishing of areas for the staging and/or storage of materials and/or heavy equipment such as cranes and construction materials. Wherever possible, staging and lay-down areas will be placed in previously disturbed areas within the Project alignment.

1.1.8.2 Construction

Temporary Works

Temporary works required to provide temporary access to construction areas include:

- Establishing of access roads and detours – Providing access to construction areas, and isolating construction activities from public traffic. Traffic patterns and property access within the Highway 99 corridor will be maintained throughout the pre-construction and construction phases. A Construction Traffic Management Plan (**Section 12.0 Management Plans**) will be developed to describe the approach to traffic management that will be undertaken during Project construction.
- Temporary lighting – Installing of lighting required to facilitate construction. Community notifications will be undertaken in advance of installation and use of any required nighttime lighting.
- Temporary barging facilities – Establishing temporary barging facilities to facilitate movement of materials and minimize the use of regional and local roads. Barge facilities may be required to assist with the delivery of construction materials. All temporary barge facilities would be removed once no longer required.
- Temporary bridges – Constructing temporary bridges on either side of the existing Deas Slough Bridge to access to Deas Island. These temporary structures will be removed when the bridges are no longer required.

Ground Improvements

Ground improvements are undertaken to minimize settlements and to improve seismic performance. Two ground improvement methods that could be used to support the Project include:

Preloading

Pre-loading is often used to control settlement in areas where there are weak soils. Preloading involves the placement of sand onto the compressible soils, to consolidate underlying material in areas that will support road bed and associated infrastructure. Sand used for pre-load is typically applied in discrete layers to build the amount of load required to achieve the desired level of soil compaction in underlying materials.

Densification

For structures in areas underlain by loose sands prone to liquefaction, ground densification treatment may be required. An example of a ground densification technique is vibro-replacement with stone columns. This technique involves lowering a vibrating probe 20 to 30 m into the ground using water jets and backfilling the cavity created by the probe with clear crushed stone while vibrating to densify the ground and crushed stone.

Highway Widening and Paving

Construction works required to develop proposed highway upgrades include the construction of new lanes within the Highway 99 right-of-way as well as replacement of existing interchanges and over/underpass structures.

General activities that will be undertaken to support highway upgrades include:

Embankment construction

Embankment construction involves removal of unsuitable material and placing of fill or expanded polystyrene (EPS) where there is a requirement to minimize weight. Often embankments are retained by walls to minimize footprint. When walls are not used, the embankment edges slope from the finished to the existing grade at a ratio of 3:1 (i.e., width to height). Slopes are seeded or landscaped in their final configuration. In soft soils, preloads are placed in advance of building the embankment to minimize settlement.

Road base construction

Typical road base preparation for the at-grade sections of the highway will include the following:

- Excavating of unsuitable soils, replacement with suitable material from borrow areas and compacting of the replacement soils
- Establishing of a sub-grade, (the soil surface on which the road will be built) by placing fill on soils that are suitable for construction to achieve the appropriate grade (level) and density (compaction)
- Placing of gravel on the sub-grade, followed by topping with a base-course. The base-course consists of layers of gravel, each of different size.

Paving and line painting

Typically asphaltic concrete, a mixture of liquid asphalt and aggregates in a hot mix solution, is used for road surfaces in B.C. This mixture is prepared off-site and transported to the project where it is applied and rolled to a smooth surface. Asphalt pavement can be produced in a variety of manners to deliver different qualities as required.

Road surfaces will have lane markings in accordance with contract requirements. Lane markings include a reflective component that improves visibility for night driving.

Installation of sign bases, signs, and lighting

Construction signs and new directional signs will be required. Installing highway sign foundations may require excavation and in some cases foundation piles, depending on soil conditions and size of the sign. Sign bases can vary in size; moderate sized excavations and structurally sound foundations are required for large directional signs that span the width of the road, while minor works are required for small signs. Both types of signs will be required at various locations, as dictated by the Ministry specifications.

Interchange and Overpass/Underpass Construction

Interchange and over/underpass construction includes roads, structures, retaining walls and embankments, followed by removal of existing structures once the new structures are in service.

Embankment and road construction for interchanges is the same as for highway widening works.

Construction of interchange structures, overpasses, and underpasses includes undertaking ground improvements, installing foundations, constructing concrete pile caps and piers (substructure), erecting girders, constructing concrete deck (superstructure), and removing existing infrastructure. Ground improvement activities supporting the construction of structures are as described previously. Additional construction activities supporting the development of interchanges and overpasses/ underpasses are described below.

Foundations

Due to the nature of the soft soils along the corridor, many of the new structures will require the use of deep, driven/vibrated or drilled pile foundations. Based on preliminary testing, it is anticipated that the contractor will most likely use driven steel tube piles, which may be partially filled with concrete after driving.

Substructure

Reinforced concrete will most likely be used to construct the concrete piers and abutments. Depending on access to the work site, concrete will be placed using a chute directly from the truck, crane and bucket, or pump truck, or precast concrete will be used.

Superstructure

Interchange and over/underpass superstructures will be constructed with steel girders and/or pre-cast pre-stressed concrete girders and reinforced concrete deck slabs. Girders will likely be lifted into place using one or two cranes or launched from one end of the structure.

After the main superstructure elements (the girders) have been placed, the deck will either be cast in place using conventional formwork or partial depth pre-cast deck slabs will be used as stay-in-place formwork. After the superstructure is complete, compacted backfill will be placed up to the abutments.

Decommissioning existing structures

Many existing structures will be replaced with new structures. Once the new structures are ready, these old structures will be decommissioned. All decommissioned elements, including concrete piers, pre-cast concrete girders, cast-in-place concrete decks and concrete parapets or steel railings will be recycled, or disposed of at an appropriate facility.

The Contractor will provide a decommissioning plan containing specific procedures, including any traffic management plans that may be required to support disassembly and removal. Decommissioning activities will be undertaken in compliance with environmental management plans established for specific demolition works as well as terms and conditions of environmental permits and approvals.

As described in **Section 1.1.8.2**, Project works will be managed to minimize the amount of construction-related waste produced including demolition waste from decommissioned roadway and structures.

New Bridge Construction

The new bridge consists of two parts – the approaches and the river crossing. These will require different construction methods as discussed below.

Approaches

Approach spans will be used to bring the roadway to the elevation required for the river crossing. The approaches will consist of multiple spans constructed using either steel or concrete girders. Approach span construction will include the construction methods discussed in previous sections including:

- Embankment Construction – Embankments will be constructed to a height of approximately eight metres to reduce the length of structure required for the approach spans.
- Foundation construction – Piles will be installed to support the approach spans and soils adjacent to the piled foundations will require densification. On completion of pile driving, the top of the piles are cleaned out and backfilled with concrete.
- Substructure installation – Pile caps will be required to transfer load between the bridge piers and the piles. Pile caps will be cast-in-place reinforced concrete.
- Pier Installation– Piers will be reinforced concrete and could be either precast or cast-in-place. Piers will vary in height from about five metres to more than 50 metres. Pier columns will be sufficiently far apart to allow the existing Highway 99 to continue to operate.
- Superstructure Construction – Construction of the approach span superstructure will be in close proximity to the existing Highway 99 roadway. It is assumed that steel girders will likely be installed using cranes located to the side of the approach spans or by launching them from the abutments. Partial depth precast deck panels would be installed on the steel girders as permanent formwork to allow construction of a cast-in-place concrete deck.

River Crossing

The river crossing will consist of tower foundations, towers, a clear span over the Fraser River, and a backspan on each side of the river to balance the main span. Construction methodologies of these elements are described below.

- Tower Foundations – Tower foundations will be similar to those for the approach spans with approximately 100 large diameter pipe piles required per tower. Stone columns may be required around each pile group to address potential liquefaction.
- Towers – Towers hold the main span's cables and will be in the order of 205 metres tall as measured from existing grade. Towers will be constructed of reinforced concrete. A tower crane mounted on the pile caps will likely be installed to facilitate tower construction.

- Main span – A cable-supported main span of approximately 660 metres is anticipated with the main span deck consisting of a fabricated steel box with either a steel plate deck or a concrete deck. Complete deck sections would be delivered to site by barge and hoisted into place.
- Backspans – Backspans could be either a continuation of the approach spans or similar to the mainspan configuration. If similar to the mainspan configuration temporary works and specialized heavy lifting equipment will be required to transfer deck segments from a barge to shore.

Sequencing and Staging of Bridge Construction

Sequencing and staging of bridge construction will be influenced by the Contractor's construction approach and will be determined in concert with design activities. **Section 16.1 Reference Concept** includes a draft construction staging methodology for the main crossing north and south approaches (**Figures 16.1.1-S-SK01 to SK06** and **16.1.1-N-SK01 to SK06**) that depicts the work to be undertaken and a potential staging approach. The Contractor will provide plans for all elements of the Project including; temporary facilities, detours, staging & laydown areas, etc., that will be finalized through the design submission and review procedures established in the contract.

All staging locations are anticipated to be contained within the Project right-of-way and specific locations will be confirmed once the design of the physical works are finalized. It is expected that over the construction phase of the Project, some staging areas will shift once certain work activities are completed and traffic is relocated. This is similar to the experience on the Port Mann/Highway1 Improvement Project, particularly at interchange locations.

Tunnel Decommissioning

When the new bridge is open to traffic, the Tunnel will be removed. Decommissioning will involve the following activities:

- Removing the central four segments of the Tunnel
- Flooding the remaining two Tunnel segments
- Backfilling the Tunnel approaches
- Removing the ventilation shafts and associated above ground enclosures

The Tunnel consists of the following elements:

- **North and south approach structures** – Structures that allow Highway 99 to transition from above ground to below to access the north and south tunnel portals.
- **North and south portals and ventilation buildings** – Located on the dike on the north bank of the Fraser River and on Deas Island, respectively, these structures provide the transition between the onshore approach structures and the Tunnel segments. These structures also house the electrical and mechanical systems for the pumps and fans used for water and air circulation in the Tunnel.
- **Tunnel Segments** – The Tunnel consists of six, 104 m long segments that form an immersed tube under the Fraser River. The Tunnel was constructed by floating the segments to site where they were lowered into a dredged channel, connected together and then ballasted with a combination of concrete in the Tunnel and riprap on top of the Tunnel.

Key Tunnel dimensions and characteristics of the Tunnel are shown on **Figure 1.1-8**.

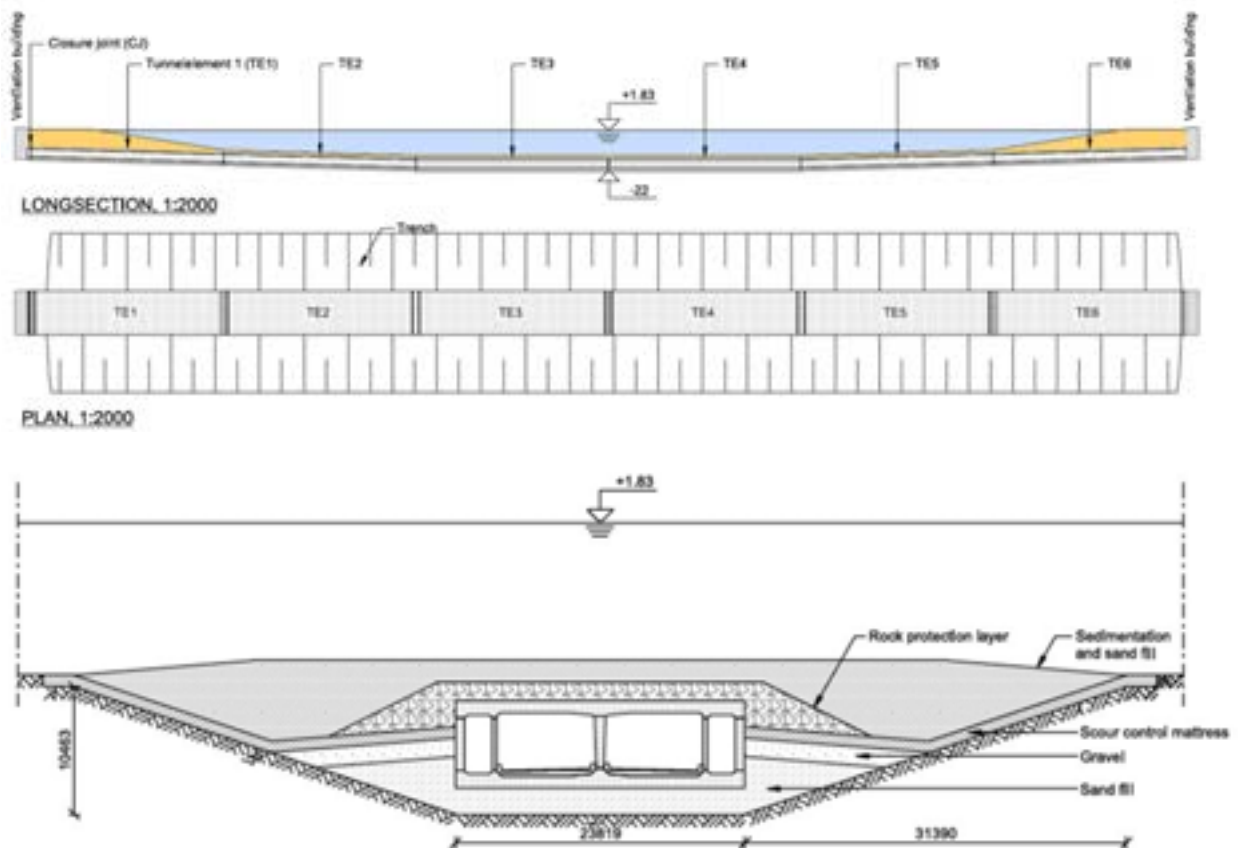

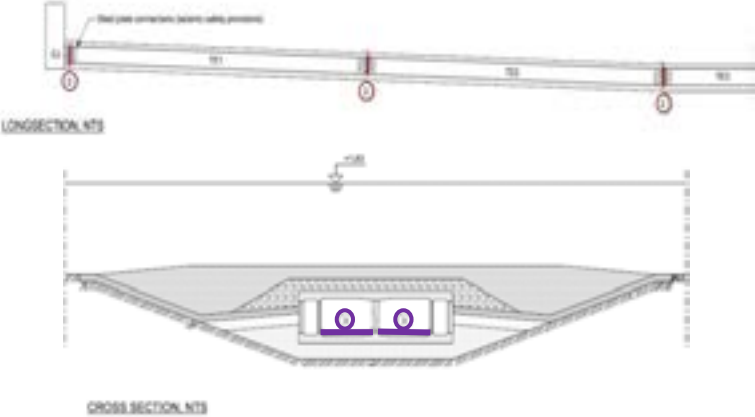

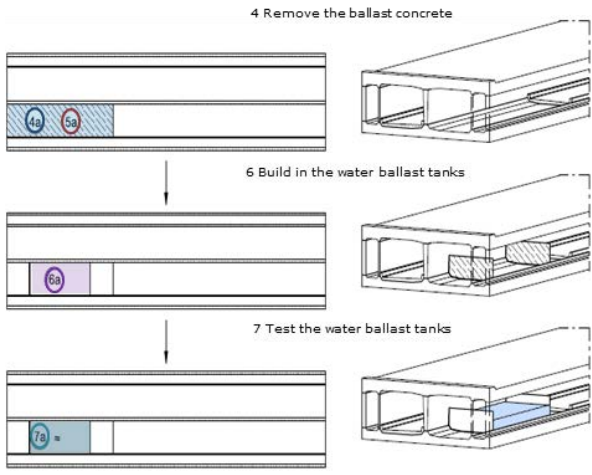

Figure 1.1-8 Tunnel Dimensions and Cross Section

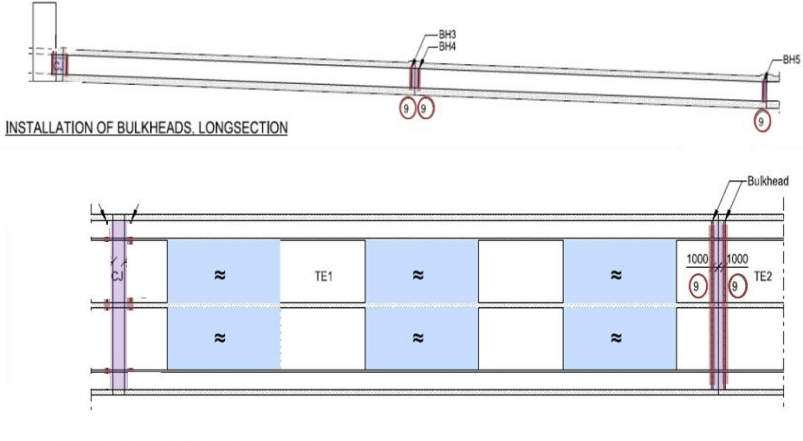

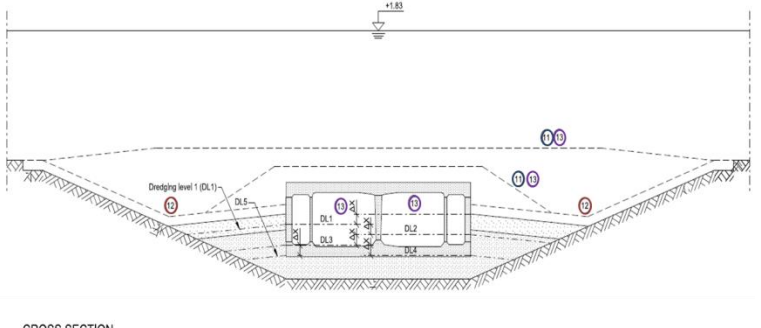

Tunnel decommissioning will involve the sequential removal of instream Tunnel elements and their protective covering by reversing the immersion process that was used to construct the Tunnel. To protect the environment and minimize impacts to marine users during decommissioning, the following requirements will be in effect:

- Maintain navigation in the Fraser River South Arm during Tunnel decommissioning.
- Use BMPs and comply with regulatory requirements, including those related to construction timing windows, notifications, specific mitigation measures.
- Maintain long-term stability and hydrology of the Fraser River South Arm, including water and sediment flow regimes and local ecological conditions.

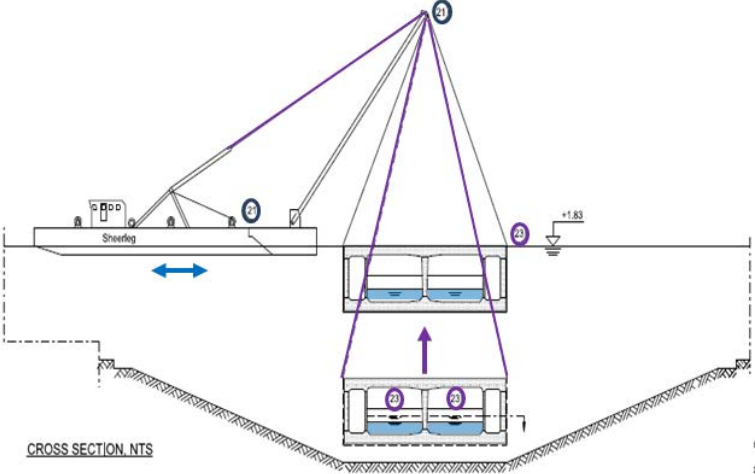

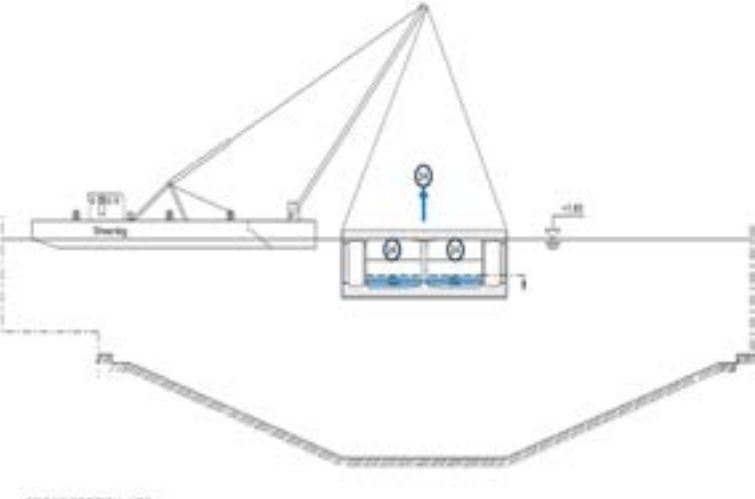

Tunnel decommissioning will be completed within the appropriate construction windows. The Reference Concept for Tunnel decommissioning currently assumes that the four Tunnel elements will be removed over the course of one construction season (i.e., between freshets) and during a window where effects on fish and marine mammals are minimized (**Section 4.4 Fish and Fish Habitat** and **Section 4.6 Marine Mammals**). The process for removing the tunnel segments is outlined in **Table 1.1-5**.

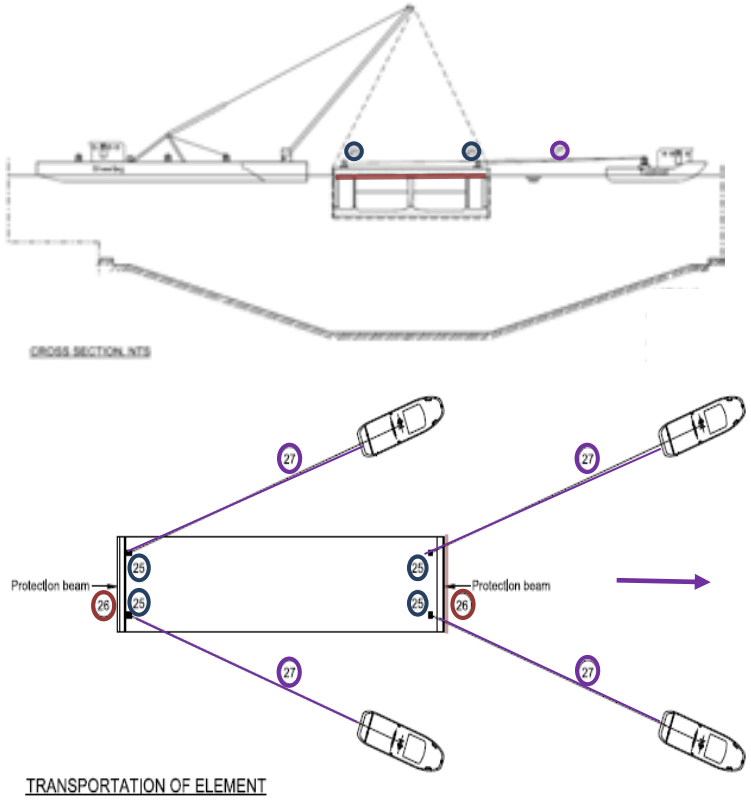

Table 1.1-5 Proposed Sequence of Tunnel Decommissioning Activities

| Decommissioning Activity | Details |
|--|--|
| <p>Permanently close the Tunnel</p> <ol style="list-style-type: none"> 1. Close Tunnel and remove utilities 2. Remove Stage 1 Seismic Retrofit Works 3. Mill asphalt |  <p>The diagrams show the tunnel's internal structure. The 'LONG SECTION, NTS' shows a perspective view of the tunnel with three circular markers labeled '0' along its length. A note above it reads 'Ballast concrete before utility removal'. The 'CROSS SECTION, NTS' shows a top-down view of the tunnel's trapezoidal shape with two circular ballast tanks highlighted in purple at the bottom center.</p> |

The bottom diagram, labeled 'TRANSPORTATION OF ELEMENT', shows the segment being moved by four tugboats. The segment is supported by four points, each labeled with a circled '27'. Protection beams, labeled with a circled '26', are installed at both ends of the segment. The segment is shown moving to the right, as indicated by a purple arrow.</p> |

Tunnel segments will be removed sequentially starting at either the north or south side. Shipping will be maintained during removal operations although reducing the navigation to temporarily be one-directional may be required. Back filling after the Tunnel segments have been removed will occur naturally and is anticipated to take about approximately seven months (**Section 4.1 River Hydraulics and River Morphology**). The Metro Vancouver watermain downstream of the Tunnel will be monitored against baseline measurements and additional scour protection will be provided if required.

The approaches to the Tunnel consist of concrete retaining walls with a thick concrete floor. These structures will be left in place and backfilled with clean soil material.

The ventilation buildings located between the Tunnel approaches and the instream segments are concrete structures that are approximately 15 metres below existing grade. After removing all non-structural elements and cleaning, the ventilation building in Richmond will be backfilled and incorporated into a strengthened dike on the Richmond side of the river. Consideration will be given to incorporating the ventilation building on Deas Island into an interpretive area to acknowledge the history of the Highway 99 corridor and the Tunnel.

Ancillary Construction Activities

In addition to the activities associated with specific project phases described in previous sections, the following activities are also associated with the construction of the Project.

Staging Areas

Laydown areas will be required during construction for staging of equipment and storage/preparation of construction materials. Laydown areas will be used for temporary storage of construction or demolition materials such as gravel and pre-cast concrete sections, and for assembly of culverts, formwork and reinforcing steel construction. These areas may also be used for site offices, workshops, equipment storage and other related uses.

Previously developed and disturbed areas within the highway right-of-way are available for staging purposes. The Contractor will confirm the number and location of required staging areas based on the detailed Project design and construction staging plan.

Areas within the right-of-way to be used for staging areas will be managed in accordance with Environmental Management Plans including the Construction EMP (CEMP) (**Section 12.0 Management Plans**). When Project construction is complete, any land used for staging areas and not required for permanent Project infrastructure will be restored to its pre-construction condition. In this context, the use of lands within the right-of-way for staging areas is not expected to result in environmental effects over and above those described in the effects assessment sections (**Part B – Assessment of Environmental, Economic, Social, Heritage, and Health Effects**) of the Application.

The Contractor will be responsible for obtaining required permits and approvals for any additional staging areas on lands other than those within the highway ROW, prior to initiating such works.

Utilities Relocation

Utilities within the right-of-way are under a permit from the Ministry. During Project planning to date, the Ministry has met with all potentially affected permit holders to identify utilities that may need to be relocated or protected.

With the exception of those no longer in use, all utilities located within or immediately adjacent to the ROW will be relocated or protected prior to, or during construction. Potentially affected utilities include water, sanitary sewer, gas, telecommunications, and electrical transmission and distribution lines (overhead and underground).

Utilities owned by BC Hydro, BritishColumbia Transmission Corporation (BCTC), Fortis BC, Kinder Morgan, Shaw Communications Inc., TELUS Communications Company, municipalities and others, are located within the Highway 99 corridor. B.C. Hydro is currently taking steps to relocate the existing 230 kv lines that run parallel to Highway 99 and pass through the Tunnel.

Metro Vancouver's Lulu Island-Delta water main that crosses the south arm of the Fraser River downstream of the Tunnel is not directly adjacent to the Project works and will not need to be relocated. **Section 4.1 River Hydraulics and River Morphology** assesses potential effects to this utility as a result of Tunnel decommissioning and presents mitigation that will be undertaken to avoid effects on this infrastructure.

Given the current stage of Project design, detailed utility relocation requirements are yet to be finalized. As part of confirming the final design of the Project, the Contractor will work with utility companies to identify and address utility relocations and avoid service disruptions and associated costs during construction.

Aggregate and Pre-Load Materials

Aggregate will be required for roadbed construction and the manufacture of concrete for bridge construction. It is assumed that aggregates will be sourced from existing pits and quarries within the region and not through development of new aggregate quarries.

Pre-load material required to support ground improvement will also be obtained through existing sources and vendors and no project-specific works will be undertaken to obtain pre-load materials.

Concrete and Asphalt Production Facilities

Concrete and asphalt will be required for Project construction. While there are a number of facilities in proximity to the corridor that are capable of supplying these materials, it is possible that the final design and construction methodology may include the development of concrete and/or asphalt production facilities within the Project area. Such facilities may be established to help reduce the volume and impacts of construction traffic on local and regional roads, and to expedite the construction schedule.

Areas within the ROW to be used for concrete or asphalt production will be managed in accordance with EMPs including the CEMP (**Section 12.0 Management Plans**). When Project construction is complete, land used for concrete or asphalt production and not required for permanent project infrastructure, will be rehabilitated in a manner consistent with its condition prior to its use for concrete or asphalt production. In this context, the use of lands within the right-of-way for this purpose is not expected to result in environmental effects over and above those described in the effects assessment sections (**Part B – Assessment of Environmental, Economic, Social, Heritage, and Health Effects**) of the Application.

In the event that such facilities are required, details regarding their location and operating requirements, including provision of material input and any environmental permit requirements, will be the responsibility of the Contractor, and will be addressed as part of the final design and construction planning.

Waste Disposal

The Project will be managed to minimize the amount of construction-related waste produced. Construction waste includes demolition waste from decommissioning of roadway and structures and excavated material that cannot be used as fill material along the alignment.

Costs and other constraints associated with conventional waste disposal encourage contractors to re-use or recycle waste material. For example, a variety of technologies are available for recycling pavement. Concrete rubble can be crushed and re-used for road base and other applications and reinforcing bars can be separated and salvaged. Contractors will be able to re-use excavated material for applications such as pre-loading and filling, either at locations along the alignment or at off-site construction projects.

Where disposal of waste is necessary, such activities will be conducted in accordance with the *Environmental Management Act*. Construction waste management procedures and approaches to be followed during construction will be described in the CEMP (**Section 12.0 Management Plans**).

The Project, as currently contemplated, is not expected to involve activities that may require a Disposal At Sea Permit pursuant to the Disposal at Sea provisions of the *Canadian Environmental Protection Act*, 1999, c.33. If the need for disposal at sea does arise, it will be the Contractor's responsibility to liaise with the Regional Ocean Disposal Advisory Committee and acquire the necessary permit from Environment Canada in accordance with applicable regulatory requirements.

Construction Site Offices

The requirement for construction site offices and ancillary buildings will be confirmed as part of the completion of the final design of the Project. Areas within the right-of-way to be used for offices or ancillary buildings will be managed in accordance with the CEMP (**Section 12.0 Management Plans**). When Project construction is complete, land used for these purposes and not required for permanent infrastructure, will be rehabilitated in a manner consistent with its prior condition.

Contaminated Sites Management

Since the Project involves excavation, pile driving and other ground disturbing activities, contaminated soil or groundwater could be encountered during construction if the Project alignment overlaps any contaminated sites. Potentially contaminated material may also be encountered during demolition of existing structures. Project-related considerations pertaining to management of potential contaminated sites are outlined below.

A preliminary study involving a review of current and historical land use information to assess the potential risk of contamination was conducted to identify contaminated sites that may be present within or adjacent to the Project alignment.

The study indicated no substantial risk or concerns related to site contamination for properties within and adjacent to the Project alignment, but did identify six properties with a moderate potential for the presence of contamination. Further reviews and field investigations as appropriate will be completed during later Project planning stages to support the effective management of potentially contaminated soils and/or water during Project construction.

Any contaminated soil or groundwater encountered during construction will be managed in accordance with applicable legislation and regulations, including the B.C. *Environmental Management Act*, S.B.C. 2003, c. 53, and associated *Contaminated Sites Regulation*, *Hazardous Waste Regulation*, and the *Waste Discharge Regulation*. Contaminated sites management will be described in more detail in the Project's CEMP (**Section 12.0 Management Plans**).

Hazardous Materials Management

In 2014, the Ministry undertook a study to identify potentially hazardous building materials commonly used during Tunnel construction. The study identified materials within the Tunnel that must be managed appropriately during decommissioning, including materials that potentially contain lead and asbestos that may require control, containment, or removal prior to decommissioning of the Tunnel.

Building on the results of this study, the Contractor will develop a detailed plan for removing and appropriately disposing of potentially hazardous materials. Hazardous building materials will be managed in accordance with the *Hazardous Waste Regulation* and the Workers' Compensation Board of B.C. *Occupational Health and Safety Regulation*.

1.1.8.3 Project Operations and Maintenance

During the operations phase of the Project a number of operations and maintenance (O&M) services and activities will take place to provide for the operation of the Bridge and associated sections of highway alignment. These activities include, but are not limited to:

- Routine operations, maintenance, and rehabilitation of the Highway
- Bridge/structure maintenance and rehabilitation
- Roadside maintenance, including signage
- Drainage maintenance
- Winter maintenance
- Emergency maintenance

- Traffic maintenance
- Line marking
- Electrical asset maintenance
- Culvert replacement
- Slope stabilization
- Interface with stakeholders, communities, the public, emergency services, and the Province

All O&M activities will be carried out in accordance with established environmental best practices, as described in the Operation EMP (OEMP) for the Project (**Section 12.0 Management Plans**). Services associated with ongoing O&M activities will be provided in accordance with defined performance measures , in a manner consistent with the Ministry's *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010).

Regular highway inspections will be scheduled to ensure that maintenance issues are identified and addressed on a continuing and consistent basis. The nature of O&M services varies seasonally with maintenance activities being scheduled at appropriate times of the year. Response times and performance timeframes will be in accordance with contract requirements.

Drainage maintenance and roadside maintenance are ongoing activities that will be undertaken either throughout the year or as needed, based on seasonal requirements and in-stream work windows. Structure maintenance and traffic maintenance (e.g., signage and electrical assets) will be scheduled according to the requirements as identified during highway inspections.

The Contractor responsible for O&M will, as part of the final design, confirm the need for any facilities to store and service highway maintenance vehicles and to store and stockpile roadway maintenance materials and supplies.

Potentially hazardous materials required to support O&M activities will be stored and managed in compliance with local, provincial and federal regulations and Workplace Hazardous Materials Information System (WHIMIS) standards.

The OEMP will include procedures for responding to emergencies including vehicle accidents and spills of hazardous materials.

The Contractor will develop and implement an ISO 9001:2000 certified Quality Management System (QMS) (ISO 2000) that documents the processes and procedures to be used to achieve the requirements. The Ministry will audit the Contractor's systems, procedures and records to verify compliance.

Tolling

The Ministry intends to finance the Project's capital, operating, maintenance, and rehabilitation costs through user tolls. This section outlines the provincial guidelines with respect to tolling highway infrastructure projects and the anticipated tolling system for the Project.

The provincial tolling guidelines (B.C. MOTI 2003) guide tolling of bridges operated by the provincial government. These guidelines are summarized below:

- Only major projects that result in significant capacity increases will be subject to tolling.
- Tolls will be implemented only if there are demonstrable net benefits for the users (user benefits may include time savings, vehicle operating costs, reliability and safety).
- Tolls will be implemented only if a reasonable untolled alternative is available.
- The toll amount and the frequency of increases will be established in advance.
- Public consultation will occur in all cases where tolls are considered.
- The public will have the same rights to access tolled highways as non-tolled highways.
- Tolls will be used to generate revenue for transportation projects and to provide a return on the investment of the private sector partners.
- The same maintenance, safety and other standards, and rules of the road will apply to tolled highways as apply to non-tolled highways.
- The privacy of information used to levy and collect tolls will be protected.
- A fair and expeditious process will be available for resolving tolling disputes.
- The consequences of failing to pay tolls will be fair and reasonable.

Tolling also will help to manage future traffic growth so that the travel time savings, reliability, and vehicle operating cost savings are long lasting.

Key elements of the proposed tolling framework for the Project include:

- A point toll at the bridge.
- A toll rate for four classes of vehicles.
- A fully electronic free-flow collection system.

The point toll model anticipated for the Project involves users paying a toll at the new bridge. Users who do not pass this location are not required to pay a toll. With point tolling, toll collection is commonly located at the most expensive part of a highway corridor, such as a bridge where the major user benefits of the project are realized.

Point toll collection involves the simplest infrastructure, and when combined with modern open road tolling technology, does not require that the traffic stream be stopped for toll collection. This open road point toll system is currently in use at both the Port Mann and Golden Ears Bridges and has proven to be an effective customer-friendly technology over a number of years of operation.

The proposed tolling system will be consistent with the system that is used at the Port Mann and Golden Ears Bridges and will be interoperable with these other existing facilities.

Future regional tolling initiatives

In light of TransLink's plans to construct a new tolled Pattullo Bridge and the Province's plan to toll the new Tunnel replacement bridge, there continues to be vibrant discussion regarding funding future transportation initiatives in greater Vancouver. A number of road pricing options have been suggested, including that all bridges in the region should be tolled.

The Project's Phase 3 consultation program specifically invited feedback on tolling in concert with other elements of the Project Definition Report as described in **Section 11.0 Public Consultation**. Most participants supported some form of tolling. It is anticipated that discussions regarding regional tolling will continue for some time and encompass a broad range of considerations. Any changes to the Provincial Tolling Guidelines may affect additional crossings and would be considered in advance of the anticipated opening of the new bridge in 2022.

Proceeding with self-supporting tolling as currently proposed does not preclude the ability to consider other options such as a longer term regional funding strategy in the future. The Province will also continue discussions with the federal government to explore a funding partnership.

1.1.8.4 Project Procurement and Delivery

The Project will be procured using a Design-Build-Finance-Operate (DBFO) delivery model with a private partner responsible to design, build, partially finance, operate, maintain and rehabilitate the asset for a term of 30 years. This approach is supported by a detailed assessment that has been conducted to determine the procurement model for the Project that is

expected to best meet objectives and provide value to taxpayers. The Procurement Options Report and Business Case provide further detail regarding the analysis of alternative models and are available at www.masseytunnel.ca.

The analysis shows that the DBFO model will best:

- Manage and mitigate key project risks
- Maximize competition, providing innovation and efficiencies
- Maximize corridor service quality and full life asset performance
- Maximize cost and schedule certainty over the full life of the asset
- Provide value for money

Under a DBFO, the contractor is responsible to design and construct the full scope of the Project and assumes all risks related to maintenance and rehabilitation during the operating period. Accordingly, the contractor must carefully consider the long-term rehabilitation requirements and the upfront capital investment to optimize the balance. This extends innovation potential and leverages the expertise of the private sector within a competitive environment so that the final design solutions create value well into the asset's useful life.

The contractor is paid, as set out in the agreement, on achieving key milestones during construction and regularly during operations based on operating performance criteria. Poor performance is subject to penalties until the contractor remedies the problems. By having the contractor commit to a long-term performance-based contract with strict handback conditions, the risk of poor asset performance and deferred rehabilitation is minimized. The DBFO model secures optimal asset quality and performance over the term of the contract and is more likely to result in better asset conditions beyond the term of the contract.

Project procurement will proceed in 2016 to select a private sector DBFO partner. The competitive selection process will include two stages: a request for qualifications (RFQ) stage and a request for proposals (RFP) stage. RFQ respondents will be evaluated based on the strength and relevance of their experience and capability as demonstrated through previous projects. It is anticipated that a short-list of three proponents will be invited to submit a proposal in response to the RFP. The preferred proponent will be selected based on the evaluation criteria set out in the procurement documents.

International and local firms forming joint venture teams are expected to participate in the procurement process. There will be opportunities for local firms to partner/subcontract with these teams. The Ministry is also developing a process to encourage commitment to local participation, including plans for business-to-business workshops that will introduce international firms to local contractors.

Following completion of the procurement process, the successful proponent will finalize the design and proceed with construction. Project delivery will include the engagement of subcontractors and the provision of services aligned with the proponent's purchasing strategy. The breakdown of goods, labour, and services amongst local, provincial, national, and international markets will be influenced by the proponent's design and delivery strategy. Local and provincially based firms are expected to provide a substantial portion of labour and materials during the construction phase of the Project such as design services; supply and placement of asphalt and concrete; electrical and mechanical equipment and services; traffic management; and construction labour.

The overall capital construction cost of the Project is estimated at \$3.5 billion in as-spent dollars. The value of services during the construction phase are anticipated to range between ten and thirty per cent of the overall services for each of the five years of construction; ramping up from year one, with the peak occurring in years two and three and the remainder diminishing through to the completion of construction and commencement of operations.

During the operations phase, annual operating and maintenance costs are estimated in the range of \$15 million to \$25 million, and rehabilitation costs will vary by year (e.g. repaving on a multi-year cycle). It is anticipated maintenance and rehabilitation services will be delivered through a combination of the proponent's in-house resources and local sub-contractors procured through the proponent's purchasing mechanisms.

Further details regarding the estimated value of contracts and services during the construction and operations phases of the Project are confidential as disclosure may harm the negotiating position of the Ministry during the competitive selection processes.

The Transportation Investment Corporation (TI Corp) will oversee the Project and will be responsible for recovering Project costs through tolls.

1.1.9 Costs

The Ministry developed cost estimates for the construction and operations phases of the Project as described in the Capital Cost Estimate Report (Government of B.C. 2015b) and Operations, Maintenance and Rehabilitation Base Cost Estimate Report (Government of B.C. 2015c) based on the reference concept described in this Application. The summary presented below provides an overview of the cost items that were considered in developing of the overall Project capital cost estimate of \$3.5 billion in as-spent dollars. Construction cost categories within the budget estimate include:

- Roadways – site preparation, excavation and fill, paving, barriers, drainage

- Structures – Foundations, substructure, superstructure, approaches, retaining walls
- Tunnel Decommissioning.
- Utilities
- Systems – ITS System, signage/lighting/traffic controls, tolling infrastructure
- Environment – Noise mitigation, habitat enhancement, biofiltration/stormwater management
- Project Management/Engineering – Project management, engineering, health and safety, community relations
- Property – property acquisition, licenses to construct

The substantial majority of capital construction costs is associated with structural elements including the new bridge, new interchanges and Tunnel decommissioning. These elements comprise approximately two-thirds of the overall cost. The Roadway and Systems categories which include highway widening, transit infrastructure and ITS and related work throughout the Project corridor, collectively approximate ten per cent of the construction estimate.

Annual operating costs are estimated in the range of \$15 million to \$25 million. Key operating cost categories include:

- Routine road and bridge maintenance - – surface, drainage, roadside, signage and lane markings, winter maintenance etc.
- Additional services – cable maintenance, maintenance of joists and bearings, painting of structural components, etc.
- Electrical maintenance - traffic signals, lighting.
- General administration/contract support

A breakdown of costs for each construction and operations category as well as anticipated timing of expenditures has been developed and incorporated in the Capital Cost Estimate Report and Operations, Maintenance and Rehabilitation Base Cost Estimate Report. Details regarding specific quantities, costs or cash flow are confidential pending conclusion of the procurement process as disclosure may harm the negotiating position of the Ministry during the DBFO competition to select the private sector partner.

1.1.10 Business Case

A Business Case has been developed that establishes the need for investing in improvements to the Highway 99 corridor and how the Project will contribute to the objectives and strategies to improve transportation infrastructure in greater Vancouver. The George Massey Tunnel Replacement Project Business Case (Government of B.C. 2015d) includes an assessment of the key economic and other benefits of the Project, relative to its costs. Following is a summary of the methodology undertaken and the key conclusions.

Project benefits considered in the business case include:

- **Quantified user benefits** – including travel time, reliability and vehicle operating cost savings, traffic safety, and seismic risk reduction.
- **Unquantified user benefits** – including benefits to cyclists/pedestrians; benefits to future transit; and other unquantified benefits.
- **Economic development benefits** – including increased economic activity and employment, both during construction and in the longer-term.
- **Social, community and environmental benefits and considerations** – such as improved community connectivity; improvements to Deas Island Regional Park; improved emergency response capability; and restoration of the Fraser River shoreline.

Benefits and costs are estimated based on the initial scope of the Project, including a 10-lane bridge (with dedicated transit/HOV lanes, multi-use cyclist/pedestrian pathways, replacement interchanges, highway widening, and tolling similar to the Port Mann and Golden Ears Bridges), compared to the baseline option of maintaining the four-lane Tunnel.

The methodology is based on economic benefit-cost analysis principles, estimating present value (PV) of Project benefits and costs in accordance with provincial guidelines. The analysis of economic benefits and costs is performed in “real” (net of inflation) 2014 dollars with an annual discount rate of six percent applied to future-year benefits and costs. Benefits have been estimated over a 35 year planning horizon.

When compared to the base case of maintaining the existing Tunnel, the Project provides benefits to users as well as to the economy in terms of economic development and employment. In addition, there are socio-economic and other community and environmental benefits anticipated.

The Project capital costs are estimated at \$3.5 billion in as-spent dollars. The present value of net Project costs is approximately \$2.0 billion in 2014 dollars, before allowing for interest during construction.

The summary provided in **Table 1.1-6** shows that the net present value of user benefits is estimated at approximately \$2.5 billion, and the net present value of economic development impacts is in the range of \$1.6 billion. When compared to the net present value of the Project costs, these benefits represent a benefit-cost ratio of 2.1:1; more than twice the Project costs.

Table 1.1-6 Present Value of Benefits and Costs

| | Present Value (2104\$M) |
|--|--------------------------------|
| Total Net Project Cost | \$2,016 |
| Travel Time, Reliability, Operating Cost Savings and Safety/Seismic Benefits | \$2,485 |
| User Benefit/Cost Ratio | 1.2:1 |
| Economic Development Benefits | \$1,652 |
| Total Benefits | \$4,137 |
| Total Benefit/Cost Ratio | 2.1:1 |

The Project also provides for additional unquantified social, community, and environmental benefits as compared to the base case, including:

- Benefits to pedestrians and cyclists
- Benefits to transit users
- Reduced local traffic congestion
- Improved emergency response capability
- Improved cross-highway agricultural and local community connections
- Deas Island Regional Park enhancements
- Environmental restoration/improvements to the river shoreline and land/marine habitat
- Greenhouse gas reductions
- More efficient support of Metro Vancouver’s projected growth in population and employment
- Support of TransLink’s Regional Transportation Strategy

The benefit-cost outlook for the Project is favourable based solely on user benefits such as congestion relief and increased safety, even before considering economic development and job creation as well as benefits for cyclists/pedestrians and local community and recreational users.

1.1.11 Project Benefits

As a key component of the regional, provincial and national transportation system, the Project has been developed to address safety, community, economic, and environmental challenges associated with current and forecast traffic demands at the Tunnel. As such, advancing the Project is anticipated to result in a number of benefits. The following section summarizes Project benefits to economic, social, environmental and health values in local and regional communities. The benefits identified in this section have been determined through studies undertaken to support Project planning.

1.1.11.1 Economic

Employment during construction

Project planning and construction expenditures are estimated to result in direct employment benefits of more than 9,000 jobs. This estimate includes project management, design and engineering, as well as direct employment in construction (Government of B.C. 2015b). In addition, indirect employment benefits of more than 8,000 jobs are estimated for the businesses that support and supply the direct construction activities.

Job numbers are estimated based on the number of individuals employed, while full-time-equivalent (FTE) positions are estimated using an average of 1,750 hours per year. Construction industry workers typically work overtime, i.e. more than the standard weekly hours on which FTE estimates are based. Using the FTE method, the construction employment estimate is approximately 11,000 direct FTEs, plus 8,500 indirect FTEs.

Wage and earning levels in the construction industry are high, and the average income for transportation engineering construction jobs is estimated to be more than \$90,000 annually.

Construction will take place on a year-round basis, with limited seasonal impacts for certain activities (e.g. paving).

Employment during operations

The Project also will directly generate additional permanent jobs, to support ongoing operations and maintenance activities. Based on the experience of the Port Mann/Highway 1 Improvement Project, employment during operations (road and bridge maintenance, tolling, administration) is expected to be in the range of 60 to 90 permanent direct jobs, primarily full-time. Indirect employment during operations is estimated as an additional 60 to 70 permanent jobs.

Wage rates for these permanent positions vary by function, and will be aligned with levels in comparable situations in the Lower Mainland. For example, road and bridge maintenance contracting staff working on the Port Mann/Highway 1 Project inventory have wage levels in the range of \$25 to \$38 hourly, consistent with annual earnings in the range of \$45,000 to \$65,000 in 2011 dollars (prior to cost of living adjustments).

The majority of construction and operations jobs are expected to be filled from within BC, as has been the case with other Lower Mainland transportation projects in recent years.

Tax revenues during construction

During the construction program, the estimated tax revenue impact is \$518 million. This includes \$301 million in tax revenues generated as a result of direct construction activities (mainly income taxes, and some taxes on products), \$164 million from industries further back in the supply chain, and \$53 million in industries benefitting from spending by workers.

By level of government, the \$518 million in tax revenues during construction includes \$162 million accruing to the federal government, \$135 million to the provincial government and \$4 million to local governments (BC Stats 2015).

Tax revenues during operations

During the operations phase, the tax revenue impacts are forecast to follow the annual pattern of contractor construction expenditures, as described in **Section 1.1.7.4**, Project Procurement and Delivery. Annual tax revenues from operating expenditures are estimated at \$4 million per year, including \$2.2 million to the federal government, \$1.6 million to the province, and \$0.3 million accruing to local governments. Most of the ongoing federal and provincial tax revenues are income taxes, while most of the local government revenues are property taxes.

Vehicle travel time savings and reliability during operations

The new bridge will relieve congestion, resulting in important direct user benefits (improved travel times and reliability, reduced vehicle costs, etc.) Travel time savings benefits of 25 to 35 minutes per day for round trip commutes are forecast in the initial year of operation, resulting in more than \$70 million in avoided congestion costs. These user benefits will increase over time, relative to the increasingly congested situation under continued Tunnel operation (Government of B.C. 2015).

Over a 35-year planning horizon, the total economic benefit of travel time savings, is estimated at \$ 1,977 million (Government of B.C. 2015d), reflecting the following types of travel time benefits:

- Time Savings for Weekday Traffic – Current and future Tunnel congestion delays will be eliminated with the operation of the new bridge, resulting in immediate travel time savings for traffic, especially during peak periods.
- Time Savings for Weekend and Holiday Traffic – The new bridge will better accommodate seasonal variations in demand. Traffic and congestion patterns at the Tunnel vary on a daily and seasonal basis, with the greatest delays experienced by the one lane of northbound afternoon traffic (e.g., 45-50 minutes delays on Friday afternoons in August, and often higher).
- Increased Travel Time Reliability – Congestion-related delay times are highly variable from day to day. For example, while the peak delay times for morning mid-week traffic at the Tunnel average 8 minutes, actual delay times from day to day typically range up to more than 20 minutes. The new bridge’s improved reliability will eliminate the need for travellers to build extra time allowances into their travel plans as a guard against arriving late at their destinations.
- Benefits for same-side traffic – Reconstruction of, and improvements to, the existing Highway 17A and Steveston Highway interchanges will provide further travel time savings and reliability benefits for traffic that is not travelling across the new bridge. In particular, significant improvements are being planned for Westminster, Steveston and Highway 17A that will improve cross-highway connectivity and the flow of local traffic.

Vehicle operating cost savings

In addition to travel time savings, the new bridge will also result in reduced vehicle operating costs. The present value of vehicle operating savings, over the 35-year horizon, has been estimated at \$182 million (Government of B.C. 2015d). These savings will result from:

- Reducing congestion-related travel delay times, and increasing average vehicle speeds, resulting in better fuel economy.
- Reducing the wear and tear on vehicles associated with stop-and-go traffic during congested conditions.

Safety benefits

The new bridge also will result in significantly increased safety levels, both in terms of traffic safety and seismic resilience levels.

The Tunnel is designed to 1950s safety standards. Based on a review of current collision rates at the Tunnel and adjacent intersections, and considering the reductions achieved at the new Port Mann Bridge, a 35 per cent overall reduction in collision rates is forecast for the new.

The new bridge also will be designed to modern seismic resistance standards, increasing the crossing's level of seismic resistance from the current 1-in-275-year-earthquake to a future 1-in-2,475-year-quake.

Commercial vehicle economic benefits

By addressing peak-period Tunnel congestion, the new bridge will enable efficient scheduling of commercial vehicle movements throughout the day.

Agricultural economic benefits

Through engagement with the Delta Farmers Institute, the Richmond Farmers Institute and farmers with operations in the vicinity of the Tunnel, the Ministry has worked to ensure that the Project will have important agricultural economic benefits in addition to those described above. These unquantified benefits include:

- Less spoilage/waste as a result of the improved reliability in getting perishable goods to market.
- Increased efficiency of farming operations as a result of the improved travel times and improved access between farms on both sides of Highway 99.
- Improved drainage and irrigation ditches along Highway 99, which will help improve the productivity of existing agricultural lands.
- Potential increase in land available for farming.

Long-term economic development benefits

A number of studies have noted the substantial impacts of traffic congestion on economic development. For example, a 2015 study for TransLink and the Metro Vancouver Mayors' Council estimates that, in 2011 dollars, "...the costs of delay and excess traffic effects (excess time, vehicle costs, accidents, and emissions) amount to about \$407 million and the lost GDP amounts to nearly \$321 million" (MVMC 2015).

Based on the results of a major study of the effects of Lower Mainland transportation infrastructure on economic growth, undertaken by the Greater Vancouver Gateway Council (Delcan 2003), the Project is forecast to increase the rate of regional GDP growth by about \$13 million per year starting in 2021 (Government of B.C. 2015*d*). By 2045 increased rate of

growth is forecast to result in incremental GDP growth of \$325 million per year, and incremental employment (direct, indirect and induced) of approximately 4,500 to 5,000 permanent jobs. The present value of this incremental GDP growth is estimated at \$1.652 billion (Government of B.C. 2015d).

Support for regional population, employment and economic growth targets

Metro Vancouver's regional growth strategy (Metro Vancouver 2015) forecasts that population and employment growth south of the Fraser (Richmond, Surrey, White Rock, Delta, and Tsawwassen) will grow by more than 60 per cent between 2006 and 2041 (an average growth rate of more than 1.4 per cent per year). The new bridge will remove the major bottleneck on the Highway 99 corridor, supporting economic growth in these communities and helping to achieve local and regional population and employment targets.

1.1.11.2 Social and community benefits

Support for local and regional land use and transportation plans

As discussed in **Section 5.1 Traffic** and **Section 5.3 Land Use**, the Project will provide social and community benefits associated with infrastructure that complements the goals and objectives of local and regional land use plans as well as TransLink's Regional Transportation Strategy. Specifically, the Project design, including enhancements for transit, HOV, cycling and pedestrians, will help to address future transportation needs that are anticipated with projected population and employment growth in a manner that supports regional objectives for more sustainable modes of travel.

Improved mobility and transportation choices

As noted in the **Section 1.1.7.1**, the Project design includes improvements that will result in increased travel options for people and changes in the current mode distribution. Improved mobility and transportation choices will result in benefits to people in local and regional communities. Specific benefits provided by the Project include the following:

- **Enhanced Transit and HOV** - The new bridge will provide for a dedicated transit/HOV lane in each direction, while relieving peak-period congestion for all traffic. These dedicated transit/HOV lanes between Bridgeport Road in Richmond and Highway 91 in Delta will support increased use of transit and ride-sharing. In addition, the Project design includes integrated transit stops at the Steveston Highway and Highway 17A interchanges and dedicated transit-only ramps at Bridgeport Road and Highway 17A that will improve the speed and reliability of transit trips. The new bridge will also be designed to accommodate future rapid transit.

- Enhanced pedestrian and cycling access - At present, cyclists and pedestrians are not permitted to use the Tunnel due to safety considerations. A shuttle service through the Tunnel is provided for these users, but operates only during limited hours. The new bridge will include multi-use pathways for pedestrians and cyclists, separated from the vehicle traffic lanes.
- The new multi-use pathways will enable pedestrians and cyclists to travel across the bridge, at all times, rather than having to rely on a periodic shuttle service. Pathways will connect to local walking/cycling routes on either side of the Fraser River including the Millennium Trail in Delta.
- In addition to cycling benefits associated with the new bridge, the Project will provide additional cycling improvements at a number of locations within the Highway 99 corridor to help address gaps in the current cycling network. These improvements will enhance connectivity within and between Richmond and Delta as well as important destinations like the BC Ferries Tsawwassen terminal and Vancouver International Airport to encourage commuter cycling as well as tourism and recreational cycling and walking.
- Improved cross-highway community connectivity and cohesion within communities - If the Tunnel is not replaced, peak period queues on local roads are forecast to grow in the future, with line-ups in Richmond extending along Steveston Highway and other South Richmond roads, as well as backing up along Highway 99. In Delta, Tunnel traffic delays would back up on River Road, Ladner Trunk Road, and other local roads as well as onto Highways 99, 17A and 17. The Project will significantly improve community connectivity across the highway in both Richmond and Delta.
 - In Richmond, the clearances underneath the new bridge, combined with the reconstruction and upgrading of the Steveston Highway overpass and the Westminster Highway overpass will result in improved connectivity between east and west Richmond and new access to/ from Rice Mill Road will improve access for commercial and industrial areas in South Richmond.
 - In Delta, the clearances under the new bridge will create opportunities for the Corporation of Delta to extend River Road helping to improve agricultural, road, and pathway connections across the highway. The new Highway 17A interchange will also improve access between North and South Delta.

1.1.11.3 Environmental

The Project is within an active transportation corridor that has been affected by past development and historic increases in traffic and congestion. The Project represents an opportunity to address current environmental challenges and enhance important environmental features.

Air quality and greenhouse gas emissions

In addition to the quantified user benefits realized through reduced fuel costs, the Project will also provide environmental benefits in terms of reduced greenhouse gas emissions (**Section 4.9 Air Quality**). A reduction in greenhouse gases will result from the combined effects of more fuel-efficient travel speeds and reduced idling associated with:

- Reducing congestion-related travel delay times
- Providing enhanced opportunities for alternate, less fuel intensive modes of transportation (i.e., transit, HOV, cycling, walking)

As discussed in (**Section 4.9 Air Quality**), relieving congestion at the Tunnel will provide benefits with respect to reducing idling-related emissions and result in an improvement in air quality over existing conditions as well as future conditions without the Project.

Habitat enhancement opportunities

The Project includes a number of opportunities for enhancing habitat values in the Project area including:

- Improvements to Deas Island Regional Park – the new bridge will result in enhancements to Deas Island Regional Park by improving the connection between the western and eastern portions of the park after the Tunnel portal is removed. The Project will restore the area under the new bridge with native vegetation and reconstruct marshlands, providing habitat improvements and connections for wildlife. Restoration of the shoreline of Deas Island also represents an opportunity to enhance fisheries values.
- Enhancing habitat values – Re-establishing drainage features parallel to Highway 99 provides an opportunity to enhance habitat values by ensuring the drainage features are designed to maximize habitat benefits.
- Green Slough – Relocating Green Slough back to its pre-Tunnel construction location, will result in benefits to fish and fish habitat by ensuring the design maximizes potential benefit to fisheries and wildlife.
- Improving water quality–Infrastructure to manage stormwater runoff from the road and bridge, including biofiltration ponds, will provide a benefit in terms of attenuating and treating flows before discharge to adjacent watercourses.

1.1.11.4 Health

Traffic safety

The Tunnel and adjacent interchanges have high collision rates. ICBC records indicate an average of 326 collisions annually at the Tunnel and adjacent interchanges between 2005 and 2013, of which approximately one-third involved an injury (B.C. MOTI 2015c).

The Project will result in significant traffic safety benefits, reducing collision rates by more than 35 per cent. This reduction is consistent with the actual traffic safety levels achieved at the new Port Mann Bridge. Overall, the traffic safety benefits resulting from the Project have a present value of \$135 million (Government of B.C. 2015d).

Seismic safety

The Tunnel, originally built to the standards of the 1950s, has been upgraded several times, including a structural strengthening program in 2006 to increase its resistance to failure in the event of an earthquake.

At present, a 1-in -275 year seismic event would lead to Tunnel failure - far below the current design standards of 1-in -2,475 years to be achieved with the new bridge. The seismic risk reduction benefit of the replacement bridge is estimated to have a present value of \$192 million in 2014 dollars (Government of B.C. 2015d).

Improved emergency response

Consultation with emergency responders during Project planning has clearly indicated that the current Tunnel presents challenges in providing emergency fire, police, and ambulance services both within the Tunnel itself and for across-the-river responses. By addressing existing congestion, the Project will result in improved emergency response capabilities and faster response times.

In addition, the Project will be designed to provide improved emergency vehicle access to incidents (e.g., providing better opportunities for police, fire, and ambulance vehicles to turn around and cross over lanes in emergency situations).

Human health benefits

As discussed in **Section 7.1 Human Health**, predicted decreases in vehicle emissions and general improvement in local and regional air quality are expected to result in human health benefits.

In addition to benefits to human health associated with improvements in air quality, the Project will result in broader human health benefits, including those associated with improved access to transit, cycling and walking infrastructure, as discussed in **Section 7.2 Health Impact Assessment**.

1.2 Applicable Authorizations

1.2.1 Provincial Permits and Approvals

This section of the Application identifies the provincial legislation and policies that apply to the Project and the provincial regulatory approvals that may be required following the issuance of an EAC and prior to commencement of Project construction, operation or decommissioning activities (see **Table 1.2-1**). The Ministry will not be requesting concurrent permitting for any of the authorizations under the Concurrent Approval Regulation.

Table 1.2-1 Potential Provincial and Federal Permits, Approvals, and Authorizations

| Name of Authorization | Statute and Authorizing Agency | Description of Need for Authorization |
|---|--------------------------------|---|
| Provincial | | |
| <i>Agricultural Land Commission Act</i> , S.B.C. 2002, c. 36 Agricultural Land Reserve Use, Subdivision and Procedure Regulation, B.C. Reg. 171/2002 Section 6, Permission for non-agricultural use | Agricultural Land Commission | New bridge and related highway corridor widening for new areas located within the Agricultural Land Reserve |
| <i>Environmental Management Act</i> , S.B.C 2003, c. 53 Contaminated Sites Regulation, B.C. Reg 375/96 | B.C. MOE | Soil or sediment requiring removal or offsite disposal during Project construction ² |
| <i>Heritage Conservation Act</i> , R.S.B.C. 1996, c. 187, s. 12 and s.14 Heritage Inspection Permit, Heritage Investigation Permit, or Site Alteration Permit | B.C. FLNR, Archaeology Branch | Heritage inspection, investigation, or site alteration of lands in the Project alignment |

² All material that contains potential contaminants in excess of the standards prescribed under section 7 of the CSR will be subject to a Contaminated Soil Relocation Agreement if they are to be moved offsite to locations other than approved landfills. Discharge of water generated during Project-related activities, such as dewatering or sediment removal, to the sanitary sewer may require a Metro Vancouver waste discharge permit.

| Name of Authorization | Statute and Authorizing Agency | Description of Need for Authorization |
|--|--|---|
| <i>Land Act</i> , R.S.B.C. 1996, c. 245 | B.C. FLNR | Tunnel decommissioning and construction of Project components on provincial Crown land |
| <i>Water Sustainability Act</i> , S.B.C. 2014, c. 15, Section 11 Water Sustainability Regulation, B.C. Reg. 36/2016, Parts 2 and 3 Change Approval (under Part 2 of the Regulation) or Notification (under Part 3 of the Regulation) for changes in and about a stream | B.C. FLNR | Activities in and about watercourses, including construction of the new bridge and approaches, and Tunnel decommissioning |
| <i>Wildlife Act</i> , R.S.B.C. 1996, c. 488 General Permit for wildlife relocation or salvage | B.C. FLNR | Relocation or salvage of wildlife within the Project alignment as required during Project construction |
| Federal | | |
| <i>Aeronautics Act</i> , R.S.C. 1985, c. A-2 Approval for construction of works in or near Canadian aerodromes | Transport Canada | Construction of the new bridge |
| <i>Canada Marine Act</i> , S.C. 1998, c. 10 VFPA Project Permit | VFPA Planning and Development Department | Decommissioning of the Tunnel and construction of Project components within VFPA navigational jurisdiction |
| <i>Fisheries Act</i> , R.S.C. 1985, c. F-14 S. 35(2)(b) Authorization | Fisheries and Canada | Tunnel decommissioning and other Project-related activities within the Fraser River |
| <i>Migratory Birds Convention Act, 1994</i> , S.C. 1994, c. 22 | Environment Canada | Construction of the new bridge, Tunnel decommissioning and other Project-related activities within the Fraser River |
| <i>Navigation Protection Act</i> , S.C. 2014 Permit or Approval | Transport Canada | Tunnel decommissioning, bridge clearance, and other Project-related activities within the Fraser River |
| <i>Species at Risk Act</i> , S.C. 2002, c. 29 Permit or Agreement | Environment Canada | Relocation or salvage of listed wildlife as needed during Project construction |

1.2.2 Federal Permits and Approvals

While the Project does not trigger a federal review under the *Canadian Environmental Assessment Act*, S.C. 2012, c.19, s. 52, federal involvement with the Project is anticipated to include requirement for issuance of a permit, approval or authorization from Department of Fisheries and Oceans (DFO), Environment Canada, TC, or VFPA. Federal legislation and regulatory approvals of relevance to the Project are identified in **Table 1.1-6**.

1.2.3 Other Requirements

The Project involves construction across railway tracks in three locations as identified in **Section 1.1.6.1**. Of these three locations, only the CN rail crossing at Rice Mill Road will result in a potential impact to existing rail infrastructure. The Ministry has and will continue to consult with CN regarding construction access at this crossing as Project planning proceeds. The agreement between the two parties related to construction access will become an order of the Canadian Transportation Agency and will allow the Ministry to undertake the Project according to agreed-upon terms.

In 2003, the Washington State Department of Ecology and the B.C. EAO signed a *Memorandum of Understanding* to facilitate information sharing and mutual understanding of EA/environmental review laws, and notification and information exchange on major project proposals. For the purposes of the agreement, a major project proposal in B.C. is considered to be in the vicinity of the State of Washington if it is located within 100 km of the international border. Given the location of the Project within 13 km of the Canada–U.S. border, the B.C. EAO will be responsible for notifying and providing Project-related information to the Washington State Department of Ecology.

1.3 Alternatives to the Proposed Project

This section presents an assessment of alternatives to the Project described in **Section 1.1**. The scope of the alternatives formally considered in this assessment was informed by the results of public consultation undertaken to confirm the Project need.

Public consultation identified transit-only alternatives for addressing the transportation challenges associated with the Tunnel. Based on this input, early engagement with TransLink, and preliminary analysis on alternatives, it was determined that a transit-only solution would be insufficient given the local, regional, provincial, and national importance of Highway 99 and the combined trip purpose/vehicle requirements/origins and destinations of existing traffic as well as planned future population and employment growth.

In response to interest in enhanced transit along the Highway 99 corridor, the Ministry worked with TransLink and area municipalities to identify transit improvements that could be incorporated into the Project to provide needed capacity improvements while also further encouraging alternatives to single occupancy vehicles. As such, the Project includes measures to promote mode shifts to transit, car-pooling, walking and cycling as alternatives to single occupant vehicles.

Improvements on opening day include dedicated transit/HOV lanes within the median for approximately 24 km in each direction, integrated transit stops within the Steveston and Highway 17A interchanges and a dedicated transit ramp at Bridgeport Road to highway 99, enabling direct transit access to and from the Canada Line at Bridgeport Station and a southbound transit ramp to Highway 17A that will improve the speed and reliability of transit trips. These measures will make transit more convenient and improve the reliability of transit travel times. Multi-use pathways on the bridge with connections to the existing trail and cycling network in Richmond and Delta will allow cyclists and pedestrians to freely cross the Fraser River at this location. The new bridge also will be built to accommodate potential future rapid transit.

1.4 Assessment of Project Alternatives

This section presents an analysis of feasible project options that were identified and considered during the planning phase of the Project, as alternative means to meeting the Project objectives. **Section 1.4.1** provides an overview of technical work undertaken to assess requirements for the number of lanes for the facility. **Section 1.4.2** provides an overview of the multiple accounts evaluation (MAE) conducted on alternative approaches.

1.4.1 Lane Requirements

A 10-lane bridge with one dedicated transit/HOV lane in each direction and four lanes for trucks and cars in each direction (a total of five lanes in each direction) would:

- Significantly reduce traffic collisions due to improvements in merging and reduced weaving.
- Eliminate congestion from opening day and accommodate future traffic growth, with no significant congestion to at least 2045.
- Eliminate the need for a counterflow operation.
- Provide a separate lane for trucks and other slower-moving traffic as they navigate the grade of the new bridge (similar to the Alex Fraser Bridge), without compromising travel times for faster-moving traffic.

- Potential to convert the transit/HOV lanes to rail rapid transit at some future point while retaining four lanes of capacity in each direction.
- Have a more favourable benefit-cost ratio, despite having a higher cost than an eight-lane crossing.

Operational modelling has shown that a 10-lane bridge provides proportionately greater benefits than an eight-lane bridge, which would have peak-period congestion on opening day. The 10-lane bridge provides a higher benefit-cost ratio despite the slightly higher cost, and would result in no significant change in total traffic volumes as compared with an eight-lane bridge.

Further details of the lane assessment are presented in George Massey Tunnel Replacement Project Traffic Data Overview Report (Government of B.C. 2015a).

1.4.2 Assessment of Alternatives

The information presented in this section summarizes the methodology and key conclusions of the evaluation of crossing scenarios presented in Evaluation of Crossing Options (MMK 2014) and includes:

- Description of crossing scenarios (alternatives) considered
- Evaluation methodology
- Identification of the preferred alternative

1.4.2.1 Identification of crossing alternatives considered

In 2012 the Ministry initiated consultation on the replacement of the George Massey Tunnel. The Phase 1 consultation process focused on understanding the project need, determining objectives, and developing the preliminary project scope and design requirements.

As a result of this consultative process, six Project goals were identified as outlined in **Section 1.1.1**.

The results of this phase of consultation were used to inform Phase 2 Consultation, undertaken in 2013, which focused on considering the following five alternatives, referred to as scenarios in the MAE, that were developed as a result of consultation input and technical analysis:

- 1) Maintain existing Tunnel: Rehabilitate the Tunnel's mechanical systems, improve its ability to withstand future earthquakes (although not to new-construction standards), and make improvements to the existing interchanges at Steveston (to the north) and Highway 17A (to the south).

- 2) Replace existing Tunnel with new bridge: Construct a new bridge along the existing right-of-way, after which the Tunnel would be decommissioned.
- 3) Replace existing Tunnel with new Tunnel: Construct a replacement Tunnel along the existing right-of-way, likely upstream from the existing Tunnel, after which the existing Tunnel would be decommissioned.
- 4) Maintain existing Tunnel and build new crossing along existing Highway 99 Corridor: The new crossing could be either a bridge or Tunnel.
- 5) Maintain existing Tunnel and build new crossing in a new corridor. The new crossing would be a bridge located between the existing Tunnel and the Alex Fraser Bridge, and accessed via the South Fraser Perimeter Road on the south side and via a newly constructed connection to Highway 91 on the north side.

1.4.2.2 Evaluation Methodology

The evaluation methodology that was used to consider the five project alternatives noted above, incorporated a multiple accounts evaluation (MAE) framework that included specific criteria, grouped under six categories as below:

- 1) Efficient transportation for all users – traffic congestion; transit capability; travel time reliability; and pedestrian and cycling accessibility.
- 2) Safety – incident response capability; earthquake protection; and traffic safety.
- 3) Agriculture – agricultural land effects; and access to/from agricultural areas.
- 4) Environment – local and regional air quality; wildlife and terrestrial habitat; and marine life and habitat.
- 5) Jobs and the economy – access to gateways and trade corridors; access to business and industrial land; and marine access for goods movement.
- 6) Social and community considerations – community access (including across the highway within communities); private property effects; noise effects; and visual effects.

In addition to the evaluation criteria identified during Phase 2, capital costs and risks were included in the analysis. This resulted in a total of 28 individual criteria within seven major categories (**Table 1.4-1**). Most of the evaluations were performed on a four-point scale, based on the degree to which each scenario is assessed as potentially achieving the relevant project goals, relative to the other scenarios. Capital and O&M costs were compared on a three-point scale, since the scenarios are high-level concepts for which detailed cost information was not available at the time of the evaluation. The individual assessments, and the overall comparison of scenarios, represent the combined results of preliminary planning and technical work undertaken by the Ministry and its engineering, environmental, and economic/financial advisors, as well as the public feedback and input received through the Phase 1 and Phase 2 consultation and review processes.

Table 1.4-1 MAE Assessment of Project Alternatives

| Evaluation Area | Specific Criterion | Alternative | | | | |
|-------------------------------------|--|--------------------|-----------------------|-----------------------|--|---|

Selection of the preferred alternative

As summarized on **Table 1.4-2**, Alternative 2 (Replacement Bridge) was identified as the superior alternative. Its overall rating was similar to or preferred to the four other alternatives in each evaluation area. The comparative ratings for Alternative 2 for each evaluation area, are as follows:

- **Transportation efficiency** – Benefits in terms of congestion relief, transit capability, and travel time reliability, associated with Alternative 2, are similar to those of Alternatives 3 and 4, greater than those of Alternative 5, and much greater than those of Alternative 1. Alternative 2 is also preferable (along with the Alternative 4 bridge option) in terms of the potential to improve pedestrian and cyclist accessibility.
- **Safety** – Alternatives 2 and 3 are preferable in terms of both traffic safety and seismic (earthquake) safety. An all-new crossing would be designed to significantly higher standards than what is achievable through maintaining the existing Tunnel.
- **Agriculture** – Alternative 2 is preferable to all other alternatives in improving the connectivity between agricultural areas on either side of the corridor, because of the ability to provide access underneath the bridge for agricultural traffic. Alternative 2 would require more properties to be acquired than Alternative 1, where acquisition requirements would be minimal.
- **Environment** – Alternative 2 is preferable or similar to all other alternatives in terms of marine and aquatic biota, wildlife, shorelines, habitat, and regional air quality. Under Alternative 2, bridge piers can be situated outside of the river, while all other alternatives would involve significant in-river disturbance. Alternative 2 is also preferable to all other alternatives in terms of local air quality, because particulates can naturally disperse in the open air, minimizing local concentrations.
- **Jobs and the economy** – Alternative 2 is considered to provide longer-term employment and economic benefits relative to Alternative 1, and is similar to or higher than every other alternative. Alternative 2 would also have the least effect on marine traffic during construction.
- **Social and community considerations** – Alternative 2 has the greatest ability to improve access across the highway between communities, because of the potential for local road connections underneath the bridge abutments on either side of the crossing. Alternative 2 also provides the capacity to serve the existing and future transportation needs of the population targets for the adjacent communities (Richmond, Delta, Tsawwassen, Surrey, White Rock) established by Metro Vancouver's RGS (2015). Alternative 2 would introduce new above-ground visual and noise effects at the existing crossing that would require mitigation.

A detailed description of the analysis of each alternative, is presented in George Massey Tunnel Replacement Project Evaluation of Crossing Options (MMK 2014).

The results of the evaluation of the remaining alternatives was as follows:

Alternative 1 – Maintaining the Tunnel

The evaluation of maintaining the Tunnel indicated that, even with investments to address seismic resistance and rehabilitate aging internal infrastructure, this alternative would not contribute to achieving most of the Project objectives including primary objectives related to transportation efficiency (i.e., congestion, travel time reliability, pedestrian and cyclist access etc.). Maintaining the existing Tunnel would also not provide for improved access to agriculture nor provide benefits with respect to improved access within and across communities or support community and regional planning objectives.

While upgrades to the infrastructure associated with this alternative would reduce seismic risk, the rehabilitated infrastructure would not meet current seismic standards and the existing traffic safety issues associated with the lower design standards (i.e., lane widths and clearances) would remain. Tunnel rehabilitation would also result in substantially greater construction effects on marine users and river-associated environmental values. In addition, while maintaining the Tunnel would have the lowest capital construction costs it would not contribute to achieving the employment and economic objectives of the Project and would have the highest capital cost risk associated with works required to address the current seismic issues.

Alternative 3 – Replacement Tunnel

While replacing of the Tunnel with a new tunnel would meet many of the transportation and safety objectives of the Project, construction works associated with building a new tunnel would have substantially larger effects on marine users, fisheries and habitat values and agricultural land requirements. In addition, local air quality that is influenced by the concentration of vehicle emissions at the tunnel portals would not be addressed. While estimated capital costs for building a replacement tunnel would be similar to the proposed Project, there would be substantial risk associated with building in proximity to the existing Tunnel.

Alternative 4 – Maintain Tunnel/New crossing in 99 corridor

Maintaining and rehabilitating the Tunnel and adding a new crossing in the Highway 99 corridor would meet many of the transportation efficiency objectives of the Project as well as social and community considerations. However, safety objectives of the Project, including incident response, earthquake protection and traffic safety, would not be fully achieved. Rehabilitating the Tunnel would also result in greater effects to marine users and in-river environmental values during construction, as is the case in Alternative 1. Maintaining the Tunnel would also not result in improvements to local air quality as the concentration of air emissions at the Tunnel portals would remain.

In addition to the challenges associated with maintaining the Tunnel, construction of a new bridge crossing in the Highway 99 corridor would require an offset from the alignment of the Tunnel resulting in greater effects on agricultural land required for the bridge approaches. The combination of rehabilitating and maintaining the Tunnel and building a new bridge crossing also results in amongst the highest operation and maintenance costs and substantial risk during construction

Alternative 5 - Maintain existing Tunnel/new crossing in new corridor

Maintaining and rehabilitating the Tunnel and adding a new bridge crossing in a new corridor would meet some of the transportation efficiency objectives of the Project though would not address pedestrian and cycling access or seismic considerations. The requirement for a new corridor associated with Alternative 5 would result in the greatest effects on agriculture and the environment as well as substantial socio-community effects including noise issues. Establishing a new corridor would also result in the greatest capital construction costs as a result of the requirement to acquire land.

As with other alternatives involving retention of the Tunnel, safety objectives of the Project, including incident response, earthquake protection and traffic safety would not be achieved. Rehabilitating the Tunnel would also result in substantial effects to marine users and in-river environmental values during construction and would not address local air quality concerns associated with the concentration of air emissions at the Tunnel portals. The combination of maintaining the existing Tunnel and establishing a new corridor would result in the highest capital construction costs and risk as well as high operating and maintenance costs.

Table 1.4-2 Summary comparison of project alternatives

| Evaluation Area | Alternative | | | | |
|-------------------------------------|--------------------|-----------------------|-----------------------|--|---|
| | 1. Maintain Tunnel | 2. Replacement Bridge | 3. Replacement Tunnel | 4. Maintain Tunnel, Add In-Corridor Crossing | 5. Maintain Tunnel, Add New-Corridor Crossing |
| Transportation efficiency | xx | ✓✓ | ✓✓ | ✓✓ | ✓ |
| Safety | xx | ✓✓ | ✓✓ | ✓ | ✓ |

Notes: ✓✓ very high achievement of goals; ✓ relatively high achievement of goals; x relatively limited achievement of goals; xx low/no achievement of goals. Retrieved from George Massey Tunnel Replacement Project - Evaluation of Crossing Scenarios (MMK 2014).

Financial costs and risks

The capital costs associated with Alternative 2 are expected to be similar to those of Alternatives 3 and 4, and to be significantly lower than those of Alternative 5. While capital costs are much higher for Alternative 2 than Alternative 1, Alternative 1 does not achieve the Project’s key safety and congestion relief goals, and is only a medium term option due to the existing Tunnel’s age and condition. With regard to risks, Alternative 2 is assessed as having lower risks during both construction and operation than any other alternative, due to (a) avoiding the need to undertake seismic improvements to the existing Tunnel that would be required under Alternatives 1, 4 and 5, and (b) avoiding the significant in-river work that would be required under Alternative 3.

2.0 Environmental Assessment Process

2.1 Provincial EA Process

On December 16, 2015, the Environmental Assessment Office (EAO) issued a section 10 Order confirming that the Project is a reviewable project pursuant to the B.C. Environmental Assessment Act (*EAA*), and that it requires an EAC. On March 7, 2016, EAO issued a section 11 Order which outlines the scope, procedures and methods for the environmental assessment of the Project. The section 10 and 11 Orders are available on EAO's website (https://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_project_home_430.html).

This section describes the regulatory context for the proposed George Massey Tunnel Replacement Project (Project), the need for an environmental assessment (EA), and the key EA process milestones.

This section provides an overview of participation from Aboriginal Groups, the public, and government agencies in the Project's EA prior to and during the pre-Application stage. More detail, including information on consultation planned during the Application Review stage is provided in **Section 10 Aboriginal Consultation** and **Section 11 Public Consultation** of the Application.

2.1.1 Regulatory Context

2.1.1.1 Project Triggers under B.C. *EAA*

The Project was deemed reviewable by EAO under section 10(1)(c) of the B.C. *EAA* on December 16, 2015. The Project constitutes a reviewable project pursuant to Part 5 of the Reviewable Projects Regulation (B.C. Reg. 370/02), as it involves a dismantling or abandonment of an existing shoreline modification facility that, if it were a new facility, would entail dredging, filling, or other direct physical disturbance of equal to or greater than 2 ha of foreshore or submerged land, or a combination of foreshore and submerged land, below the natural boundary of an estuary. It also constitutes a reviewable project pursuant to Part 8, as it involves a modification of an existing public highway that results in the addition of equal to or greater than 2 lanes of paved public highway to an existing paved public highway over a continuous distance of equal to or greater than 20 km. As a reviewable project, the Project requires an EAC before provincial agencies can issue other necessary approvals required to start construction.

2.1.1.2 Application Development

The Application has been developed pursuant to the Application Information Requirements (AIR) that EAO approved on May 24, 2016 and complies with relevant instructions provided in the section 11 Order issued on March 7, 2016.

2.1.2 Key EA Process Milestones

Table 2.1-1 documents the Project’s key EA process milestones.

Table 2.1-1 Key EA Process Milestones for the Project

| Key Milestones | Date |
|--|---------------------------------|
| EAO Issued Documents | |
| Section 10 Order Available online on EAO Project Information Centre (e-PIC): https://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39645.html | December 16, 2015 |
| Section 11 Order Available online on e-PIC: https://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39946.html | March 7, 2016 |

| Open houses | January 26/27, 2016 |

2.1.3 Aboriginal Groups Participation

This section provides an overview of the consultation activities undertaken before and during the Project's pre-Application stage with Aboriginal Groups potentially affected by the Project, as identified in the section 11 Order, and as outlined in the Aboriginal Consultation Plan. Additional information is provided in **Section 10 Aboriginal Consultation**.

The Ministry is committed to ongoing consultation and engagement with Aboriginal Groups. The Aboriginal Consultation Plan and the Aboriginal Consultation Report describe the consultation activities the Ministry has and will undertake during the pre-Application, Application, and post-Application phases of the EA to satisfy the requirements of the section 11 Order.

2.1.3.1 List of Aboriginal Groups that Participated in the EA

The following Aboriginal Groups, as set out in the section 11 Order, have participated in the EA and were invited to participate in EAO's Technical Working Group:

- Cowichan Tribes
- Halalt First Nation
- Katzie First Nation
- Kwantlen First Nation
- Lake Cowichan First Nation
- Lyackson First Nation
- Musqueam Indian Band
- Penelakut First Nation
 - Hwlitsum¹
- Semiahmoo First Nation
- Squamish Nation
- Stz'uminus First Nation
- Tsawwassen First Nation
- Tseil-Waututh Nation

In accordance with the section 11 Order, notification of the Project and the Technical Working Group process has been sent to People of the River Referrals Office.

¹ This reference to the Hwlitsum is not intended to signify any change in the position that the Province may have taken in other contexts in relation to the duty to consult with this group.

2.1.3.2 Summary of Aboriginal Group Participation

Initial Consultation

The Ministry recognizes the importance and value of early engagement with the Aboriginal Groups that have Aboriginal Interests within the Project area, and undertook an Initial Consultation Phase prior to the pre-Application phase. The Ministry consulted with all of the Aboriginal Groups later assigned to Schedule B of the section 11 Order. During the Initial Consultation Phase, the Ministry also offered to meet with the Stō:Lò Nation and Stō:Lò Tribal Council and received a deferral from the People of the River Office (representing member communities of the Stō:Lò Nation and Tribal Council) in May 2014. In January 2016, PRRO advised EAO of their interest in deeper consultation given the decommissioning of the Tunnel component of the Project including the removal of sections of the Tunnel. As a result, EAO added PRRO to Schedule C of the Section 11 Order in March 2016.

At meetings with Aboriginal Groups, the Ministry provided introductory information regarding the Project scope and schedule, sought input with respect to Aboriginal Groups' current use of the Project alignment for traditional purposes and obtained information on concerns related to potential impacts on Aboriginal interests. The Ministry also sought to determine community-specific preferences with respect to participation in Project consultation, EA review, and related activities. During this phase of consultation, communications protocols were established and key contacts were identified and/or confirmed.

Pre-Application Phase Consultation

The Ministry consulted with all Schedule B Aboriginal Groups during the Pre-Application Phase. In addition to meetings with Chief and Council and/or Aboriginal Groups' staff, the Ministry also facilitated site visits and community meetings; facilitated participation of Aboriginal Groups' representatives in fieldwork; and participated in two, EAO led, Technical Working Group meetings.

During this phase, the Ministry sought input into key Project and EA planning documents. Schedule B Aboriginal Groups were provided funding for Traditional Use or other Project related studies.

2.1.3.3 Key Issues Raised

The Ministry maintains an Aboriginal Group consultation record to track communication and consultation activities. A high-level overview of the key issues raised by Aboriginal Groups during the Initial and pre-Application consultation phases is provided below. A detailed breakdown of issues identified by individual Aboriginal Groups, and the status of those issues is presented in **Appendix B of Section 10 Aboriginal Consultation**.

The key issues raised during pre-Application consultation included:

- Environmental Assessment Process
- Potential effects to Aboriginal Interests (fishing, harvesting, cultural and social resources, trade, land use, marine navigation and knowledge transfer)
- Consultation and engagement
- Participation in Project
- Cumulative effects
- Accidents and Malfunctions
- Tolling
- Traffic
- Potential Project-related effects to:
 - Air Quality
 - Archaeology and heritage resources
 - Atmospheric noise
 - Contaminated sites
 - Fish and fish habitat
 - Human health
 - Marine use
 - River hydraulics
 - Terrestrial Wildlife
 - Water quality and sediment

Feedback received from Aboriginal Groups has helped in developing the avoidance, mitigation, and management strategies for the Project. A description of the Ministry's procedures for tracking and reporting on information received from Aboriginal Group consultation is provided in **Section 10 Aboriginal Consultation**. For a complete summary of key issues raised and status of resolution, please refer to **Appendix B in Section 10 Aboriginal Consultation**. The Ministry is committed to ongoing consultation and engagement with Aboriginal Groups. As described in the Aboriginal Consultation Plan, consultation and engagement will continue through the Application review and post-Application stages.

Table 2.1-2 Summary and Status of Key Issues Raised by Aboriginal Groups

| Issue Raised | EA Section Reference/Status |
|--|--|
| Environmental Assessment Process and consultation process | The environmental assessment process is discussed in this section, and more specifically focused to Aboriginal Groups in Section 10.0 Aboriginal Consultation . |
| Potential Project-related effects to Aboriginal Interests | Historical and current Aboriginal Interests and the potential interactions of the Project on Aboriginal Interests are discussed in Section 10.0 Aboriginal Consultation . |
| Aboriginal Participation and Project Related Opportunities | Aboriginal participation in the Project is discussed in this section and in more detail in Section 10.0 Aboriginal Consultation |
| Cumulative Effects | Applicable projects and the methodology undertaken to assess cumulative effects are discussed in Section 3.0 Methodology . |
| Potential accidents or spills during Project construction | Potential Project-related construction or operation phase accidents or malfunctions are discussed in Section 8.0, Accidents and Malfunctions |
| Changes in air quality as a result of the Project | Potential changes in air quality as a result of the project are discussed in Section 4.9 Air Quality |
| Potential effects to archaeology and heritage resources within the Project area | Archaeological and heritage resources have been assessed and are discussed in Section 6.1 Heritage and in Section 10.0 Aboriginal Consultation |
| Potential increased atmospheric noise during Project construction | Potential changes in atmospheric noise as a result of construction and operation of the project are discussed in Section 4.10 Noise |
| Potential Project-related effects to fish and fish habitat | Section 4.4 Fish and Fish Habitat |
| Potential Project-related effects to health | The potential for the Project to effect health is discussed in Section 7.0 Human Health |
| Potential disruptions to marine use affecting Aboriginal use of the Project area | Potential Project-related changes to commercial, recreational, and Aboriginal navigation and fishing activities during construction or operation are discussed in Section 5.2 Marine Use and in Section 10 Aboriginal Consultation |
| Potential changes in riverbed during and following Tunnel removal | Potential changes to river hydrology and morphology during and after Tunnel removal are discussed in Section 4.1 River Hydraulics and River Morphology |

| Issue Raised | EA Section Reference/Status |
|---|--|
| Potential Project-related effects to terrestrial wildlife or wildlife habitat | Existing habitat, wildlife species known to be present, and potential Project-related effects to wildlife or wildlife habitat are discussed in Section 4.8 Wildlife |
| Changes in traffic during and after Project construction | Existing traffic and the anticipated changes in traffic during construction and operation for the Project are discussed in Section 5.1 Traffic . |
| Culturally and ecologically sensitive ecosystems within the Project area | Sensitive ecosystems within the Project area have been identified. The potential for the Project to effect sensitive ecosystems and proposed mitigation are discussed in Section 4.7 Vegetation |
| Potential changes in water quality due to Project construction and operation | Potential Project-related effects to water quality during construction and operation are discussed in Section 4.2 Water Quality |

2.1.4 Public Participation

This section provides an overview of the consultation activities undertaken during the Project’s pre-Application stage with the public and stakeholders. References to “public and stakeholders” include any individuals with an interest in the Project who have not been identified as members of involved Aboriginal Groups or representatives of government agencies. Public and stakeholder participation for the Project has been guided by the Ministry’s Public Consultation Plan, which is available on EAO’s website for the Project. Additional information is provided in **Section 11.0 Public Consultation**. The Public Consultation Plan, and the Public Consultation Report describe the public consultation activities the Ministry has and will undertake during the pre-Application, Application, and post-Application phases of the EA to satisfy the requirements of the section 11 Order issued for the Project.

Public participation to date has included: a wide variety of stakeholders representing a breadth of interests including local residents; businesses and property owners; people who have visited, called, or e-mailed the Project’s Information Office; presentations and meetings with community and business groups and private individuals; cycling advocacy groups; commercial and recreational marine users; environmental groups; and others enquiring about the Project. Consultation has included formal meetings and open house events as well as informal community relations activities. More information on comments received during the pre-Application consultation phase is provided in **Section 11.0**.

2.1.4.1 Summary of Public Participation

Since announcement of the Project in September 2012, the Ministry has been providing information about the Project, engaging stakeholders and interested parties in dialogue, and responding to Project-related enquiries. Key outreach activities conducted before and during the pre-Application phase are described below.

Public Consultation

The Ministry undertook three phases of consultation for the Project leading to the EA process. Each phase included open houses with display boards, discussion guides, and feedback forms, and provided participants with an opportunity to speak with Project staff. All consultation materials were made available online at masseytunnel.ca during and after each consultation event, and all events were advertised through print newspapers, on the Project website, through the Project e-database (see “Project Office” section, below), and through media releases that often generated news stories. Following each consultation event or series of events, a Consultation Summary Report was prepared, documenting the input received.

- **Phase 1: Understanding the Need** (November to December 2012) – Conducted early in the Project’s planning process, this phase of consultation sought input to gain a better understanding of travel demand, operating conditions, and opinions and interests on the importance of various design considerations.
 - A total of 1,150 people participated in this phase of consultation. Congestion relief and economic growth were identified as the most important factors when considering solutions for the Tunnel. Doing nothing was not viewed as an option. Participants noted the importance of considering all users, including drivers, goods movers, transit riders, cyclists, and pedestrians. Participants were also interested in short-term solutions while planning for a long-term solution continued.
- **Phase 2: Exploring the Options** (March to April 2013) – Sought input on five potential tunnel replacement scenarios and the criteria to evaluate these scenarios.
 - More than 1,000 people participated. Participants expressed general support for Project goals and evaluation criteria. There was also an overall preference for a new bridge on the existing corridor (Scenario 2), with polarized views on the other scenarios, particularly, maintaining and upgrading the Tunnel (Scenario 1), and constructing a new crossing along a new corridor to the east (Scenario 5). Participants also expressed questions and concerns about the safety of tunnels and a desire for plans to allow for future rapid transit. Participants also requested more information about cost and funding options.

- **Phase 3: Project Definition Report** (December 2015/January 2016) sought input on the Project Definition Report (<http://engage.gov.bc.ca/masseytunnel/files/2015/12/GMT-Project-Definition-Report-Dec-2015.pdf>) including the proposed Project scope, Project success measures, funding options, and traffic management during construction. This input assisted in finalizing the EA Application and also will be used to finalize the Project scope and cost estimate. Results can be viewed in the Phase 3 Consultation Summary Report (<http://engage.gov.bc.ca/masseytunnel/files/2016/04/Phase-3-Consultation-Summary-Report-March-2016.pdf>).
 - More than 1,035 people participated, including 750 who attended the open houses, which were held concurrent with open houses for the pre-Application Public Comment Period (see below). Participants expressed continued support for the Project overall and interest in more detail about specific elements including interchange designs, traffic forecasts, and the upcoming environmental assessment. There was also strong support for capacity improvements to address congestion and proposed transit, cycling and pedestrian measures. Most participants who commented about tolls supported tolling as a funding mechanism; however, many participants suggested that tolling should be applied in the context of a regional tolling policy.

As part of the pre-Application consultation for the Project, the EAO held a public comment period. The public comment period included open houses with display boards, audio/visual displays, discussion guides, and feedback forms, and provided participants with an opportunity to speak with EAO staff and Project staff. All consultation materials were made available online at masseytunnel.ca during and after each consultation event, and all events were advertised through print newspapers, on the EAO and Project websites, through the Project e-database (see “Project Office” section, below), and through media releases that often resulted in news stories.

- **Pre-Application Public Comment Period** (January 15 – February 15, 2016) – sought input on the Project Description and Key Areas of Study document for the Project. Two open houses, led by EAO, were held in support of the 31-day public comment period (January 26 and January 27, 2016).
 - A total of 750 people attended the open houses (held concurrent with the open houses held for the PDR) and EAO received 450 public submissions. All EAO submissions were posted to EAO’s electronic Project Information Centre (ePIC) within seven days of the comment being received by EAO.

The key themes from Project representatives’ discussions with members of the public at the Open Houses, written comments received during the 31-day review period and ongoing consultation with stakeholders are provided in **Section 11.0 Public Consultation** of this Application.

Project Office

A Project website (www.masseytunnel.ca) was established in November 2012 to provide information about the Project, including historical information and reports; current Project status; Project-generated reports and information including consultation materials; answers to frequently asked questions; how to contact the Ministry; and an option to subscribe to the Project e-database for Project updates by e-mail. In addition, the Project works with the Ministry's social media team to incorporate Project updates into the Ministry's @TRANBC Twitter feed.

A Project-related electronic database (e-database) was established in November 2012 enabling people to sign up and receive e-mails about the Project. The database now has more than 1,800 subscribers.

Also established in November 2012, a Project information telephone line (1-855-MASSEY) and e-mail address (masseytunnel@gov.bc.ca) enables one-to-one correspondence and direct replies to enquiries. A goal of initial response within two business days was established.

A Project Office in Richmond was opened in January 2014. The Project Office has two full-time community relations staff who provide Project information to the public; and manage the website, the information telephone line, and the e-database. The office includes information display boards, access to the Project website, and fly-through animation of the Project corridor. To date (up to 15 May 2016) more than 4,000 people have visited the Project office.

Community Outreach

The Ministry has engaged in a variety of additional outreach activities as described below:

- **Presentations on request** to a variety of business and community groups. More than 100 presentations have been made to date including:
 - Community and recreational clubs and organizations
 - Boards of Trade and Chambers of Commerce
 - Business clubs and associations
 - Professional organizations
 - Metro Vancouver planning, transportation, and engineering symposia

- **Meetings with key stakeholder groups** to gather input in support of developing conceptual designs for the new crossing. Since 2012, the Ministry has:
 - Consulted extensively with stakeholder groups including agricultural organizations, business organizations, commercial and recreational and commercial marine users, community and resident groups, recreational groups, and first responders
 - Attended a variety of community events with the Delta and Richmond Chambers of Commerce

Advertising and Media Relations

The Ministry maintains an ongoing and open dialogue with the media. Since November 2012, numerous stories have been published on the Project, including interviews with the Minister of Transportation and Infrastructure, the Executive Project Director, and other Project spokespersons. Highlights include:

- More than 750 directly related articles have been published in local and regional newspapers, primarily the Vancouver Sun, the Province, the Delta Optimist, South Delta Leader, Richmond News, and the Globe and Mail.
- Notification for each phase of consultation has been advertised in local and regional newspapers.

2.1.4.2 List of Key Issues Raised and Status of Resolution

Table 2.1-3 summarizes key issues raised as a result of public and stakeholder consultation and engagement to date, and the status of the issue. Detailed results, including more information on issues raised and status or resolution are presented in **Table 11.2-3; Section 11.0 Public Consultation.**

Table 2.1-3 Summary and status of Key Issues Raised by Public during pre-Application Consultation

| Key Issue Raised | Section Reference/ Status |
|--|---|
| Transit/Project Alternatives | Alternatives to the Project that were assessed are discussed in Section 1.3 Project Design and/or Alternative Means of Carrying out the Project. |
| Potential loss of agricultural land | Section 5.4 Agricultural Use describes potential changes to the boundaries of a small number of farms and the mitigation to be applied to minimize land requirements, as well as offsetting opportunities. |
| Potential changes in air quality and greenhouse gas emissions | Potential Project-related changes to air quality and greenhouse gas are discussed in Section 4.9 Air Quality. |
| Changes in traffic as a result of the Project | Section 5.1 Traffic discusses the anticipated changes in traffic, including expected improvements of the Project on traffic within the highway 99 corridor. |
| Tolling | Tolling is discussed in Section 1.1 Description of Proposed Project. |
| Effects of Tunnel removal on salinity and irrigation intake | Salinity in the context of irrigation intake is discussed in Section 4.1 River Hydraulics and River Morphology and Section 5.5 Agricultural Use. |
| Effects of changes in noise for residential areas near the new bridge | Potential Project-related changes in atmospheric noise and effects to residential areas is discussed in Section 4.10 Atmospheric Noise. |
| Effects of visual changes for residential areas near the new bridge | Section 5.5 Visual Quality describes the changes in viewsapes that would be expected as a result of the new bridge. Photos showing existing conditions and renderings with the anticipated new viewsapes are included. |
| Effects of wildlife and fish and fish habitat associated with the Fraser River | Potential Project-related effects to fish and fish habitat are discussed in Section 4.4, Fish and Fish Habitat ; potential Project-related effects to wildlife are discussed in Section 4.5 At-Risk Amphibians, Section 4.6 Marine Mammals, and Section 4.8 Terrestrial Wildlife. |
| Consultation process | The public consultation process is discussed in this section and in more detail in Section 11.0 Public Consultation. |
| Project Cost | Project cost and benefits is discussed in Section 1.1 Description of Proposed Project |

2.1.5 Government Agency Participation

2.1.5.1 List of Government Agencies that Participated in the EA

Consultation was initiated by the Ministry in 2012 and has been ongoing throughout the Project's pre-Application stage.

The Project team has consulted with the regulatory and non-regulatory agencies identified below.

Regulatory Agencies:

- Provincial:
 - Agricultural Land Commission
 - B.C. Environmental Assessment Office
 - B.C. Ministry of Environment
 - B.C. Ministry of Forests, Lands, and Natural Resource Operations
 - B.C. Ministry of Transportation and Infrastructure
- Federal
 - Canadian Environmental Assessment Agency
 - Environment and Climate Change Canada
 - Fisheries and Oceans Canada
 - Transport Canada
 - Port of Vancouver

Municipal and Regional Agencies:

- Local Governments and Organizations
 - City of Richmond
 - City of Surrey
 - City of Vancouver
 - City of White Rock
 - Corporation of Delta
 - Fraser Health Authority
 - Metro Vancouver
 - TransLink
 - Tsawwassen First Nation
 - Vancouver Coastal Health Authority

2.1.5.2 Technical Working Group

A key component of agency participation has been the establishment of the Technical Working Group. The purpose of the Technical Working Group is to provide advice and input on aspects of the environmental assessment. Consultation with the Technical Working Group, and other agencies, will continue through the Application review stage and future Project phases.

The Technical Working Group is comprised of Aboriginal Groups identified in Schedule B of the section 11 Order and the following government agencies:

- Provincial Agencies:
 - Agricultural Land Commission
 - B.C. Environmental Assessment Office
 - B.C. Ministry of Environment
 - B.C. Ministry of Forests, Lands, and Natural Resource Operations
 - B.C. Ministry of Transportation and Infrastructure
- Federal Agencies:
 - Environment and Climate Change Canada
 - Port of Vancouver
 - Transport Canada
- Municipal and Regional Agencies:
 - City of Richmond
 - Corporation of Delta
 - Fraser Health Authority
 - Metro Vancouver
 - TransLink
 - Vancouver Coastal Health Authority

2.1.5.3 Summary of Government Agency Participation

Since the Project was announced in September 2012, the Project team has been working to raise awareness, engage interested parties in dialogue about the Project, and respond to enquiries.

Introductory meetings were held with local governments including the Corporation of Delta, City of Richmond, City of Surrey, City of Vancouver, TransLink, Metro Vancouver staff and the Agricultural Land Commission in fall 2012, prior to the start of public consultation.

Regular meetings with Delta (approximately every two weeks), Richmond (approximately every two weeks) and Metro Vancouver (approximately every six weeks) staff have been ongoing since 2013. The Ministry has participated in more than 85 meetings with City of Richmond staff, more than 85 meetings with Corporation of Delta staff and more than 30 meetings with Metro Vancouver staff. Meetings with Surrey, White Rock, and TransLink have also been ongoing. The purpose of these meetings has been to identify local government interests, concerns about potential Project-related effects, and opportunities to address issues through improvements and/or mitigation strategies. Engagement with these groups is ongoing.

The Ministry has also engaged with municipal, provincial, and federal elected officials through informal meetings and formal presentations.

As part of the overall engagement strategy, the Ministry undertook the following consultation activities with government agencies during the pre-Application phase:

- Engaged with the EAO Technical Working Group to exchange information and respond to questions and comments on the Project Description and Key Areas of Study and the AIR
- Continued to meet with Delta, Richmond, Metro Vancouver, and TransLink staff to refine traffic modelling
- Identified and documented questions, issues, and interests raised
- Identified measures to avoid or mitigate potential adverse effects
- Attended supplemental and/or sub-committee Technical Working Group meetings as appropriate for matters requiring more detailed or agency-specific discussion
- Maintained an issues tracking database, including provision of frequent status updates, to show how the Project team is appropriately responding to the issues raised by Technical Working Group members

Consultation planned during the Application and post-Application phases are described in **Section 11.0** and in the Public Consultation Plan.

2.1.5.4 List and Status of Key Issues Raised

Key issues that have arisen in consultation and engagement with government agencies conducted to date and the status of the issues are summarized in **Table 2.1-4**.

Table 2.1-4 Summary and status of Key Issues Raised by Government Agencies

| Issue Raised | EA Section Reference/Status |
|---|---|
| Potential Project-related effects on environmentally sensitive areas including wetlands | Section 4.7 Vegetation identifies sensitive ecosystems within the vicinity of the Project and describes mitigation measures to minimize of off-set potential effects. |
| Occurrence of species at risk within the Project area | Potential and known occurrences of species at risk within the Project area are discussed in Section 4.5 At-risk Amphibians , Section 4.7 Vegetation and Section 4.8 Terrestrial Wildlife . |
| Potential effects to wildlife within Deas Island Regional Park | Wildlife and wildlife habitat within Deas Island Regional Park is identified and discussed in Section 4.8 Wildlife . |
| Changes in traffic as a result of the Project | Section 5.1 Traffic discusses the anticipated changes in traffic, including expected improvements of the Project on traffic within the highway 99 corridor. |
| Potential effects on commercial, recreational and aboriginal navigation | Section 5.2 Marine Use discusses commercial, recreational, and Aboriginal navigation and the potential effects of the Project on navigation during construction and operation. |
| Potential effects on recreational use within Deas Island Regional Park | Section 5.3 Land Use discusses recreational activities within Deas Island Regional Park and Section 5.2 Marine Use discusses recreational activities within Deas Slough. |
| Potential loss of agricultural land | Section 5.4 Agricultural Use describes potential changes to the boundaries of a small number of farms and the mitigation to be applied to minimize land requirements, as well as offsetting opportunities. |
| Change in viewsapes resulting from the bridge | Section 5.5 Visual Quality describes the changes in viewsapes that would be expected as a result of the new bridge. Photos showing existing conditions and renderings with the anticipated new viewsapes are included. |
| Potential effects of the project on human health | Section 7.0 Health assesses the potential changes in human health as a result of Project-related changes. |

Part B – Assessment of Environmental, Economic, Social, Heritage and Health Effects

3.0 Assessment Methodology

The methods for assessing the environmental, economic, social, heritage, and health effects (referred to as pillars by the Environmental Assessment Office) of the Project were developed in order to meet the requirements of the *B.C. Environmental Assessment Act*, S.B.C. 2002, c. 43. (BCEAA), and followed the methodological steps outlined in EAO's [Guideline for the Selection of Valued Components and Assessment of Potential Effects](#) (September 2013) as shown on **Figure 3-1**. This section describes each of these steps, and focuses on the process of selecting valued components (VC) and the steps followed in assessing potential Project-related residual and cumulative effects on these VCs.

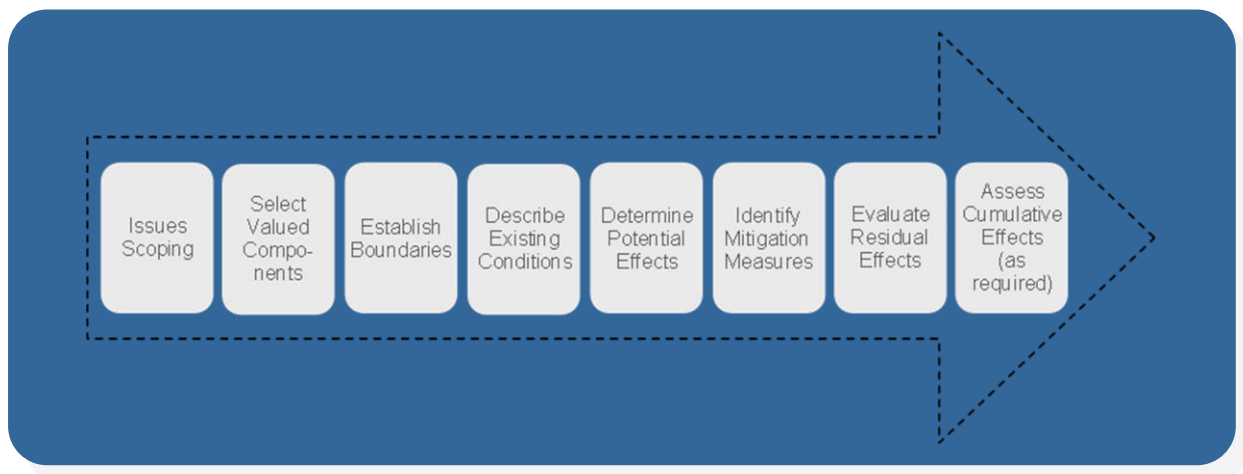

Figure 3-1 Summary of Methodological Steps

3.1 Issues Scoping and Selection of Valued Components

3.1.1 Issues Scoping

Issues scoping is the process of compiling and analyzing available information to identify environmental, economic, social, heritage, and health issues that may be related to the Project. These Project-specific issues are indicative of the local and regional values held by the public, Aboriginal Groups, and other stakeholders in the area within which the Project is proposed. They may also reflect issues of interest to the scientific community or to government agencies. The issues identified through issues scoping are used to inform the selection of VCs for the assessment (EAO 2013).

Project-related issues identified through engagement with Aboriginal Groups, public consultations, and government agency consultations are summarized in **Section 2.0 Environmental Assessment Process**.

3.1.2 Selection of Valued Components

For the purposes of an environmental assessment under the BCEAA, VCs are components of the natural and human environment that are considered by the proponent, public, Aboriginal Groups, scientists and other technical specialists, and government agencies involved in the assessment process to have scientific, ecological, economic, social, cultural, archaeological, historical, or other importance. Valued components are selected to reflect the key values of society, inform proponents on the issues to be considered as part of project design, and inform decision-makers about the costs and benefits of a project. Using VCs as the focus for the assessment concentrates efforts on matters that are central to decision-making, thereby introducing practicality and cost-effectiveness into the EA process (EAO 2013). Further detail on the VC selection process and the steps taken in selecting the VCs for Project effects assessment are presented in **Appendix A**.

The process for selecting VCs began with identifying candidate VCs based on issues identified through public, Aboriginal Group, and government agency consultation and engagement, as well as prior experience and expertise of the Project team. Candidate VCs were refined on the basis of knowledge and values gathered from Aboriginal Groups, stakeholders and public interests, scientific or regulatory interest, conservation status, and sensitivity to proposed Project effects. Candidate VCs were then evaluated against defined criteria to determine if they should be included as VCs to support the assessment of the proposed Project.

Appendix A, Table 2 lists the VCs and the rationale for selecting the final VCs, which was based on the following criteria:

- Is the component present in the relevant area?
- Does the Project have the potential to interact with and adversely affect the component?
- Is the component the ultimate receptor in a Project-related effect pathway?

Components that did not meet these criteria were not included as VCs in this assessment. For example, economic effects were not selected as a VC since the influence of the Project on economic conditions is anticipated to be positive (see **Section 1.1.7 Economic Benefits**). Similarly because the Project has limited potential for interaction with benthic and aquatic invertebrates, those components were not studied. Water and sediment quality is an example of a component that was not assessed as a VC, because it is not the ultimate receptor of potential

Project-related effects. Potential effects of the Project on water and sediment quality were assessed in terms of the effect of Project-related change in sediment and water quality on ultimate receptor VCs such as fish and fish habitat, marine mammals, vegetation, and at-risk amphibians.

The rationale for including or excluding candidate VCs for assessment is provided in **Appendix A, Table 2** and **Table 3**, respectively, with additional selection rationale in the relevant VC section. **Table 3.1-1** lists the VCs selected for assessment.

Table 3.1-1 List of Valued Components Selected for Assessment

| Pillar | Valued Component |
|----------------|---|
| Environmental | Fish and fish habitat At-risk amphibians Marine mammals Vegetation Terrestrial wildlife |
| Socio-economic | Land use Marine use Agricultural use Visual quality |
| Heritage | Heritage resources |
| Health | Human health |

3.1.2.1 Intermediate Components

In some cases, the potential effects of a project on a component are part of a longer effects pathway. In such cases, components have been classified in the assessment as intermediate components (ICs) rather than VCs.

Consideration of potential Project-related changes in ICs helps to inform understanding of potential changes that may occur along a pathway as a result of the Project and result in changes to a VC.

For example, the assessment of the human health VC depends on the results of assessing Project-related changes in air quality and atmospheric noise since each of these influences the conditions of human health. This relationship is illustrated in **Figure 3.1-1**.

Figure 3.1-1 Example of Pathway of Effects Showing the Relationship between Valued Components and Intermediate Components

The ICs in this assessment, all of which are studied in **Section 4.0 Environment Effects Assessment**, include the following:

- River hydraulics and morphology
- Surface water and sediment quality
- Underwater noise
- Air quality
- Atmospheric noise
- Traffic

Linkages between these and VCs are shown in **Table 3.1-2**, where 'x' indicates that the IC in the row informs the VC in the column.

Table 3.1-2 Linkages between Valued Components and Intermediate Components

| | | Valued Components | | | | | | | | | | |
|---|---------------------------------|-----------------------|--------------------|----------------|------------|----------------------|----------|------------|------------------|----------------|--------------------|--------------|
| | | Fish and Fish Habitat | At-risk Amphibians | Marine Mammals | Vegetation | Terrestrial Wildlife | Land Use | Marine Use | Agricultural Use | Visual Quality | Heritage Resources | Human Health |
| An 'x' indicates that the intermediate component in the row supports the assessment of the valued component in the column . | | | | | | | | | | | | |
| Intermediate Components | River Hydraulics and Morphology | x | | x | | | | x | | | | |
| | Sediment and Water Quality | x | x | x | x | | | | | | | |
| | Underwater Noise | x | | x | | | | | | | | |
| | Air Quality | | | | | | | | | | | x |
| | Atmospheric Noise | | | | | x | | | | | | x |
| | Traffic | | | | | x | x | | | | | x |

3.1.2.2 Subcomponents and Indicators

To focus the definition of VCs and provide more structure for the assessment, subcomponents are sometimes identified for VCs. For example, the marine mammal VC is focused on harbour seals and two species of sea lions which are the two marine mammals most likely to occur in the Project alignment.

Indicators are parameters that are used to measure and evaluate the interaction of the Project with a specific VC and enable a meaningful and informative assessment of Project-related effects on each VC.

Table 3.1-3 describes the subcomponents and indicators chosen for the VCs identified in **Table 3.1-2**. The rationale for their selection is included in each VC section.

Table 3.1-3 Valued Components, Subcomponents, and Indicators

| Valued Component | Subcomponents | Indicators |
|-----------------------|---|--|
| Environmental | | |
| Fish and fish habitat | <ul style="list-style-type: none"> • Salmon • Sturgeon • Eulachon • Trout • Char | <ul style="list-style-type: none"> • Likelihood of injury or mortality of fish • Total suspended solid levels and turbidity • Underwater sound levels • Loss of habitat area |
| At-risk amphibians | <ul style="list-style-type: none"> • Northern red-legged frog | <ul style="list-style-type: none"> • Presence of at-risk amphibians • Change in area of available at-risk amphibian habitat • Change in water quality in at-risk amphibian habitat |
| Marine mammals | <ul style="list-style-type: none"> • Harbour seal • California and Steller sea lions | <ul style="list-style-type: none"> • Underwater sound levels |
| Vegetation | <ul style="list-style-type: none"> • At-risk plant species | <ul style="list-style-type: none"> • Presence and extent of population(s) |
| | <ul style="list-style-type: none"> • At-risk ecosystems | <ul style="list-style-type: none"> • Presence and extent |
| Terrestrial wildlife | <ul style="list-style-type: none"> • Upland birds • Riverine birds • Small mammals | <ul style="list-style-type: none"> • Habitat loss: amount and quality of foraging and/or breeding habitat that overlaps with Project components. • Sensory disturbance: changes to usability of foraging and/or breeding habitat within the Project alignment. • Collision: risk of mortality |

| Valued Component | Subcomponents | Indicators |
|-----------------------|---|--|
| Socio-economic | | |
| Land use | <ul style="list-style-type: none"> • Land Use | <ul style="list-style-type: none"> • Consistency with land use plans and designations • Compatibility with adjacent or proximal land uses • Spatial area (ha) of change in existing land uses • Disturbance to other land uses from construction or operation activities |
| | <ul style="list-style-type: none"> • Regional Growth | <ul style="list-style-type: none"> • Change in regional population growth and distribution • Change in non-residential (industrial and commercial) development and distribution |

| | <ul style="list-style-type: none"> • Farm infrastructure and operations | <ul style="list-style-type: none"> • Change in farm operations |
| Visual quality | <ul style="list-style-type: none"> • None | <ul style="list-style-type: none"> • Change in visual quality from sensitive locations |

| Valued Component | Subcomponents | Indicators |
|--------------------|---|---|
| Heritage | | |
| Heritage resources | <ul style="list-style-type: none"> n/a | <ul style="list-style-type: none"> Disturbance of archaeological sites, objects, and features Disturbance of historical sites, objects, and features that are subject to protection under the B.C. <i>Heritage Conservation Act</i>, R.S.B.C. 1996, c. 187 (HCA) Changes in level of accessibility to archaeological sites, objects, and features Changes in level of accessibility to historical sites, objects, and features that are subject to protection under the HCA |
| Health | | |
| Human health | <ul style="list-style-type: none"> Air emissions | <ul style="list-style-type: none"> Acute inhalation risk quotient Chronic inhalation risk quotient Chronic risk quotient for multi-media exposures |
| | <ul style="list-style-type: none"> Noise and vibration | <ul style="list-style-type: none"> Annoyance associated with highway noise during operations Sleep disturbance Ability to maintain adequate speech comprehension Annoyance associated with ground-borne vibration |

3.2 Assessment Boundaries

Assessment boundaries define the scope or limits of the assessment, and encompass the areas within and times during which the Project is expected to interact with the VCs (spatial and temporal boundaries, respectively). Boundaries may also reflect constraints that may be placed on the assessment of those interactions due to jurisdictional, social, or economic realities (administrative boundaries) and limitations in predicting or measuring changes (technical boundaries) (EAO 2013).

Presence of conservation lands (including provincial Wildlife Management Areas, the National Wildlife Area, the Migratory Bird Sanctuary) and other conservation areas in the vicinity of the Project were taken into consideration when defining the assessment boundaries for specific VCs.

Spatial, temporal, administrative, and technical boundaries are identified for the VCs and the ICs.

3.2.1 Spatial Boundaries

Spatial boundaries are defined to encompass the geographic extent within which the Project is expected to have potential effects on the selected VCs.

Three assessment areas have been defined for each VC, based on the geographic scale of influence of the Project. The smallest scale includes the footprint of temporary and permanent physical works associated with the Project, and the area within which activities associated with the Project will occur. This area, referred to as the Project alignment, is common for all VCs, and is defined as follows:

- The Project footprint and all lands, including lands under water that are subject to disturbance from construction activities associated with the Project, where the Project footprint is defined as areas that are permanently altered by the Project.

The next scale of spatial boundary, referred to as the **Local Assessment Area (LAA)** comprises the area within which there is a reasonable potential for the Project or Project activities to affect the biophysical and human environment. The LAA is defined by the scope and nature of Project-related effects on specific VCs, and is defined for each VC under the corresponding effects assessment section.

A larger **Regional Assessment Area (RAA)** is used to provide context for the assessment of potential Project-related effects. The RAA is typically based on a natural transition (e.g., watershed boundary, ecological zone) or an artificial delineation (e.g., jurisdictional or economic district or zone) that is relevant to specific VCs. The RAA for each VC is defined under the corresponding effects assessment section.

The spatial boundary for the assessment of cumulative effects—i.e., effects of the interaction of residual effects of the Project on a VC with the residual effects of other projects and activities, encompasses the area within which the residual effects of the Project on a given VC are likely to interact cumulatively with the residual effects of other past, present, and reasonably foreseeable future projects and activities on that VC. In most cases, the RAA can be used as the spatial boundary for the assessment of potential cumulative effects. Spatial boundaries of the cumulative effects assessment area are defined under the discussion on potential cumulative effects on specific VCs.

An approach similar to the one outlined above, based on the nature, scope and extent of potential Project-related effects, was used to define spatial boundaries of the study areas for ICs.

3.2.2 Temporal Boundaries

The temporal boundaries defined for the assessment encompass the periods during which the Project is expected to interact with the VCs and ICs. Temporal characteristics (timing) of the Project construction phase (including decommissioning of temporary construction-related facilities and the Tunnel), and operation phases are defined in **Section 1.1.3 Project Phases and Schedule**. The temporal boundaries established for the assessment of adverse Project effects on the VCs and ICs include these Project phases.

3.2.3 Administrative and Technical Boundaries

The administrative boundaries for the Project refer to limitations imposed on the assessment by jurisdictional or economic constraints. Examples are municipal boundaries and wildlife management zones. Technical boundaries might include limitations in information, data analyses, and data interpretation relevant to particular VCs and ICs (e.g., unavoidable data gaps or model limitations). Administrative or technical boundaries may not be applicable to all VCs and ICs.

3.3 Existing Conditions

A description of existing conditions of each VC and components that support it, based on requirements set out in the AIR, is provided in the corresponding effects assessment section, along with trends where relevant. The data for existing conditions were collected through a combination of desk studies and field programs, with the latter being used to fill gaps in knowledge about existing conditions.

Information contained in this section for each VC and IC, includes:

- A description of the existing (or baseline) conditions within the assessment area with sufficient detail to allow for the identification, understanding, and assessment of potential Project-VC/IC interactions.
- A description of the quality and reliability of the existing (or baseline) data and its applicability for the purpose used, including any gaps, insufficiencies and uncertainties, particularly for the purpose of monitoring activities.

- Reference to natural and/or human-caused trends that may alter the environmental, economic, social, heritage and health setting, irrespective of the changes that may occur as a result of the Project or other project and/or activities in the area.
- Explanation of if and how other past and present projects and activities in the assessment area have affected or are affecting the VC.
- Documentation of the methods and data sources used to compile information on existing (or baseline) conditions, including any standards or guidelines followed. Where additional Project and VC-specific field studies were conducted, the scope and methods to be used have followed published documents pertaining to data collection and analysis methods. Where methods used for the assessment deviate from applicable published guidance, the rationale for the variance is provided.
- A description of the Traditional Ecological Knowledge (TEK), including Aboriginal Traditional Knowledge (TK), that is used in the VC assessment.

The methods used to collect and assemble data on existing conditions are based on the following procedures and standards:

- Collection, analysis, and presentation of data follow the appropriate provincial or federal standards (e.g., B.C. Resource Information Standards Committee)
- Information from Aboriginal Groups traditional knowledge/traditional use (TK/TU) studies is incorporated alongside information from scientific studies, where relevant and appropriate
- Maps are used to show data collection points
- Existing reports and documents are appended or referenced, as appropriate

The sections that describe the assessment methods for each VC and IC also provide the following:

- The rationale for selecting sampling sites and analytical parameters, where applicable.
- Descriptions of field and laboratory methods, as well as quality assurance and quality control measures applied.
- Comments regarding the quality and reliability of these data and their applicability for the purpose used, with the identification of gaps, insufficiencies and uncertainties.

Where appropriate, technical volumes describing baseline studies and existing conditions are included as appendices, with key findings contained in these technical volumes summarized in the Application.

3.4 Potential Effects

The assessment of potential effects of the Project on each VC begins with a description of Project activities and physical works that could result in an environmental effect. A description of Project-related activities is provided in **Section 1.1.4 Project Components and Activities**.

A matrix, presented in **Appendix B, Table 1**, which shows potential interactions between Project activities and each VC and IC during specific Project phases, was used to identify potential effects on VCs/ICs. Determination of the potential for an activity to interact with each VC and IC is based on review of relevant literature, other environmental assessments, and professional judgment. Feedback from Aboriginal Groups, the public, stakeholders and government agencies on VC/IC selection and assessment was incorporated, as relevant.

Where it was determined that an interaction between a Project activity and VC or IC could occur, a preliminary effects-rating using the categories defined in **Table 3.4-1** was assigned.

Table 3.4-1 Preliminary Effects-Rating for Project Interactions

| Rating | Description |
|------------------|---|
| No effect | An interaction with the Project activity is likely to occur but would not be expected to result in a detectable or measurable effect on the VC. |
| Potential effect | An interaction with the Project activity is likely to occur and would be expected to result in a potential effect on the VC. |

For each activity that is anticipated to interact with a VC, a rationale that supports the preliminary effects rating is provided, along with a description of the nature of the interaction and anticipated effect(s). Interactions with potential effects are carried forward in the assessment. The methods and criteria used to justify any excluded project activity-VC interaction will be provided.

In cases where a VC could potentially be affected indirectly by a Project-related change in another component (i.e., an IC as described in **Section 3.1.2.1 Intermediate Components**), interactions between Project activities and the ICs, and associated changes in the ICs were identified using a process similar to the one described above for VCs. Project-related changes in ICs are assessed in terms of the effects of those changes on the VCs that are the ultimate receptors of the effects of the Project.

3.5 Mitigation Measures

Where potential effects are determined to occur, mitigation measures are identified to avoid or reduce potential adverse effects of the Project on VCs and subcomponents. Mitigation measures that will reduce or eliminate an adverse effect are described for each VC and IC, with an emphasis on how these measures will help alter the effect. Mitigation measures for VCs and ICs include the following information, where relevant:

- A description of the approach to identify and analyze mitigation measures, including any management and compensation plans proposed, which will be implemented to address potential effects.
- A description of the mitigation measures incorporated into the Project, including site and route selection, project scheduling, project design, and construction and operation procedures and practices.
- A description of any standard mitigation assumed or proposed to be implemented, including consideration of best management practices, environmental management plans, environmental protection plans, contingency plans, emergency response plans, and other general practices.
- An indication of how the mitigation measures will mitigate the potential adverse effects on the VC or IC.
- The rationale for the proposed mitigation measures, including why further avoidance or reduction measures for adverse effects may not be considered feasible, and the need for and scope of any proposed compensation or offset.
- An evaluation of the anticipated success of each mitigation measure and a description of the rationale and analysis for these evaluations, including, where relevant, a description of the potential risks and uncertainties associated with use of the mitigation.
- A description of the time required for mitigation to become effective.

A summary of the mitigation measures by Project phase is included, as well identification of mitigation measures that are in management or compensation plans. In some cases, mitigation may include monitoring programs to verify results of the assessment, or monitor effectiveness of mitigation measures. If appropriate, or applicable, mitigation strategies discussed on the Applications will include mitigation measures or opportunities for enhancement of the environment in addition to avoiding or minimizing Project-related effects.

3.6 Characterization of Residual Effects

Where residual effects are expected to persist after implementation of mitigation measures, such effects are characterized for each VC/IC using the criteria listed below. Some criteria definitions have been developed for specific VCs or ICs, and these are described in each effects assessment section. The assessment of effects also considers the likelihood of each predicted residual effect occurring.

The following generalized definitions are used as a guide for establishing specific effects characteristics for each VC/IC.

- **Direction** refers to the overall nature of the residual effect. The direction of Project effects may be positive (i.e., beneficial), neutral, or negative (i.e., adverse).
- **Magnitude** refers to the amount of change to the existing condition of a VC/IC. Magnitude is generally measured in terms of the proportion of the VC/IC that is affected within the assessment area (LAA or RAA) relative to the range of natural variation (or historic variation, in the case of human environment VCs). The definition of magnitude is VC/IC-specific.
- **Geographic extent** refers to the area over which Project-related changes would occur. The geographic extent of effects may be site-specific (limited to the Project alignment), local (limited to the LAA), regional (limited to the RAA), or beyond. The definition may vary by VC/IC.
- **Duration** refers to the period of time for a VC/IC to return to its existing condition. The duration of an effect may be short-term, long-term, or permanent (i.e., the VC/IC won't return to its existing condition). Definitions of short- and long-term vary by VC/IC, to take into account VC/IC-specific temporal characteristics, such as breeding times in the case of wildlife.
- **Frequency** refers to the number of times that an effect might occur. The frequency of an effect may be continuous, frequent, uncommon, or rare.
- **Reversibility** refers to the degree to which existing conditions can be regained after the factors causing the effect are removed. Effects can be reversible, irreversible (permanent), or partially reversible.

Residual effects are discussed in the context of the current and future sensitivity of the VC/IC and its resilience to change caused by the Project. Consideration of context is based on the description of existing conditions of the VC/IC, which reflect cumulative effects of other projects and activities that have been carried out, and especially information about the impact of natural and human-caused trends in the condition of the VC/IC. Sensitivity or resilience is ranked using qualitative terms such as low, medium, or high, where appropriate.

The characterization of each residual effect and the rationale used to support each rating are summarized in the relevant effects assessment section of each VC/IC.

For each VC/IC, a table is provided describing the residual effects using the residual effects criteria context, magnitude, extent, duration, reversibility, and frequency, as defined in EAO's Guideline for the Selection of Valued Components and Assessment of Potential Effects. Where feasible, these criteria will be described quantitatively. When residual effects cannot be characterized quantitatively, the effects have been characterized qualitatively. The use of any qualitative terms (e.g. high, moderate, low, etc.) is accompanied by distinct definitions for each of these rankings. An explanation is included for the conclusion reached for each criterion used to characterize a residual effect.

3.7 Likelihood

The likelihood for all residual adverse effects occurring is assessed using appropriate quantitative or qualitative terms, in sufficient detail to help understand how the conclusions are reached. Definitions of any qualitative terms, such as 'low', 'moderate', or 'high' probability for each VC/IC are provided.

3.8 Proponent's Determination of Significance

For each VC, a conclusion of significance of residual adverse effects is provided. To determine the significance of a residual effect, the effects assessment methods consider the nature and likelihood of each residual effect, and the context within which it is expected to occur. Significance thresholds are defined for each VC based on federal and provincial regulatory requirements, standards, objectives, or guidelines, as well as resource management objectives, community standards, scientific literature, or ecological functions, as applicable. Residual effects on ICs along the pathway of effects are reflected in the significance determination of each receptor VC.

3.9 Confidence and Risk

The level of confidence (low, moderate, or high) for each residual effect prediction, associated with both the significance and likelihood, is provided. The level of confidence is based largely on professional judgment, and takes into consideration factors such as uncertainties, quality of available data, as well as nature and extent of potential effect. A description of any measures to reduce uncertainty through monitoring, adaptive management, or other follow-up programs, is provided.

A risk assessment for the residual effects prediction will be conducted when the following conditions apply:

- There is a high degree of uncertainty in an effects prediction (i.e., low confidence)
- There is a possibility of a significant adverse effect
- Follow-up programs may not be sufficient to manage the potential risk

If additional risk assessment is required, the process and methodology used for this analysis and the conclusions are provided, including the range of likely, plausible and possible outcomes with respect to likelihood and significance.

For each VC/IC, a summary is provided of the Project interactions, proposed mitigation measures, and the characterization of residual effects.

3.10 Cumulative Effects Assessment

A cumulative effects assessment is conducted when adverse residual effects of the Project on a VC/IC have the potential to interact with the residual effects of other certain and reasonably foreseeable projects and activities.

The methods for cumulative effects assessment are based on federal guidance provided in the *Cumulative Effects Assessment Practitioners Guide* (Hegmann et al. 1999). As identified in [EAO's Guideline for the Selection of Valued Components and Assessment of Potential Effects](#), the steps outlined in **Figure 3.10-1** below are used to determine residual Project effects and the subsequent cumulative effects assessment.

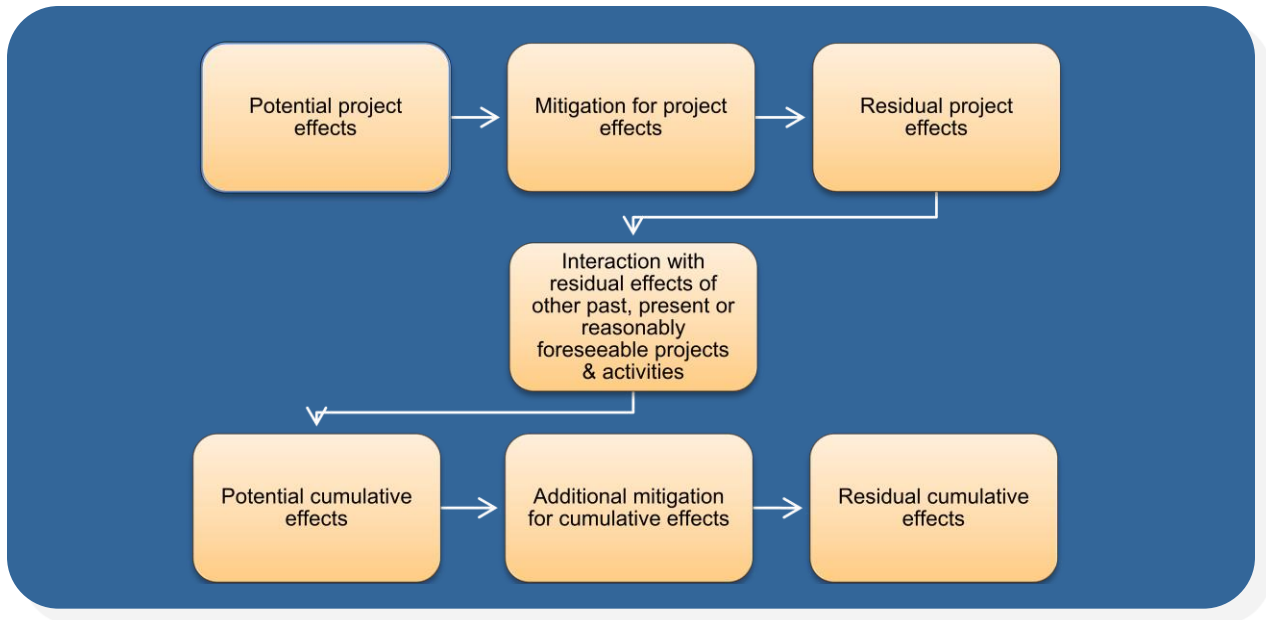

Figure 3.10-1 Steps to Determine Residual Project and Cumulative Effects

Unless stated otherwise, the effects of past developments are considered to be included in the existing conditions of a VC or IC. The cumulative effects assessment also considers approved land use plan provisions and overlapping effects associated with others present (i.e., construction is underway during development of the Application), and future certain or reasonably foreseeable developments. A list and details of other present and future certain or reasonably foreseeable developments that are included in this assessment is provided in **Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**.

Potential residual effects of the Project that are negligible (not detectable or measurable) are not carried forward in the cumulative effects assessment. Whenever a residual effect of the Project has been excluded from detailed consideration in the cumulative effects assessment, the rationale for this exclusion is provided in the corresponding VC/IC assessment section.

3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities

The developments listed below have been identified as candidates for inclusion in the assessment of cumulative environmental effects of the Project, based on a review of the following: the EAO Project Information Centre (e-PIC), the Canadian Environmental Assessment Registry, and project websites. Locations of these developments are shown on **Figure 3.10-2**.

The following selection criteria were used in identifying projects and activities to be considered in the assessment of cumulative effects:

1. The project or activity could result in a residual effect or change on a VC or IC.
2. The Project-specific residual effect or change on a VC or IC is likely to act in a cumulative fashion with the residual effects of other present, and certain and reasonably foreseeable future projects and activities in the area.

Influence of projects and activities that have already been built/conducted, including but not limited to Deltaport, BC Ferries Terminal at Tsawwassen, Vancouver International Airport, Boundary Bay Airport, Fraser Wharves, Coast 200 Terminals, Lehigh Hanson Cement Plant, Varsteel, Seaspan Ferries Corporation Tilbury Terminal, and FortisBC Tilbury LNG Plant (existing), will be included in the assessment of baseline conditions of each VC; these projects have therefore not been included in the list of current projects and activities to be included in the cumulative effects assessment.

3.10.1.1 Certain Developments and Activities

Tilbury Liquefied Natural Gas (LNG) Facility Expansion Project: FortisBC is currently expanding the Tilbury Island LNG storage facility in Delta to provide increased LNG supply in the transportation sector, remote communities, industry, and the marketplace. The project will add approximately 46,000 cubic metres of LNG storage. Upgrades to existing and construction of new infrastructure are land-based. Construction commenced in the third quarter of 2014; the project is expected to be operational by November 2016. The project is situated approximately four kilometres upstream of the Project alignment.

Vancouver Airport Fuel Delivery Project: Having received an Environmental Assessment Certificate in December 2013, construction for this project is anticipated to be completed by Spring 2018. The project includes upgrades to an existing marine terminal in the lower Fraser River, and construction of a new aviation fuel receiving facility approximately 2.5 kilometres upstream of the Project alignment, as well as construction of a new pipeline to transfer aviation fuel to Vancouver International Airport through Richmond. During project operation, periodic (i.e., once every two years) maintenance dredging, which will not spatially overlap with the Project, will occur between the marine terminal and the Fraser River South Arm navigational channel to maintain adequate under-keel clearance for vessels calling at the terminal. Marine terminal upgrades are scheduled to occur in 2016. The project is anticipated to be operational by spring 2018.

Maintenance Dredging of the Lower Fraser River: Port of Vancouver carries out annual maintenance dredging of the lower Fraser River to maintain adequate depth in the navigational channel for commercial vessels to safely access port facilities.

Port of Vancouver Habitat Enhancement Program: The Habitat Enhancement Program is a Port of Vancouver initiative focused on creating, restoring and enhancing fish and wildlife habitat. The program consists of projects around the Lower Mainland and is intended to provide a balance between a healthy environment and future development projects that may be required for port operations. The Sturgeon Banks project is being considered as a potential habitat restoration site for the Habitat Enhancement Program. This project is located approximately ten kilometres from the Project.

3.10.1.2 Reasonably Foreseeable Developments

Fraser Surrey Docks Direct Transfer Coal Facility (Texada Coal): Recently approved by Port of Vancouver, this project involves development of a direct transfer coal facility, including supporting rail and yard infrastructure, to handle up to four million metric tonnes of coal per year. The project includes transfer of coal from rail onto barges, and barge transport of coal from the terminal to Texada Island. Marine vessel traffic is expected to include 500 cargo barges and 80 bulkers per year. The project is expected to be in operation at the time Project construction is proposed to commence. The proposed coal transfer facility location is approximately upstream 15 kilometres from the Project alignment.

WesPac Tilbury Marine Jetty Project: This proposed project includes construction of a marine jetty adjacent to the existing FortisBC Tilbury LNG Facility (discussed under Certain Developments above). Located in the lower Fraser River at Tilbury Island, in Delta, this jetty is intended for the berthing and transferring of approximately four billion cubic metres of LNG per year to marine barges and carriers for delivery to local fuel and offshore export markets. Proposed project construction activities include the removal of existing abandoned marine infrastructure, and construction of a new marine jetty (i.e., access trestle, loading platform, and mooring dolphins), and land-based infrastructure to receive processed LNG for transfer to marine vessels. Supply of LNG for the project is proposed to come via a pipeline from the existing adjacent FortisBC Tilbury LNG storage facility. The project is currently under review by the National Energy Board, and is subject to environmental assessments by the Canadian Environmental Assessment Agency (CEA Agency) and the EAO. In July, 2015 the CEA Agency approved the substitution of the federal environmental assessment process by that of the BCEAA for this Project. Construction is anticipated to begin in late 2016 and be operational in early 2018. The project is situated approximately four kilometres upstream of the Project alignment.

Fortis BC Tilbury LNG Facility Expansion Project – future phase: The proposed facility expansion will include an additional (second) storage tank. The second storage tank will approximately double the storage capacity up to one billion standard cubic feet. Current project plans outline an in-service date of 2016 for the proposed facility. The Tilbury LNG project is located approximately four kilometres from the Project.

Roberts Bank Terminal 2: This proposed project comprises a new three-berth marine container terminal at Roberts Bank in Delta to facilitate an additional 2.4 million twenty-foot equivalent units of container capacity per year. This project is currently under review, and will undergo an environmental assessment by a review panel. Project construction is proposed to begin in 2018 and proceed for a five-and-a-half year period. The proposed location of the marine terminal is approximately 13 kilometres from the Project alignment.

Ladner Harbour Revitalization: The Corporation of Delta is proposing to redevelop and revitalize the waterfront at Ladner Harbour. The proposed redevelopment will include new waterfront buildings and infrastructure. Conceptual pre-design drawings do not specify in-river construction activities. The project is at its conceptual pre-design phase and a schedule for project construction has not been identified yet. Delta has issued development variance permits for several lots. The project is approximately four kilometres downstream of the Project alignment.

South Richmond Terminal Project: Lehigh Hanson is proposing to develop an aggregate (sand and gravel) processing and distribution facility on leased property in southeast Richmond, at the south end of No. 7 Road. Proposed project construction includes establishment of an aggregate wash plant, material stockpiles, reclaimer, truck loading and rail loading facilities, and two marine barge berths in the lower Fraser River. The project is approximately 3.5 kilometres downstream of the Project alignment. The project is currently under review. Construction is proposed to begin between 2017 and 2018, and the site is proposed to be operational in 2020.

Pattullo Bridge Replacement: TransLink is proposing a new, four lane Pattullo Bridge, to be designed to accommodate a potential future expansion to six lanes. The proposed replacement bridge would have modern lane widths, better connections, a centre barrier and high-quality cycling and pedestrian facilities. The project is located approximately 16 kilometres from the Project with completion tentatively planned for 2022.

Kinder Morgan Trans Mountain Pipeline Expansion Project: Trans Mountain is proposing an expansion of this existing 1,150-kilometre pipeline between Strathcona County (near Edmonton), Alberta and Burnaby, BC. The proposed expansion would create a twinned pipeline that would increase the nominal capacity of the system from 300,000 barrels per day to 890,000 barrels per day. The Facilities Application was filed in December 2013. It is currently before the National Energy Board and the hearing process is underway. The Project entered the BC environmental assessment process on April 8th, 2016. The Burnaby Terminal is the terminus of the project's mainline, storing and distributing both crude oil and refined products through separate pipelines to local terminals, a refinery, and the Westridge Marine Terminal. The Burnaby Terminal is located on the south side of Burnaby Mountain, approximately 20 kilometres northeast of the Project. The Westridge Marine Terminal is located on the south shore of Burrard Inlet, approximately 21 kilometres northeast of the Project.

Relocation of BC Hydro's transmission line that runs through the George Massey Tunnel: A BC Hydro transmission line runs through the George Massey Tunnel and will require relocation. Conceptual designs for three alternatives for relocation are being studied. According to BC Hydro, the leading alternative at this time is an overhead transmission line crossing the Fraser River. Public consultation was carried out in November 2015 on all three alternatives.

3.10.2 Conducting a Cumulative Effects Assessment

A rationale that supports the selection of spatial boundaries for the assessment of cumulative effects on each VC/IC is provided in the corresponding effects assessment section, including maps. The cumulative effects assessment is conducted for both construction and operation-related residual effects.

After the assessment area boundaries are determined, the list of present, and certain and reasonably foreseeable future developments is reviewed to determine if their incremental residual effects have potential to overlap spatially and temporally, and interact in a cumulative manner with the adverse residual effects of the Project. A table of all past, present and reasonably foreseeable developments that interact is provided for each VC/IC, where required. Where an interaction is considered likely, the potential cumulative effects are rated using the same categories described in **Section 3.4 Potential Effects** (i.e., no effect, potential effect). Potential interactions that have a rating of no cumulative effect are not carried forward for further analysis. The assessment considers technically and economically feasible measures to avoid, reduce, or otherwise mitigate potentially adverse cumulative effects or changes, including a description of how these measures might modify the characteristics of an effect or change. Residual cumulative effects that may persist following the application of mitigation are characterized using the same definitions detailed in **3.6 Characterization of Residual Effects**.

Where relevant, the significance of cumulative effects is determined by comparing the predicted future condition of a VC, taking into consideration the predicted cumulative effects with the threshold of significance defined for the VC. A level of confidence associated with the likelihood and significance determinations of each residual cumulative effect prediction is provided.

An approach similar to the one outlined above was used to identify potential and assess cumulative changes in ICs where there was a potential for Project-related changes in the component to act incrementally with changes associated with other projects and activities. Any cumulative effect that is identified for an IC is considered in the cumulative effects assessment of the corresponding receptor VC(s).

3.11 Follow-up Strategy

Where a residual adverse effect or cumulative effect is identified for a specific VC or IC, the Application will include a description of a follow-up strategy, where appropriate, that:

- Identifies the measures to evaluate the accuracy of the original effects prediction.
- Identifies the measures to evaluate the effectiveness of proposed mitigation measures.
- Proposes an appropriate strategy to apply in the event that original predictions of effects and mitigation effectiveness are not as expected. This may include reference to further mitigation, involvement of key stakeholders, Aboriginal Groups, government agencies and any other measures deemed necessary to manage the issue.

APPENDIX A

Summary of Issues Identification and Valued Component Selection

1.0 Valued Component Selection Method and Results

This section describes the process for selecting the valued components (VCs) that will be studied, reported on, and assessed as part of the environmental assessment process. VCs describe components of the natural and human environment that are of particular importance of value to the proponent, public, Aboriginal Groups, scientists, other technical specialists, and government agencies. Proper selection of VCs is an important step in developing an environmental assessment that is thorough and adequate. VCs provide focus to the assessment and facilitate identification and evaluation of potential Project-related interactions in Part B of the Application. The method described here is consistent with advice provided in *Guideline for the Selection of Valued Components and Assessment of Potential Effects* (BC EAO 2013).

1.1 Key Terms

This section presents the key terms associated with the VC selection methods.

Pillars: The BCEAA requires an EA process to consider the environmental, economic, social, heritage, and health effects of a reviewable project. EAO refers to these five effects categories as pillars. The *Guideline for the Selection of Valued Components and Assessment of Potential Effects* (EAO 2013) specifies linkage to at least one of the five pillars as an attribute of a VC.

Issues: Issues are the broad range of environmental, economic, social, heritage, and health interests of government, Aboriginal Groups, the public, and the scientific community with respect to the Project. Issue identification is the first step in the VC selection process, and involves developing a list of issues related to each pillar that could be associated with construction and operation of the Project. Issue identification is undertaken through research, literature review, and engagement and consultation with interested parties.

Valued Components: According to guidance provide by the EAO, VCs are defined as “components of the natural and human environment that are considered by the proponent, public, Aboriginal Groups, technical specialists, and government agencies involved in the assessment process to have scientific, ecological, social, cultural, archaeological, historical, or other importance” (EAO 2013). VCs are selected to reflect the key values of society and inform proponents on the issues that need consideration as part of project design, and to inform decision-makers about the costs and benefits of a project. Selection of VC focuses the EA process on matters that need to be taken into account in making decisions; introducing practicality and cost-effectiveness into the EA process. The EAO’s VC selection guidance identifies the following essential VC attributes:

- Relevant to at least one of the five pillars and clearly linked to issues raised in relation to the Project.

- Comprehensive, enabling a full understanding of important project-related potential effects.
- Representative of societal values and important features of the environment.
- Responsive to the potential effects of the project.
- Concise, to facilitate clear understanding and minimize redundancy.

Indicators: Indicators are the parameters used to measure and evaluate the interaction of the Project with a specific VC. Indicators should be relevant, practical, measurable, responsive, accurate, and predictable (EAO 2013). VCs selected for assessment in the EA process are associated with measurable indicators to enable a meaningful and informative assessment of project-related effects on each VC.

Candidate Valued Components: Candidate VCs represent a subset of the issues identified during information gathering that have been evaluated against pre-set criteria. Candidate VCs are identified from the list of issues and must have the potential to interact with the proposed Project and experience potential adverse Project-related effects. They also reflect the values and priorities of government, Aboriginal Groups, the public, and the scientific community.

Intermediate Components: Intermediate components are environmental components along the pathway of an effect that are used to support the assessment of a VC. For example, water quality is an intermediate component when information from its study is used to support the assessment of the fish and fish habitat VC.

1.2 VC Selection Method

Building on guidance provided by the EAO (BC EAO 2013), the method for selecting VCs for the Project has followed a process that involves the following three steps:

1. Information gathering and identification of potential issues.
2. Issues scoping and identification of candidate VCs.
3. Evaluation of candidate VCs and selection of final VCs.

This section describes the key steps followed to determine the selection of Project-related VCs (**Figure 1**).

1.2.1 Step One – Information Gathering and Issues Scoping

Information was collected from a number of sources to support issues identification and scoping. Publicly-available information was reviewed by technical experts with knowledge of the components included in the five pillars (i.e., environmental, health, heritage, social and economic). This review supported the development of a list of Project-related issues that reflects the interests of government, Aboriginal Groups, the public, and the scientific communities. The Ministry conducted public consultation and Aboriginal Groups engagement on various options for the development of the Project, and results of this and information from environmental assessments of similar and related development projects in the Lower Mainland informed issues identification.

1.2.2 Step Two – Identification of Candidate Valued Components

Building on the list of issues identified during Step One, technical experts linked the issues to an environmental, economic, health, social or heritage component. Then these experts, with a thorough knowledge of the Project alignment, screened each component using a two-part test to determine whether it should be a candidate VC. The first test for inclusion as a candidate VC required a positive answer to two questions:

- Is the component present in the study area?
- Does the Project have the potential to interact with and adversely affect the component?

If the answer was “yes” to the first test questions, the component was further evaluated using a second test with a discipline-specific focus. Any positive answer to one of the questions in the second test was considered confirmation that the component was a candidate VC. The second test questions evaluated by discipline-specific technical experts were:

- Is the component important to government agencies?
- Is the component important to Aboriginal Groups?
- Is the component important to conservation or science?
- Is the component important to other stakeholders?

Discipline-specific criteria may have been developed to determine importance for each of these questions, or such criteria may have used published thresholds; e.g., federal or provincial designation as threatened species was the criteria for determining importance to conservation or science for the ecological components.

1.2.3 Step Three – Evaluation of Candidate Valued Components

In Step Three, candidate VCs were evaluated to minimize redundancy and duplication, and to focus the assessment on Project-environment interactions that are measurable and informative. In addition, indicators that will be used as the metrics for measuring and reporting on the condition and trend of the candidate VCs were selected.

In this step each candidate VC was screened against a range of practical considerations to determine if the candidate VCs were suitable for inclusion in the VC list. These considerations were:

1. Can effects on the candidate VC be effectively measured and monitored; i.e., are there suitable indicators? Each candidate VC must have at least one indicator which can be used to measure and report on potential effects.
2. Is the issue better represented by another VC, i.e., is there duplication in effects assessment? Where appropriate, candidate VCs were grouped and combined under the umbrella of a more general VC. For example, salmon, sturgeon, eulachon, trout, and char have been grouped under a fish and fish habitat VC. Each species is considered a sub-component of the umbrella VC, fish and fish habitat.
3. Where does the candidate VC fit in the effects pathway? In some cases, the potential effects of a project on the candidate VC are part of a longer-effects pathway. These candidate VCs are classified as intermediate components rather than a VC. For example, air quality and atmospheric noise are intermediate components along the pathway of effects leading to the ultimate receptor, human health.
4. Is the candidate VC protected through a legal instrument? This screening step eliminates components for which a non-EA process regulatory framework exists that includes legally binding requirements to ensure protection of the component (e.g., worker safety is managed under the BC *Occupational Health and Safety Regulation* and therefore does not need to be considered as a VC).

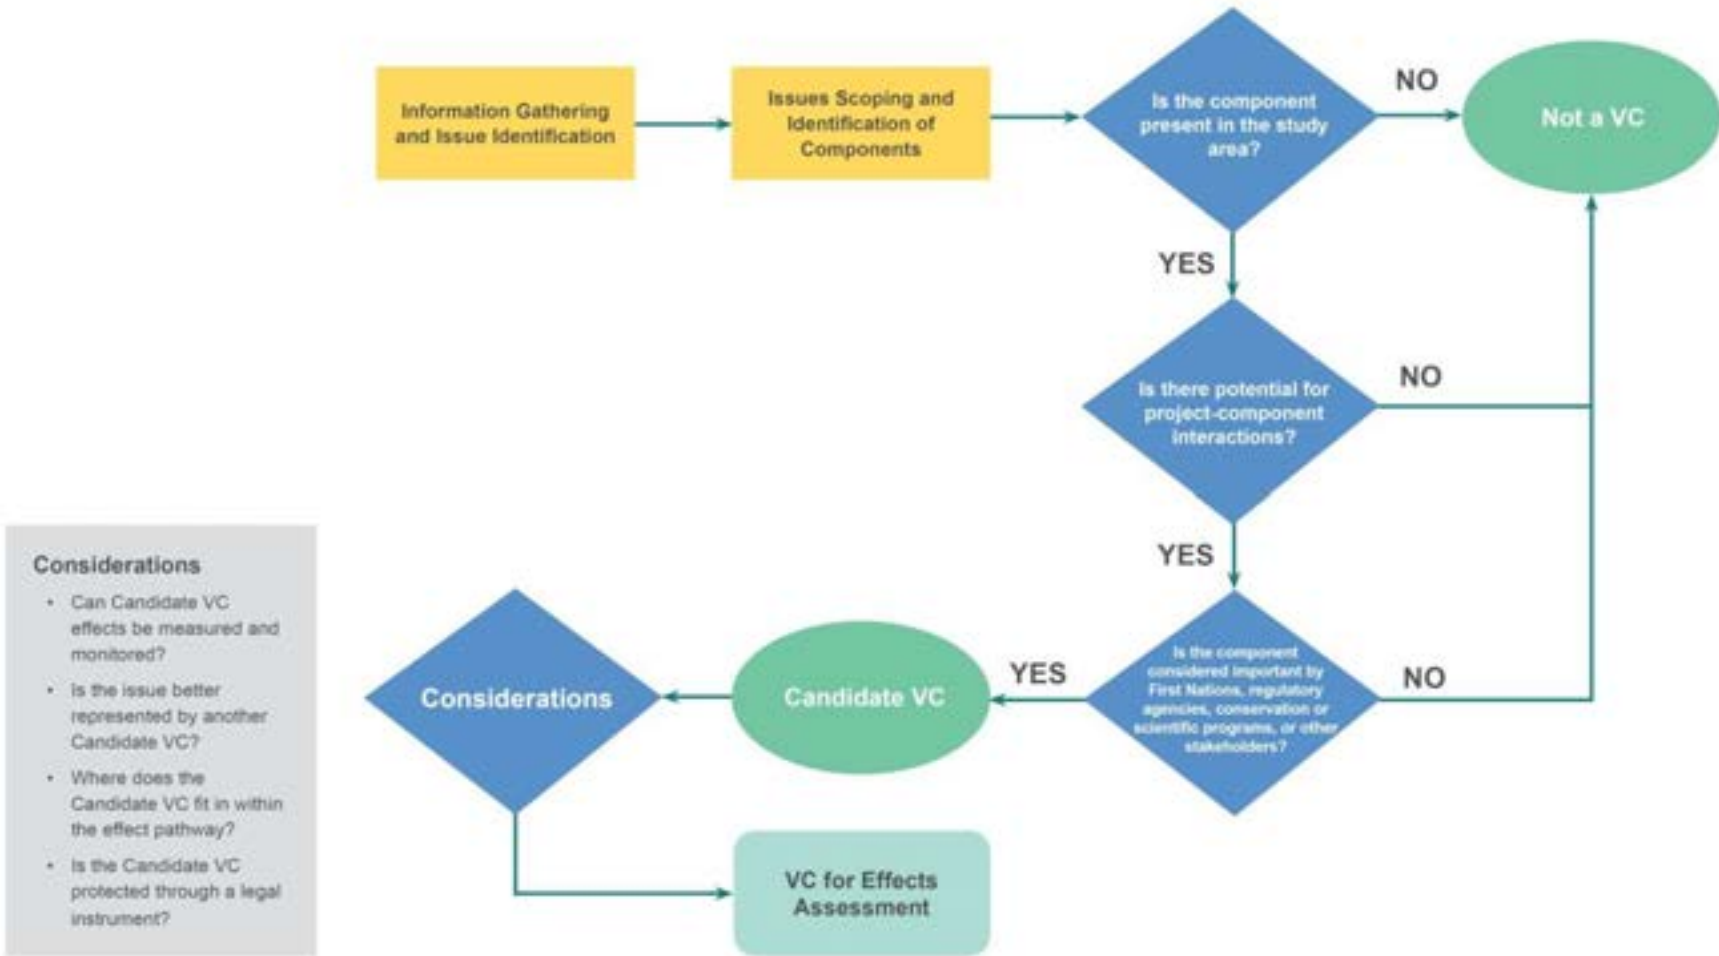

Figure 1 VC Selection Process

1.3 VC Selection Results

Potential Project-related issues were identified based on feedback received from initial public, Aboriginal Group, and agency consultation, knowledge of technical experts on the Project team, and review of relevant documents, including environmental assessment documentation on other recent projects in the area. These issues were linked to candidate VCs, grouped under the five assessment pillars, and the potential for Project components and activities to interact with the candidate VCs was assessed. An overview of the results of this assessment is provided in **Table 1**.

A decision on the need for including each candidate VC in the assessment, and whether it will be assessed as a VC (i.e. the ultimate receptor of Project-related effects) or an intermediate component (i.e. a component along the pathway of effects of the Project) was made based on the potential for interaction with Project components and activities, and anticipated nature of such interaction.

An overview of the VCs and intermediate components selected for assessment, issues related to them, and the rationale for their selection is provided in **Table 2**. Candidate VCs or sub-components of candidate VCs that were excluded from assessment, and the rationale for their exclusion are presented in **Table 3**.

| <p>Heritage Resources</p> <ul style="list-style-type: none"> • Physical disturbance to heritage sites, objects, and features • Accessibility to heritage sites, objects, and features <ul style="list-style-type: none"> ▫ opportunities for scientific research, preservation, or public appreciation ▫ exposure to vandalism and unauthorized collection | <p>Protection of archaeological and heritage resources, including intangible heritage sites, has been identified as of specific importance by Aboriginal Groups.</p> | <p>BCEAA requires consideration of adverse environmental effects.</p> <p>The B.C. <i>Heritage Conservation Act</i> protects heritage resources.</p> | <p>The Project alignment may contain unknown heritage resources that could be affected by construction activities.</p> | <p>The Project alignment could contain heritage resources that are important to the public.</p> | <p>Heritage resources was selected as a valued component due to its importance to Aboriginal Groups, the public, other stakeholders, and due to its regulatory importance.</p> |

Table 3 Rationale for Exclusion of Candidate Valued Components, Intermediate Components, or Subcomponents

| Candidate Valued Component, Intermediate Component, or Subcomponent | Rationale for Exclusion |
|--|---|
| Soil and groundwater quality (Candidate VC) | <ul style="list-style-type: none"> • The Project has the potential to interact with potentially contaminated soil and groundwater; however, potential issues related with any such interaction will be managed according to the requirements of the <i>Environmental Protection Act</i>, and associated regulations. |
| Species listed under the Species At Risk Act (SARA) (Candidate VC) | <ul style="list-style-type: none"> • Individual species at risk are better represented as subcomponents under the following VCs: <ul style="list-style-type: none"> ▫ Fish and Fish Habitat ▫ Marine Mammals ▫ At-risk Amphibians ▫ Vegetation ▫ Terrestrial Wildlife |
| Wetlands (Candidate VC) | <ul style="list-style-type: none"> • Potential effects on wetlands (including estuaries) can be effectively considered within the assessment of the following VCs: <ul style="list-style-type: none"> ▫ Vegetation ▫ Terrestrial Wildlife • Assessment of potential Project-related effects on wetlands in terms of influence on vegetation and wildlife will be supported by the following studies: <ul style="list-style-type: none"> ▫ River Hydraulics and River Morphology ▫ Sediment Quality and Water Quality |
| Southern resident killer whale (SRKW) (Candidate Marine Mammal VC subcomponent) | <ul style="list-style-type: none"> • SRKW are not present in the Fraser River and therefore no direct interaction with Project activities is expected. • Preliminary results of underwater noise modelling indicate underwater noise generated during construction will not travel beyond the Fraser River. • Preliminary results of fish and fish habitat studies suggest potential effects on availability of Chinook salmon as food source for South Resident Killer Whale are negligible. |
| Benthic and aquatic invertebrates (Candidate intermediate component) | <ul style="list-style-type: none"> • Benthic and aquatic invertebrates are present within the Project alignment. • The Project alignment within the Fraser River South Arm is known to be a dynamic environment lacking the characteristics which are expected to promote highly productive benthic and aquatic invertebrate populations. • The Project has limited potential for interaction with benthic and aquatic invertebrates and their habitat. • Any notable interactions (e.g., Tunnel decommissioning) will occur over a very limited timeframe, and no long-term adverse effects are anticipated. |
| Nocturnal owls (except barn owls) (Candidate Terrestrial Wildlife VC subcomponent) | <ul style="list-style-type: none"> • There is limited potential for interaction with the nocturnal owls (except barn owls) and the Project. There are few affected forest areas with potential for owl species, and where they do occur, protection afforded to such species under the <i>Wildlife Act</i> and standard best management practices assures the identification and protection of active nests prior to felling. |
| At-risk terrestrial invertebrates (Candidate Terrestrial Wildlife VC subcomponent) | <ul style="list-style-type: none"> • Habitat in the Project alignment is unsuitable for the at-risk terrestrial mollusk species, butterfly species, and dragonfly species that occur in the Lower Mainland as there are no host plants present. • There is no potential for interaction between at-risk terrestrial invertebrates and the Project. |
| Sandhill cranes (Candidate Terrestrial Wildlife VC subcomponent) | <ul style="list-style-type: none"> • There is confirmed sandhill crane foraging during fall in the vicinity of the Project alignment, but there will be no footprint effects on this foraging habitat due to the Project. • There is limited potential for interaction between sandhill cranes with the Project. • Visual and aural effects on sandhill crane will be largely unchanged from the current situation. • The effects of the nearby South Fraser Perimeter Road on sandhill crane are being monitored and the preliminary conclusions of their patterns of use in southwest Delta can be used as a basis for not including sandhill cranes as a subcomponent for the Terrestrial Wildlife VC. • Addressed to some extent in the riverine birds VC. |

| Candidate Valued Component, Intermediate Component, or Subcomponent | Rationale for Exclusion |
|---|---|
| Large mammals (Candidate Terrestrial Wildlife VC subcomponent) | <ul style="list-style-type: none"> • Large mammals, specifically black-tailed deer live in areas adjacent to the Project alignment (Burns Bog); however, monitoring of the existing collision impacts of Highway 99 by the Ministry of Transportation, and reporting in the Wildlife Accident Reporting System (WARS), indicates few to no deer impacts in the portion of Highway 99 to be upgraded as part of the Project. • In the five-year period between January 1, 2009 and December 31, 2013, there were three incidents involving deer within the Project. All three collisions occurred within a five-kilometre section of Highway 99 near the Highway 10 entrance. • Highway improvements associated with this Project are not anticipated to result in an increase in collision risk for large mammals. |
| Economic conditions (Candidate VC) | <ul style="list-style-type: none"> • Project-related effects are anticipated to be positive. • Influence of the Project will be considered in the context of project benefits in the Application, under Section 1.1.7 Economic Benefits |
| Growth and Growth Patterns (Candidate VC) | <ul style="list-style-type: none"> • Potential effects on growth can be effectively considered within the assessment of the Land Use VC |
| Recreation (Candidate VC) | <ul style="list-style-type: none"> • Potential effects on recreation can be effectively considered within the assessment of the following VCs: <ul style="list-style-type: none"> ▫ Land Use ▫ Marine Use |
| Connectivity and Community Cohesion (Candidate VC) | <ul style="list-style-type: none"> • The Project is anticipated to have an influence on connectivity and community cohesion. These effects are anticipated to be positive. <ul style="list-style-type: none"> ▫ The Project will introduce new cycling and pedestrian facilities, making walking and cycling between Delta and Richmond a viable transportation option for many people. ▫ The Project will expand the transit and HOV network, increasing the reliability of these transportation options for communities and area residents. ▫ The Project has the potential to affect positive changes in local street connectivity and access, travel times to employment and commercial areas, and access to community gathering or recreational areas and other services. • Effects of the Project on connectivity and community cohesion will be discussed under Section 1.1.8 Other Project Benefits. |
| Emergency Services (Candidate VC) | <ul style="list-style-type: none"> • The Project is anticipated to have a positive influence on emergency services. • Emergency response times and corridor reliability were identified as issues during consultation for the Project. Addressing congestion at the Tunnel will alleviate safety concerns, reduce emergency response times, and improve access for emergency responders. • Effects of the Project on emergency response times and service reliability will be discussed under Section 1.1.8 Other Project Benefits. |
| Utility, Infrastructure, and Other Services (Candidate VC) | <ul style="list-style-type: none"> • The Project is anticipated to have an influence on local utility, infrastructure and services. These effects are anticipated to be negligible and not result in a measureable change to local utility, infrastructure and services. • The workforce needed for the Project will largely be drawn from the Lower Mainland, which is not expected to result in any measureable increased pressure on residential utility demand in nearby communities. |
| Aviation (Candidate VC) | <ul style="list-style-type: none"> • Potential aviation-related effects of the new bridge will be subject to review by Transport Canada under sub-section 5.9(2) of the federal <i>Aeronautics Act</i>, R.S.C. 1985, c. A-2. The Ministry will complete an aeronautical obstruction clearance application and will conform to the required marking and lighting standards. • Aviation will not be studied as aviation-related effects are subject to review by another legislative body. |
| Climate Change (Candidate VC) | <ul style="list-style-type: none"> • Potential effects on greenhouse gas GHG emissions can be effectively considered under the assessment of Air Quality. |

APPENDIX B

“-” indicates no interaction

“✓” indicates potential interaction

4.1 River Hydraulics and River Morphology Assessment Highlights:

- The proposed bridge will have a clear-span over the Fraser River South Arm, which eliminates potential changes to river hydraulics or river morphology resulting from the new structure.
- The Fraser River South Arm is dynamic with scour in the order of several meters during freshet and migrating sand dunes with heights of up to four metres.
- Removal of the Tunnel is not expected to result in changes in water level or affect flow splits between the main channel and nearby channels.
- Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor.
- Tunnel removal is expected to result in temporary bed lowering between the Tunnel and the Lulu Island–Delta watermain; however, with monitoring and mitigation, no permanent effect on the watermain is expected.
- No Project-related long-term residual effects or cumulative effects on river hydraulics or river morphology are expected.

4.1 River Hydraulics and River Morphology

This section describes the existing conditions related to water levels, velocities, and flow patterns (river hydraulics), and their influence on sedimentation and erosion (morphology) within the Fraser River, as well as anticipated Project-related changes in such conditions. River hydraulics and river morphology is studied as an intermediate component (IC), and information on predicted Project-related change in river hydraulics and river morphology is used to support the assessment of effects of the Project on fish and fish habitat (**Section 4.4 Fish and Fish Habitat**), marine mammals (**Section 4.6 Marine Mammals**), and marine use (**Section 5.2 Marine Use**).

A technical volume, **River Hydraulics and River Morphology Study**, containing further detail on existing conditions and methodology used in predicting Project-related effects is included in **Section 16.2**.

4.1.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on river hydraulics and river morphology in terms of Project setting, and defines the assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

4.1.1.1 Assessment Context

Although no permanent instream works are required in the Fraser River, temporary impacts to river hydraulics and river morphology as a result of Tunnel removal have been examined because of their potential to affect fish and fish habitat, marine mammals, and marine use. Input received through consultation with government agencies, Aboriginal Groups, and the general public also informed the decision to undertake a river hydraulics and river morphology assessment. During pre-Application consultation on the Project, Metro Vancouver expressed an interest in the potential effect of Tunnel decommissioning on Metro Vancouver Water Services infrastructure (i.e. River Road West Main and Lulu Island-Delta Main). No other feedback or information, including Traditional Knowledge, that would be of specific relevance to the assessment of river hydraulics or morphology was received during pre-Application consultation.

Additional information on the selection of VCs, and the link between river hydraulics and river morphology, and receptor VCs is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**.

4.1.1.2 Methodology

The assessment of river hydraulics and river morphology follows the general methodology described in **Section 3.0 Assessment Methodology**. In early 2014, the Ministry initiated studies to meet the following key objectives:

- Understand the morphological evolution of the lower Fraser River and estuary and describe existing conditions.
- Assess potential changes in water levels, velocities, and flow patterns related to the Project.
- Assess potential Project-related changes in sediment deposition and erosion patterns.
- Assess potential adjustment of the riverbed profile following Tunnel removal.

4.1.1.3 Assessment Boundaries

Assessment boundaries for river hydraulics and river morphology are defined below.

Spatial Boundaries

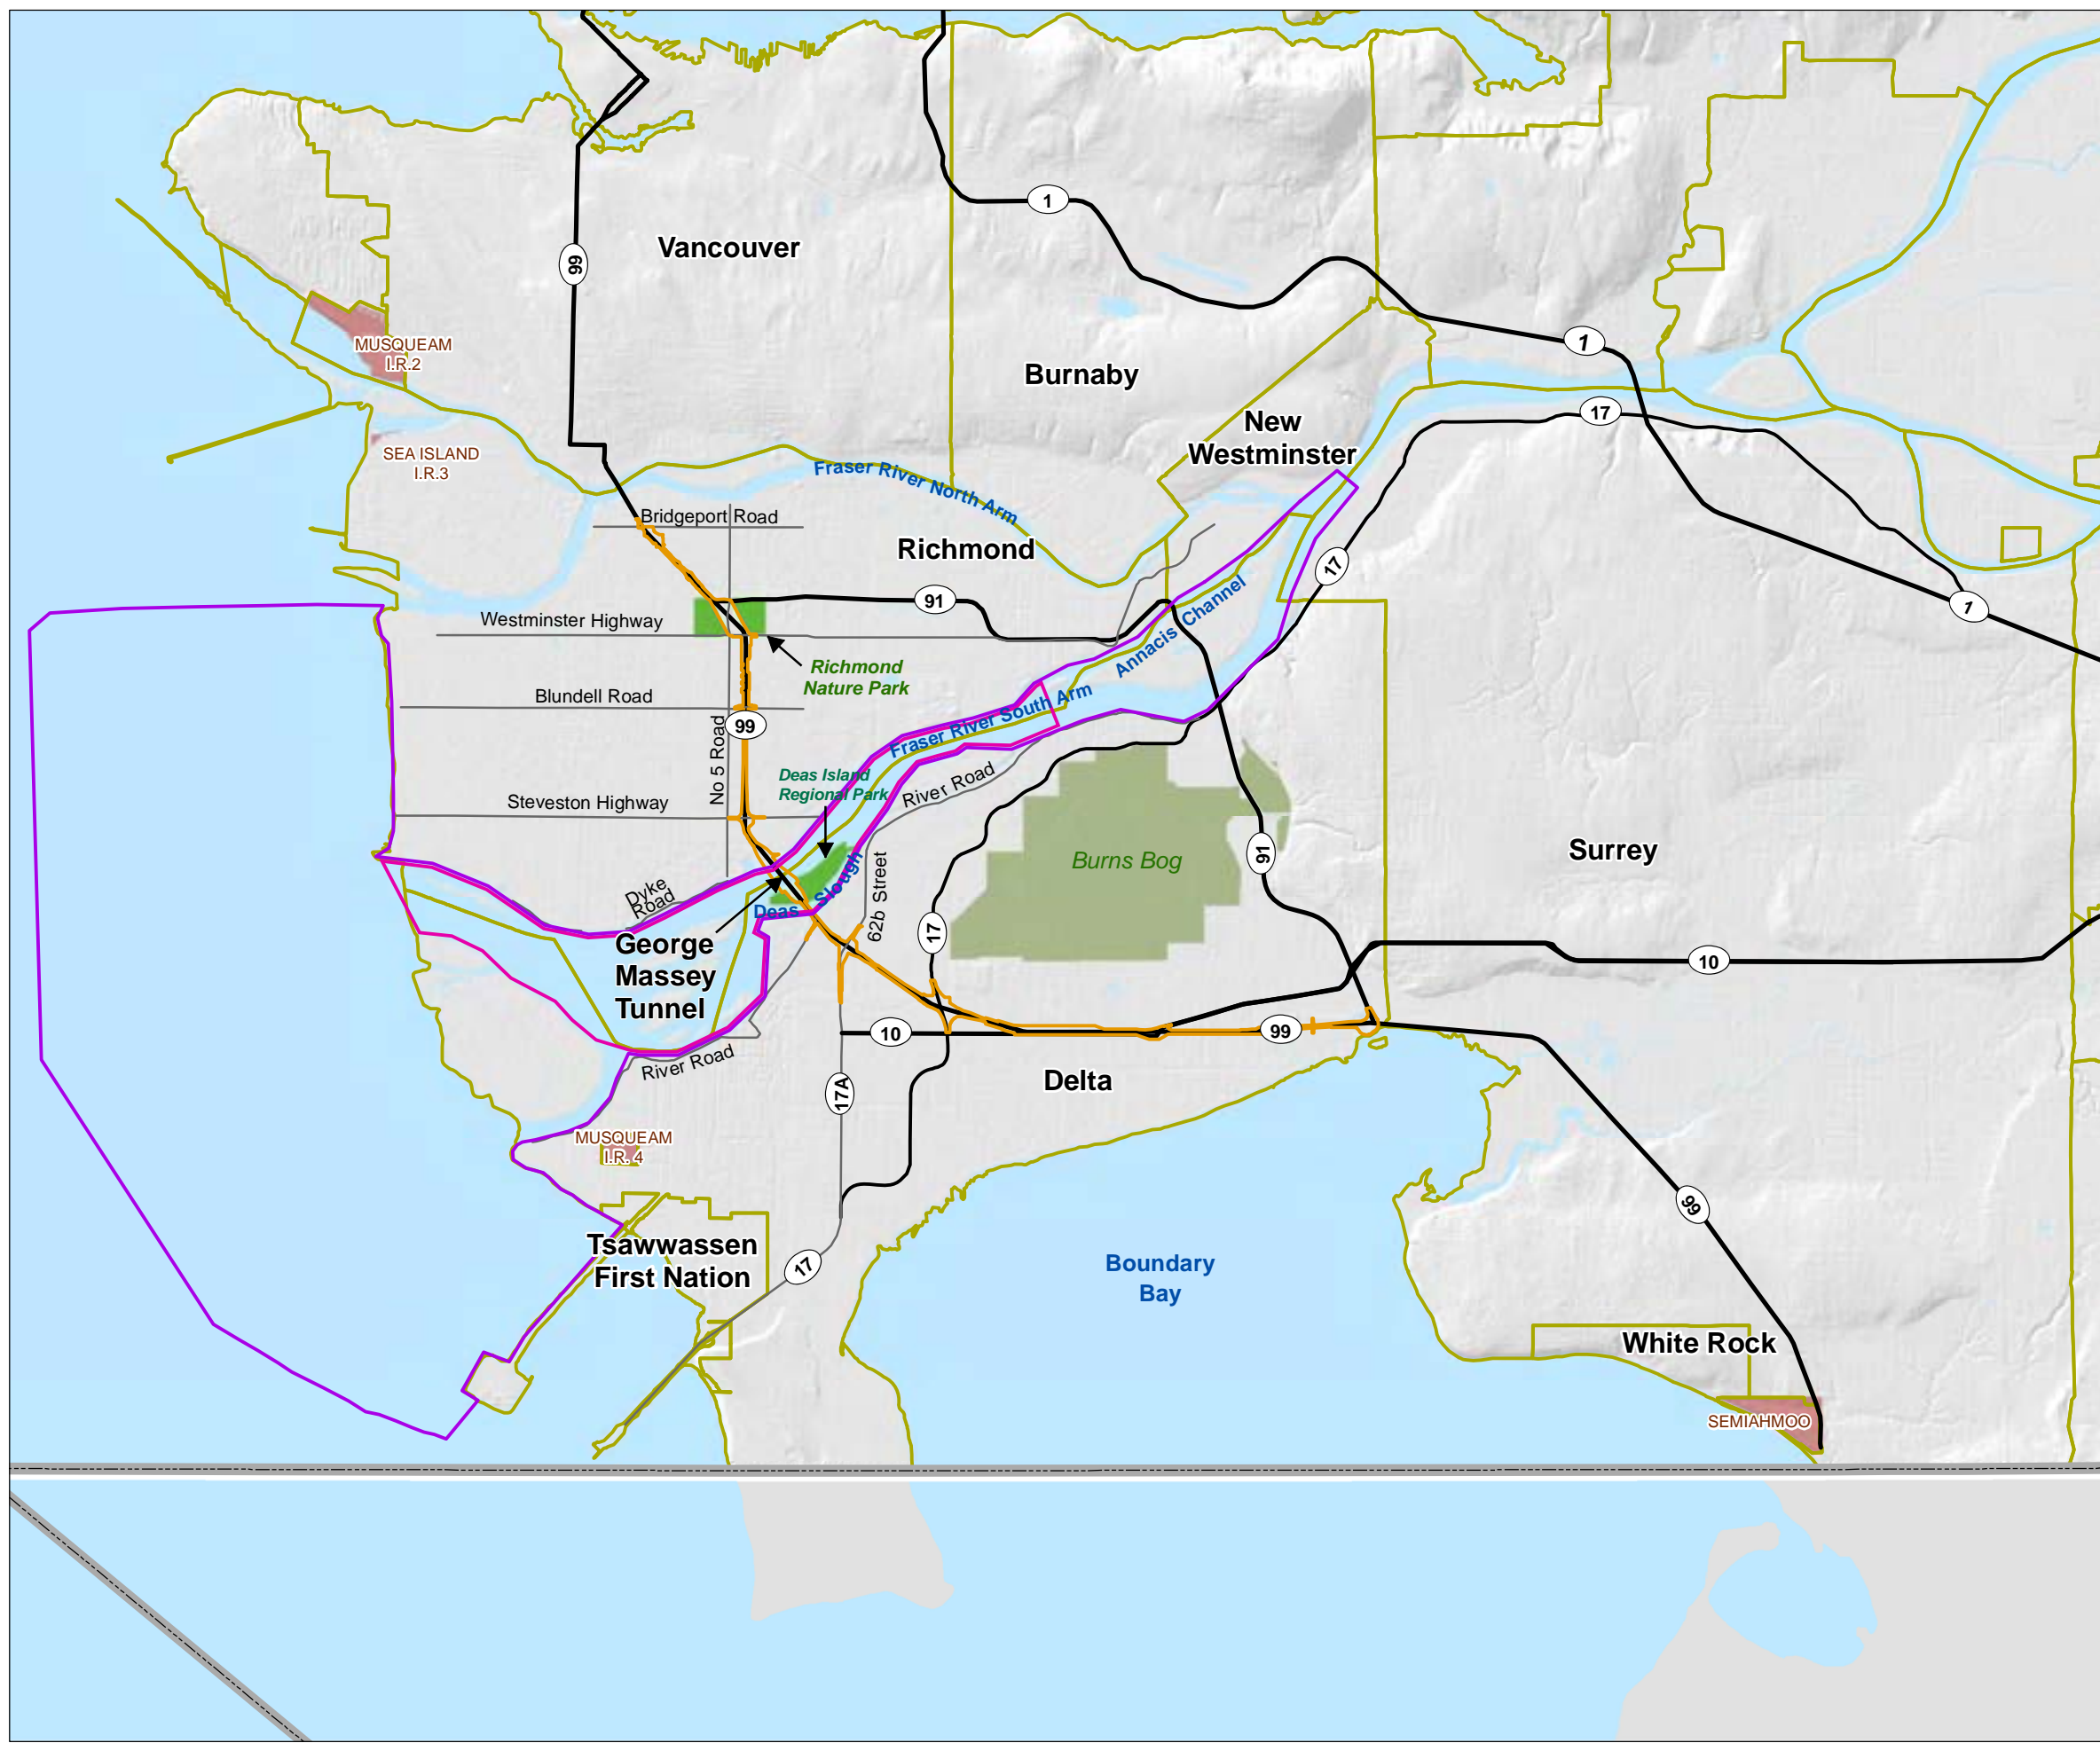

The local assessment area (LAA) includes the area where Project-related changes are likely to occur, and is defined as the Fraser River South Arm from just upstream of Tilbury Island to the mouth of the River, as shown on **Figure 4.1-1**.

The regional assessment area (RAA) is defined as the Fraser River South Arm, extending from just upstream of Annacis Island to the Fraser River estuary, including Sturgeon and Roberts Banks (**Figure 4.1-1**). While Project-related changes are not expected beyond the mouth of the Fraser River, the RAA incorporates the adjacent coastal waters to support tidal simulations and establish the boundary conditions for the numerical modelling used to predict Project-related effects.

Table 4.1-1 Spatial Boundaries for River hydraulics and river morphology Assessment

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|--|
| Local Assessment Area (LAA) | Fraser River South Arm from just upstream of Tilbury Island to the mouth of the River |
| Regional Assessment Area (RAA) | Fraser River South Arm, extending from just upstream of Annacis Island to the Fraser River estuary, including Sturgeon and Roberts Banks |

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on river hydraulics and river morphology were established based on the potential for each phase of the Project to interact with and have an effect on river processes. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, both the construction and operational phases of the Project include components and activities that could interact with and affect river processes within the Fraser River South Arm; therefore, the following temporal boundaries were defined for assessment of river hydraulics and river morphology:

- Existing conditions.
- Construction phase (including decommissioning of the Tunnel).
- Operations phase (new bridge and highway in operation).

Temporal characteristics of the Project phases are discussed in **Section 1.1 Description of Proposed Project**. Specific temporal considerations for the assessment of river hydraulics and river morphology and its sub-components are discussed in the context of Project interactions and potential effects in **Section 4.1.3 Potential Effects**.

Administrative Boundaries

No administrative boundaries have been identified that could impose limitations on the assessment of potential Project-related effects on river hydraulics and river morphology.

Technical Boundaries

Technical boundaries for predicting changes to river hydraulics and river morphology exist due to the interpretive nature of geomorphic studies and the limitations of the numerical methods used to model river hydraulics and river morphology. This uncertainty has been mitigated to some extent by using accurate data collection methods and by relying on data that were collected reliably by others.

The numerical modelling approach is consistent with standard practices and state of the science. Details of model validation are given in the technical volume, ***River Hydraulics and River Morphology Study*** included in **Section 16.2**.

4.1.2 Existing Conditions

This section provides an overview of the methodology used for collecting baseline data, and describes the existing conditions pertaining to current distributions, water levels and sedimentation patterns in the assessment areas. An overview of the regulatory context for management of surface water as relevant to the Project is also provided.

4.1.2.1 Baseline Data Collection

An interpretive geomorphology approach that involved the following tasks was used to collect baseline data and to understand the morphological evolution of the lower Fraser River and estuary:

- Literature review – Previous field, model, and theoretical studies were reviewed to understand the environment and driving forces at work near the Tunnel and interpret the results of the numerical modelling in this light.
- Aerial photograph interpretation – Aerial photographs of the LAA spanning the years 1938 to 2009 were analyzed. These provide insight into the planform changes that have taken place on the lower Fraser River since 1938 and the role of natural or man-made factors in driving these changes.
- Bathymetric surveys – Watermain crossings on the Fraser River have been surveyed regularly by the Greater Vancouver Water District since 1962. Data were also obtained from bathymetric surveys of the lower Fraser River conducted in 1988/89, 2000/01, 2008/09 and 2014 by Public Works and Government Services of Canada (PWGSC).

4.1.2.2 Regulatory Context

Two pieces of legislation are relevant to the Project in the context of river hydraulics and river morphology: the B.C. *Water Sustainability Act* S.B.C. 2014, c. 15, and the federal *Fisheries Act*, R.S.C. 1985, c. F-14.

In B.C., the ownership of water is vested in the Crown as stated in Section 5 of the *Water Sustainability Act*, the primary provincial statute regulating water resources. Since the Project involves works in or about the Fraser River, Sections 11 and 12 of the *Water Sustainability Act* and associated *Water Sustainability Regulation* B.C. Reg. 36/2016 would apply to such activities. Section 46 of the *Water Sustainability Act* regulates the introduction of foreign matter into streams. The *Water Sustainability Regulation* addresses the requirements to allocate surface water (e.g., application requirements) and identifies the requirements for using water or making changes to a stream in accordance with the regulation.

Fisheries Act

Section 35 (1) of the *Fisheries Act* regulates “any work, undertaking or activity that results in serious harm to fish that are part of a commercial, recreational or Aboriginal fishery, or to fish that support such a fishery.” Section 36 (3) regulates depositing or permitting the deposition of “a deleterious substance of any type in water frequented by fish”. A deleterious substance may include excess concentrations of suspended sediment.

4.1.2.3 Existing Conditions

George Massey Tunnel

The Tunnel is located on the Fraser River South Arm between km 18 and km 19 from Sand Heads (**Figure 4.1-2**). It is 629 m long and consists of six concrete segments (105 m long each). Tunnel width and height are 23.8 m and 7.3 m, respectively. The Tunnel configuration is shown in **Figure 4.1-3**.

The Tunnel is protected from scour by a rock apron and a flexible concrete mattress (**Figure 4.1-4**). The top of this scour protection layer was constructed to be flush with the riverbed in the centre channel. The elevation of the top of the Tunnel’s scour protection relative to the river bottom is shown in the as-built surveyed Tunnel cross sections provided in **Figure 4.1-5** and river bathymetry is shown in **Figure 4.1-6**.

Figure 4.1-6 Riverbed Elevations from Bathymetric Survey Data Collected on April 2, 2014.

Fraser River Flows and Sediment Loads

The Fraser River South Arm is a single, meandering, sand-bed channel. Fraser River flows are dominated by snowmelt, with discharge typically rising in April, peaking between May and July during freshet, and receding during autumn and winter. Average peak flow of the Fraser River at Hope is about 7,000 m³/s in June and average low flow is approximately 850 m³/s in March (NHC 2002).

Sediment loads on the lower Fraser River range from 12.3 to 31.0 million tonnes/year (average 16.5 million tonnes/year) (1965-1986 data; McLean et al. 1999, NHC 2002). Fine sediments (i.e., washload) generally remain in suspension and have little effect on sedimentation patterns. In contrast, bed-material load (i.e., bedload or sediment load that gets deposited in the river) influences river morphology. In the lower Fraser River, bedload ranges from 1.2 million to 8.9 million tonnes/year (average 2.9 million tonnes/year; NHC 2002).

Dunes, characteristic features of a sand-bed channel, occur on the riverbed within a 1.2 km stretch centered over the Tunnel. Large dunes have also been observed from the Port Mann Bridge to the mouth of the river (NHC 2009). Dune height varies from 0.5 m to 2.0 m in approximately 12 m depth, although individual dunes can be considerably larger (Church and McLean 1994). As bedload sediments are transported downstream, dunes generate periodic scour and fill, and can increase total scour depths, damaging scour protection aprons and rock protection.

Flow in the lower Fraser River is influenced by a salt water wedge. The location of the salt wedge moves throughout the day in response to tide height variations, and seasonally in response to river discharge variations. The maximum upstream extent of salt water intrusion is about 30 km from the mouth during winter low flows and less than 15 km during freshet (Ward 1976). The salt wedge influences patterns of sediment entrainment and deposition, with rapid deposition occurring as the salt wedge migrates upstream, and re-entrainment as the salt wedge recedes (Kostaschuk and Luternauer 1989).

Water Levels

The river is tidally influenced. Tides in the Strait of Georgia are generally characterized by two highs and two lows of unequal height every lunar day (i.e., every 24 hours and 50 minutes). Greatest tidal amplitudes exceed 3.5 m from April to July and from October to January. At Deas Island, tides are moderated by Fraser River flows, and normal water levels range between minus 1.8 m (Canadian Hydrographic Service chart datum) and 2 m (Canadian Hydrographic Service high water datum). Extreme water levels in the Fraser River estuary are governed by

high tides and storm surge in the winter, rather than high discharges during freshet. Annual minimum water levels in the lower Fraser River have exhibited a downward trend between 1969 and the late 1980s, likely due to lowering of the riverbed.

In-River Utilities and Infrastructure

Utilities, including pipelines, that currently cross the Fraser River downstream of New Westminster include: six watermains, four natural gas pipelines, and one oil pipeline (**Figure 4.1-2**). Scour protection aprons at a number of these crossings create grade controls that affect riverbed elevations. The Lulu Island–Delta watermain, the pipeline nearest to the Tunnel, is located approximately 600 m downstream. It has a scour protection apron over its southern half, which imparts a variable cross-channel elevation. Bathymetric surveys show considerable scour and bed degradation up and downstream of the Lulu Island-Delta main crossing.

Bridge crossings in the reach include the Pattullo Bridge, opened in 1937; the Port Mann Bridge, originally opened in 1964 and replaced in 2012; and the Alex Fraser Bridge, opened in 1986 (**Figure 4.1-2**). The Skybridge just downstream of the Pattullo Bridge was constructed between 1987 and 1989.

Extensive river training and bank protection works, undertaken since 1910, along the Fraser River South Arm have led to narrowing and deepening (McLean et al. 2007), as well as lengthening of the river channel by approximately nine kilometres in a seaward direction.

Banks of the lower Fraser River have been hardened over the years by extensive riprap protection. The banks of Woodward Island were riprap-armoured on the main channel side between 1927 and 1941. By 1953, most of the right¹ bank of the Fraser River from Steveston to upstream of the Tunnel was protected with riprap (Pretious and Thorne 1953). The bank of Deas Island on the main channel side has also been protected with riprap, although the time of construction is not known.

¹ In hydrology, left bank and right bank are relative to an observer looking downstream.

Dredging

Annual dredging, conducted by Vancouver Fraser Port Authority, in the Fraser River South Arm has been extensive since 1960 and concentrated mostly downstream of New Westminster. Dredging volumes were greatest between 1976 and 1990, then declined through the following decade. During the height of dredging activity, about 15% of the total annual sediment removal on the Fraser River was from Gravesend Reach, upstream, and Woodward Reach, downstream, of the Tunnel (**Figure 4.1-2**). At Gravesend Reach, large-scale navigation and borrow dredging had a noticeable effect on bed levels. Bed lowering along Gravesend Reach occurred at a rate of about 25 cm/year, when dredging volume reached 700,000 m³/year during the 1980s, and remained relatively constant when dredging volume was in the order of 200,000 m³/year (NHC 2002). Although total removals have rebounded since 2001, less than one per cent of total dredging has been extracted from Gravesend Reach annually.

Dredging for maintenance of the navigation channel occurs annually at the mouth of the Fraser River, especially in Steveston Cut (**Figure 4.1-2**). Infrequent dredging of secondary channels occurs in Ladner Reach and Sea Reach to improve navigation for small vessels (FREMP 2006). Since 2004, the maximum vessel draft in the reaches downstream of Deas Island (Woodward Reach, Ladner Reach, Sea Reach, Canoe Passage, Steveston Cut, and Sand Heads Reach) has been increased from 10.7 m (in place since 1976) to 11.5 m (FREMP 2006).

Long-Term Changes in River Channel Configuration

Historically, the Fraser River estuary has been very active morphologically. The river transports large volumes of sand to the reach, where patterns of deposition, mobilization, and transport are heavily influenced by the tides. As a result, the configuration of channels at the river mouth is complex and in the absence of human intervention would be in constant flux. As late as 1898, Ladner Reach was considerably larger than its current size. Around 1827, the main channel occupied Ladner Reach and continued along Sea Reach to the mouth. Prior to this, the main flow path may have been along Canoe Passage via Ladner Reach. The Ladner Reach entrance was observed to have widened, and the deepest portion of the channel migrated from right to left bank at Deas Island in the years prior to Tunnel construction (Pretious and Thorne 1953).

Historic aerial photographs of the lower Fraser River, from 1938 to 2009, reflect increasing anthropogenic development over time along the river and on its floodplain. There has been no major shifting in the banklines over the 60-year period, due in large part to bank hardening (i.e., riprap) and river training works. Minor distinguishable changes are attributed to dredging of Deas Dock and some expansion of industrial water lots in the Steveston area.

Banklines of mid-channel islands, particularly of the Woodward Island complex, are largely unprotected, and therefore more likely to change over time. Mid-channel islands have expanded since 1949. In particular, expansion of Little Hart Island between 1949 and 1974 occurred due to dredge spoil dumping and transport by currents (Hay & Company Consultants Inc. 2010). This expansion appears to have forced the flow at the elbow of Ladner Reach north into Barber Island. The main channel of the reach has since shifted north of Little Hart and Big Hart islands, while the south channel has become constricted. Downstream in Sea Reach, the width of the southern portion of the channel has not changed appreciably, but the reach downstream of the confluence with Woodward Slough appears to have widened between 1949 and 2009.

A sand bar located approximately 1.5 km upstream of the Tunnel, at the downstream end of Tilbury Island, was first observed in the 1954 aerial photograph. Favourable tides allowed observation of it again in the 1984 photoset, by which time the bar/island had started to become colonized by vegetation, presumably due to vertical sediment accumulation. The bar/island is still present today, with roughly three-quarters colonized by marsh vegetation.

Between 1898 and 1953, the upstream end of Kirkland Island was subject to considerable erosion (Pretious and Thorne 1953). The bankline at the downstream end of Deas Island also receded mostly between 1948 and 1953. Since 1953, banklines upstream of Kirkland Island and Deas Marsh have largely stabilized.

Aboriginal Groups have noted that the Fraser River channel is shifting and causeway changes could have substantial effects, especially on saltwater marshes.

Long-Term Changes in River Profile

Changes in the profile of the riverbed within the LAA over time were assessed using historical PWGSC bathymetry survey data collected for the years 1988/89², 2000/01, 2008/09, and 2014³. In general, there has been a trend towards bed lowering. Riverbed profiles between the river mouth and Port Mann Bridge, and within one kilometre upstream and downstream of the Tunnel, show an average annual rate of lowering of around 10 cm/year (overall bed lowering by 1.5 m to 3.5 m) between 1988/89 and 2014. At the Lulu Island–Delta watermain crossing downstream of the Tunnel, the bed lowered by as much as 2.5 m between 1981 and 1997.

² Data are missing for the upstream portion of Ladner Reach and a section between Annacis Island and Tilbury Island.

³ Survey data from Ladner Reach were not available at the time of analysis.

Scour protection was added to the Tunnel in 2000, resulting in the profile appearing to have risen between 1997 and 2011. Degradation of 0.5 m to 1.0 m occurred again between 2011 and 2013. At the Tilbury watermain crossing upstream of the Tunnel, the bed scoured by 2.5 m to 3.0 m between 1990 and 1997. As a result of scour protection added in 2001/2002, the profile was higher in 2008 than in 1997. From 2002 to 2008, only about 0.5 m of scour was observed at this crossing.

The trend toward bed lowering is consistent with previous findings of long-term riverbed degradation downstream of New Westminster. Between 1951 and 1988, average bed levels in the channel lowered by two to three metres (NHC 2002), with the greatest bed lowering occurring in the 1980s. This is consistent with the period when the rate of sediment removal routinely exceeded the incoming bed material load. Since the mid-1990s the rate of bed lowering has slowed considerably, or actually reversed in some years at a few locations due to the reduced dredging effort (McLean et al. 2006). Since 2004, sediment removal volumes have increased in the lower reaches resulting in a 0.8 m decrease in bed level

A detailed description of changes in riverbed elevations over time within the assessment area is provided in **Section 5.2** of the technical volume, *River Hydraulics and River Morphology Study*, included under **Section 16.2** of the Application. Historical river profiles and cross-sections used to identify trends in river profile, as discussed above, are shown on **Figures 5-2 to 5-5** of this technical volume.

4.1.3 Potential Effects

This section discusses anticipated interactions of Project components and activities with river hydraulics and river morphology, and potential effects of such interactions. Information on mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 4.1.4**. Potential for residual effects (i.e., effects remaining following the implementation of mitigation measures) is described in **Section 4.1.5**. A discussion of the potential for cumulative effects on river hydraulics and river morphology is presented in **Section 4.1.6**.

4.1.3.1 Project Interactions

An overview of potential interactions between Project activities and river processes during the construction and operation of the Project is provided in **Appendix A**. A preliminary evaluation of the potential effects of Project interactions on river hydraulics and river morphology, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Construction: The new bridge will be a clear-span and as such there will be no impact to river hydraulics and river morphology from the new bridge.

Upgrading of the existing shoreline riprap protection may be required at completion of bridge construction. These upgrades would be limited to placement of clean rock on the existing armoured slope (i.e. no instream excavation and no river training works) and would have little or no effect on river hydraulics or river morphology.

On the Richmond side of the river the existing provincial dike will be reconstructed and upgraded to current standards where it is impacted by the Project. This work will be carried out on shore and as such there will be no impact to river hydraulics and river morphology from this activity.

Green Slough will be realigned to a configuration closer to its pre-Highway 99 alignment. Currently, the slough turns sharply north at the highway embankment, before connecting with Deas Slough south of the crossing. The realigned slough will continue east beneath the bridge and connect with Deas Slough east of the highway, similar to pre-highway conditions. Realignment of Green Slough is not expected to have any effects on hydraulics or morphology in Deas Slough or the South Arm of the Fraser River. Proposed enhancements to estuarine and riparian habitat would provide a net benefit compared with existing conditions.

Tunnel removal and associated activities are expected to involve temporary riverbed disturbance and consequent re-suspension of sediments in the Fraser River South Arm as well as potential local scour. Removal of the Tunnel from the river bed and infilling of the trench left behind could also influence current velocities, water levels, movement of salt water, and flow splits in the Fraser River South Arm. This is discussed further in **Section 4.1.3.2**.

Operation: Given that the new bridge will have a clear span across the Fraser River South Arm, activities associated with Project operation, including routine maintenance, have no interaction with river hydraulics and river morphology.

Removal of Tunnel segments would have a temporary influence on river processes for approximately 210 days during the operational phase of the Project, while the trench left by the Tunnel gets filled in by sediments carried naturally in the river. This is discussed further below.

4.1.3.2 Potential Effects

Potential effects of the Project on river hydraulics and river morphology in the lower Fraser River were investigated using the TELEMAC-MASCARET (TELEMAC) modelling system.

The accuracy and results of the hydraulic modelling needs to be viewed in the context of the very dynamic morphology of the Fraser River, interpretive nature of geomorphic studies and the limitations of the numerical methods used to model river hydraulics and river morphology. The dynamic nature of the river morphology is illustrated by the fact that records at the Tunnel show that temporary scour during freshet can be in the order of several meters and migrating sand dunes with heights of up to 4 m are not uncommon.

With numerical modelling, there is uncertainty with respect to predictions of river currents and sediment transport. In this context, results presented on projected bed-level evolution should be interpreted as one of the reasonably possible outcomes.

The TELEMAC system, made up of a suite of finite element computer programs developed by the Laboratoire National d'Hydraulique et Environnement (LNHE), is an internationally-recognized modelling tool, with more than 4,000 registered users including BC Hydro, Hydro-Québec, and Canadian Coast Guard, as well as universities, engineering schools, and research centres.

The TELEMAC programs utilized for this study include the following:

- TELEMAC3D – A three-dimensional hydrodynamic model that solves the time-dependent Navier-Stokes equations with an evolving free surface, under the assumption of hydrostatic or non-hydrostatic pressure distribution using the finite element method.
- SISYPHE – A sediment transport and morphodynamic model that computes bed-load and suspended load separately, and the resulting bed changes using the Exner equation.

The hydrodynamic program TELEMAC-3D was used to compute hydraulic conditions in the lower Fraser River. Scour and deposition around the Tunnel were computed by coupling the sediment transport and morphodynamic model SISYPHE to TELEMAC-3D. The new bed elevation computed by SISYPHE was then fed back into TELEMAC-3D to re-compute the flow hydrodynamics, as illustrated in **Figure 4.1-7**. The resulting model serves as a tool for understanding potential changes to river hydraulics and river morphology due to Tunnel removal.

Future changes in physical inputs, such as sea level rise, changes to hydrograph timing and shape, sediment supply, and alterations to the river channel, will influence future hydraulics and morphology in ways that cannot be predicted by the model. Rather, the model captures the most important physical processes in the lower Fraser River and assists in predicting the consequences of a specific change to the system, and model results are interpreted in the context of known river behaviour, using professional judgement.

Figure 4.1-7 TELEMAC Model Coupling Flow Diagram

Model analyses were conducted to examine the following two scenarios:

1. Trench infilling – Short-term channel response to the removal of the Tunnel, particularly trench migration and infilling including review of potential effects on nearby infrastructure and habitat.
2. Post-trench infilling – Potential long term effects of Tunnel removal on river hydraulics and sedimentation patterns after the trench has infilled by deposition of river sediments.

The results of these analyses are presented below. Details on modelling methodology, including model geometries, boundary conditions, and calibration and validation, as well as detailed results of model simulation are presented in the technical volume, *River Hydraulics and River Morphology Study*, included under **Section 16.2**.

Sediment Generation and Deposition

Tunnel removal will require removing the rock apron and concrete mattress, excavating the fill that was placed adjacent to the Tunnel segments when it was built, floating the pre-cast concrete Tunnel segments to the surface and towing the segments off site for recycling. It is expected that several months will be required to remove the four middle sections of the Tunnel.

The minor changes in current velocities during Tunnel removal are not expected to result in bank erosion, barriers to fish migration or impediments to marine traffic. Depositional changes resulting from re-suspension of sediments during Tunnel removal are expected to be minimal.

These activities will generate suspended sediment. The effect of sediment generation will depend on the ambient suspended sediment concentrations at the time of removal. It is assumed Tunnel removal will commence in mid-summer, after it is anticipated that freshet flows have receded, and will continue into the winter low-flow period.

Based on the volume and expected nature of the sediment and sand fill overlying the Tunnel, the temporary increase in suspended sediment volume due to the Tunnel removal activities is estimated to range from one per cent to nine per cent over ambient volumes between August and December. In the context of the natural seasonal and annual variability of suspended sediment, this expected increase in suspended sediment volume is considered low. Further detail on predicted increase in suspended sediment as a result of Tunnel removal is provided in Section 8.1.2.2 of the technical volume, *River Hydraulics and River Morphology Study*, included as **Section 16.2** of this Application.

Suspended fine sediments generated during Tunnel removal would be transported to the Strait of Georgia before deposition could occur. Since the incremental volume of suspended sediment generated during Tunnel removal is expected to be small in comparison with the ambient load, and washload is mostly transported beyond the tidal flats at the river mouth, no noticeable effects on deposition in the Strait of Georgia are expected.

Local scour and deposition are expected during Tunnel removal due to flow acceleration around exposed edges of Tunnel segments. The segments are expected to be removed in sequence. Flow will accelerate around the exposed ends and entrain sediment, which would then be deposited downstream. The degree of sediment transport associated with local flow accelerations during construction will depend on time of year and associated current velocities. These effects are expected to be temporary and small in scale compared with overall bed material transport.

With the implementation of standard best management practices, such as the use of washed rock with no fines or debris, upgrades to the existing riprap bank protection along the shorelines are not expected to generate noticeable amounts of suspended sediment.

Current Velocities

Tunnel removal is predicted to result in a minor reduction of surface water velocity of between 0.3 m/s and 0.5 m/s. The corresponding reduction in near-bed velocities (Elevation -12 m GSC) is expected to be between 0.1 m/s and 0.4 m/s. The region that will experience this reduction extends from the Tunnel to about 50 m downstream.

Further detail on modelled current velocity distributions following Tunnel removal is provided in **Section 7.4.1.1** of the technical volume, *River Hydraulics and River Morphology Study* included in **Section 16.2**.

Water Levels

Based on hourly water levels modelled at several stations upstream and downstream of the Tunnel, post-infilling water levels are indistinguishable from the natural variability of the river system.

Details on the modelling results for water levels are provided in **Section 7.4.1.2** of the technical volume, *River Hydraulics and River Morphology Study* included in **Section 16.2**.

Flow Splits

The Fraser River South Arm divides just below Deas Island (18 km upstream from the Strait of Georgia) into Ladner Reach, and then again into Canoe Passage. The flow split between Woodward Reach and Ladner Reach was calculated from the results of flow modelling. Results of these calculations indicate that the predicted change in the flow splits were within the range of natural variability and as such removal of the Tunnel is not expected to have an effect on the flow split between Woodward Reach and Ladner Reach. This suggests that Tunnel removal is not likely to result in the expansion of Ladner Reach through erosion of Deas Island or the nose of Kirkland Island.

Details on flow split calculations are provided in **Section 7.4.1.3** of the technical volume, *River Hydraulics and River Morphology Study* included in **Section 16.2**.

Trench Infilling and Migration

Hydraulic modelling indicates that there will be a decrease in river flow velocity and consequent sediment deposition over the deeper trench region when the Tunnel segments are removed. Modelling shows that the trench would be almost completely infilled in approximately 210 days.

Model results indicate that the trench will migrate downstream as it infills. **Figure 4.1-8** shows a time-series of the bed profile along the centreline of the navigation channel over a trench-infilling simulation period of 210 days. **Figure 4.1-9** shows the change in riverbed elevation 210 days after Tunnel removal as compared with existing conditions. At the end of 210 days the trench is mostly filled in, but the riverbed between the Tunnel and the Lulu Island–Delta watermain has lowered by one to two metres. This lowering is expected to be temporary. It is most likely caused by sediment being “trapped” by the trench, resulting in less sediment available to replenish the downstream bed.

Figure 4.1-8 Riverbed profile along the centreline of the navigation channel after tunnel removal.

Figure 4.1-9 Change in riverbed elevation 210 days after Tunnel removal as compared with existing conditions

Expected changes in riverbed profile beyond the trench footprint are in the same order as normal variation in bed levels in the lower Fraser River.

Details on model simulations of riverbed elevations during trench infilling are provided in **Section 7.3.2** of the technical volume, *River Hydraulics and River Morphology Study* included in **Section 16.2**.

Post-Trench Infilling Morphological Changes

As noted under “Technical Boundaries” in **Section 4.1.1.3** there is uncertainty with respect to predictions of river currents and sediment transport given the limitations of numerical modelling, and the highly complex and dynamic nature of the Fraser River morphology at the Project site. In this context, results presented on projected bed-level evolution should be interpreted as one of several possible outcomes.

Near-field (fine resolution) modelling results indicated bed lowering 150 m upstream and downstream of the Tunnel for existing and post-trench infilling scenarios. However the magnitude of lowering was about 0.5 m to 1.0 m less for the post-trench infilling case. In other words, bed levels are expected to increase on average by 0.5 m to 1.0 m in this region (**Figure 4.1-10**). This change will likely result in less sediment available to be deposited in the channel downstream between the Tunnel and Lulu Island–Delta watermain, contributing to bed lowering in that segment.

Figure 4.1-10 Change in river bed elevation during freshet after Tunnel removal as compared with existing conditions

Far-field modelling suggests river bed elevation changes as a result of Tunnel removal are limited to 500 m upstream and 1,500 m downstream of the Tunnel. In this region, deposition of about 0.5 m in the middle of the channel and scour of 0.5 m to 1 m at the margins could be expected. Negligible changes (less than ± 0.05 m) are predicted to occur to the bed levels adjacent to Tilbury Island.

The majority of suspended fine sediments generated during Tunnel removal would be transported to the Strait of Georgia before deposition could occur. Minor deposition could occur in slower moving areas such as channel margins and sloughs. Since the incremental volume of suspended sediment generated during Tunnel removal is small in comparison with the ambient load, and washload is mostly transported beyond the tidal flats at the river mouth, no noticeable effects on deposition in the Strait of Georgia are expected.

4.1.4 Mitigation Measures

Potential Project-related changes that require mitigation consideration are: anticipated minor increase in volume of suspended sediment during Tunnel decommissioning activities, and riverbed lowering between the Tunnel alignment and the Lulu Island-Delta watermain for one to two years after Tunnel removal. As discussed in **Section 4.1.3.1**, other potential Project-related changes in river flow and sedimentation patterns are negligible or minor.

Mitigation measures to address potential effects associated with increases in volume of suspended sediments are discussed in **Section 4.4 Fish and Fish Habitat**. Mitigation measures to address potential effects associated with temporary Project-related changes in river bed elevations are presented below.

Temporary changes to downstream river bed elevations after Tunnel removal have the potential to affect the Lulu Island-Delta watermain. The following measures are proposed to mitigate these effects:

- Early engagement and coordination, during planning of the proposed decommissioning works, with Metro Vancouver (owner of the watermain). Engagement would continue through the construction and post-construction periods until confirmation that potential effects on the existing watermain have not occurred or have been appropriately mitigated.
- Development of a mitigation plan in conjunction with Metro Vancouver, which is anticipated to include the following:
 - Monitoring of riverbed within 100 m upstream and downstream of the watermain. Regular monitoring at appropriate intervals will begin during Tunnel removal. Monitoring frequency may be revised following Tunnel removal, based on a review and evaluation of monitoring results by a qualified registered professional (QRP). If a lowering of the edges of the scour protection apron is noticed, the scour protection aprons will be upgraded under the direction of a QRP.
 - Stockpiling of appropriately-sized rock near the Project site, for priority scour protection repairs at the watermain crossing.

- Establishment of on-call contracts with a QRP and a qualified marine contractor prior to Tunnel removal, to ensure that scour protection repairs can be designed and implemented on short notice if required. The on-call QRP and contractor will have relevant experience in scour protection for water crossings.

The mitigation measures described above involve commonly applied methods that have proven to be effective in protecting the existing infrastructure against scour, and are expected to have a high degree of success in ensuring potential effects on the Lulu Island/Delta watermain are avoided.

4.1.5 Residual Effects

Residual effects are those that remain following implementation of mitigation measures. Potential residual effects on river hydraulics and river morphology considered further in this assessment are:

- Suspended sediment generation during Tunnel removal: Tunnel removal activities are expected to result in a temporary increase in the volume of suspended sediment in the Fraser River South Arm.
- Temporary bed lowering between the Tunnel alignment and the Lulu Island-Delta watermain: Based on results of modelling, temporary changes to the river bed elevation, which could persist for one or two freshets, are expected between the Tunnel and the Lulu Island–Delta watermain after Tunnel removal.

The above effects are characterized in terms of the direction, magnitude, extent, duration, frequency, reversibility, and likelihood of each anticipated residual effect. Definitions for ratings applied to residual effects criteria, developed with specific reference to river hydraulics and river morphology are presented in **Table 4.1-2**. A summary of criteria ratings for the potential residual effects is provided in **Table 4.1-3** and **Table 4.1-4**.

Context: Context for the characterization of residual effects, i.e. sensitivity/resilience of hydraulics and morphology of the river to potential Project-related effects, based on existing conditions, has been taken into account in characterizing the residual effects. This includes the typically high volumes of sediment load transported by the Fraser River South Arm, wide variation in suspended sediment concentrations on a seasonal and annual timescale, and seasonal changes and the passage of dunes on the riverbed, which regularly induce changes in elevation greater than 2 m.

Table 4.1-2 Criteria Used to Characterize Residual Effects on River Hydraulics and River Morphology.

| Criteria | Description | Definition of Rating | |
|-----------|--|----------------------|---|
| Direction | Overall nature of the residual effect | Adverse | Negative effect as a result of the Project. |
| | | Positive | Beneficial effect as a result of the Project. |
| | | Neutral | Neutral effect as a result of the Project. |
| Magnitude | Intensity of the effect relative to natural or baseline conditions | Negligible | No measurable change to river hydraulics or morphology |
| | | Low | A measurable change within the range of natural variability, but not affecting aquatic habitat, navigability, or infrastructure. |
| | | Moderate | A measurable change within or outside the range of natural variability, and may pose a moderate risk to aquatic habitat, navigability, or infrastructure. |
| | | High | A measurable change outside the range of natural variability and may affect long-term viability of aquatic habitat, navigability, or infrastructure. |
| Extent | Geographic extent / distribution of the residual effect | Site | Effect is restricted to the immediate Project alignment. |
| | | Local | Effect is restricted to the LAA. |
| | | Regional | Effect is restricted to the RAA. |

| Criteria | Description | Definition of Rating | |
|---------------|---|----------------------|--|
| Duration | Length of time over which the residual effect is expected to persist | Transient term | Effect occurs once during Project construction or operation. |
| | | Short term | Effect occurs during a limited period of days to weeks during Project construction. |
| | | Moderate term | Effect persists over a period of weeks to months. |
| | | Long term | Effect persists over several years. OR Change is permanent. |
| Frequency | Nature of the occurrence of the residual effect (e.g., how often the stressor affects the IC) | Rare | Effect occurs once during Project construction or operation. |
| | | Uncommon | Effect occurs intermittently during Project construction or operation. |
| | | Frequent | Effect occurs frequently during Project construction or operation. |
| | | Continuous | Effect occurs continuously during Project construction or operation. |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after the disturbance has ceased (or after a period of time after the disturbance has ceased) | Reversible | Baseline conditions will be naturally restored after disturbance has ceased. |
| | | Irreversible | Baseline conditions will not be naturally restored after disturbance has ceased. |
| | | Change | Effect may fluctuate between positive and adverse for the duration of the disturbance. |
| Likelihood | Likelihood that the residual effect may occur | Low | Likelihood of residual effect is less than 25%. |
| | | Moderate | Likelihood of residual effect is between 25% and 75%. |
| | | High | Likelihood of residual effect is greater than 75%. |

Residual Effect #1: Suspended sediment generation during Tunnel removal

Activities associated with Tunnel decommissioning, including removal of Tunnel segments and overlying sediment, will be undertaken under active flow conditions, which could limit the effective use of isolation or sediment control structures such as silt curtains in the area immediately down river from the works. Bed sediments that are re-suspended during Tunnel removal, therefore, could add incrementally to suspended sediment loads in the river. An overview of the criteria ratings for this residual effect is provided in **Table 4.1-3**.

Table 4.1-3 Criteria Ratings: Suspended Sediment Generation during Tunnel Removal.

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|---|
| Direction | Adverse | Suspended sediment concentrations in the river will be higher than background levels. |
| Magnitude | Low | Change will be within the range of natural variability and is not expected to adversely affect viability of receptor VCs. |
| Extent | Local | Spatial extent is expected to be restricted to the LAA. |
| Duration | Transient term | Effect will occur only during Tunnel removal. |
| Frequency | Rare | Effect will occur only in association with Tunnel removal. |
| Reversibility | Reversible | Suspended sediment concentrations are expected to return to baseline conditions following removal of each Tunnel segment. |
| Likelihood | High | The likelihood of increased suspended sediment during Tunnel removal is greater than 75%. |

Removal of the Tunnel and overlying material from the river bed will generate suspended sediment. Increased suspended sediment concentrations are considered an adverse effect since it has the potential to cause fish to avoid the area, or in severe cases, result in injury to fish. The magnitude of the effect will depend on the ambient suspended sediment concentrations at the time of removal, river discharge, tidal amplitude, and details of Tunnel removal methods. The study has assumed Tunnel removal will commence in mid-August, after freshet flows have receded, and continue into the winter low flow period (December). Suspended sediment concentrations in the low-flow period are typically low, so increases beyond background concentrations are considered likely.

The magnitude of the suspended sediment effect is considered low. The estimated volume of suspended sediment that could be generated by the Tunnel removal was compared to the typical ambient volumes of suspended sediment transported during the anticipated Tunnel removal period. Each Tunnel segment is overlain by approximately 28,000 m³ of sediment or sand fill material (**Figure 3-2**). Assuming this material has the same size gradation as the bed material in the lower Fraser River, approximately 10% (2,800 m³) of the overlying material would be smaller than 0.177 mm in diameter, and could therefore remain suspended in the water column (NHC 2002b). Assuming that removal of one Tunnel segment takes two weeks, the natural or ambient volume of suspended sediment transported through the study area during removal of one segment ranges from a maximum of 3x10⁵ m³ in August to a minimum of 3x10⁴ m³ in December. These estimates are based on analyses of seasonal flows and measured suspended sediment concentrations in the lower Fraser River (Milliman 1980, Kostaschuk, Luternauer, et al. 1989, Attard and Venditti 2014). Based on the above estimates, the increase in suspended sediment volume due to the Tunnel removal ranges from one per cent to nine per cent over ambient volumes. Considering the wide variation in suspended sediment concentrations in the Fraser River South Arm on a seasonal and annual timescale, the magnitude of the effect can be characterized as low.

Spatial extend of the suspended sediment increases is expected to be limited to within the LAA. After removal of each Tunnel segment, suspended sediment concentrations are expected to return to normal, so the effect is reversible. The generation of suspended sediment will occur only during Tunnel removal, and will return to normal after removal, so the frequency of the effect is rare and the duration is transient.

Depositional changes resulting from suspended sediment generation are expected to be minimal. Suspended fine sediments generated during Tunnel removal would be transported to the Strait of Georgia before deposition could occur in the main channel. Since the incremental volume of suspended sediment generated during Tunnel removal is expected to be small in comparison with the ambient load, and the depositional area at Sand Heads is large, no noticeable changes to deposition in the Strait of Georgia are expected. It is possible that some of the suspended sediment generated from removal of the southern Tunnel segments could deposit in low velocity environments such as Ladner slough or the margins of Ladner Reach, Canoe Passage or other side channels. If such deposition occurs, it is expected to be minor.

Residual Effect #2: Temporary bed lowering between the Tunnel alignment and the Lulu Island-Delta watermain

Removal of the Tunnel segments will leave a trench in the river bottom, and sediments transported from upstream will tend to be trapped in the trench as it fills and migrates downstream. During this time there will be less sediment available to replenish the river bed downstream of the Tunnel alignment. Model results suggest the river bed between the Tunnel and Lulu-Delta watermain will be temporarily lowered by 1 to 2 m compared with baseline conditions. Bed lowering is not expected to propagate upstream of the Tunnel or downstream of the watermain, and levels between the Tunnel and watermain are expected to return to normal after the trench has filled in (within one to two freshets). An overview of the criteria ratings for this residual effect is presented in **Table 4.1-4**.

Table 4.1-4 Criteria Ratings: Temporary Bed Lowering between the Tunnel Alignment and the Lulu Island-Delta Watermain

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|---|
| Direction | Adverse | Bed lowering could affect Metro Vancouver’s Lulu-Delta watermain. |
| Magnitude | Moderate | Change will be within the range of natural variability but may have a moderate effect on in-river infrastructure. |
| Extent | Local | Spatial extent is expected to be restricted to within 600 m downstream of the Tunnel alignment. |
| Duration | Short term | Effect expected to persist only until one or two freshets following Tunnel removal. |
| Frequency | Continuous | Effect will occur continuously during Tunnel removal and for the following 1-2 years. |
| Reversibility | Reversible | River bed levels between the Tunnel and Lulu-Delta watermain are expected to return to normal after the trench has filled in. |
| Likelihood | High | The likelihood of lower river bed levels between the Tunnel and Lulu-Delta watermain is greater than 75%. |

The lower bed levels are not expected to negatively impact fish habitat or navigability, but has the potential to dislodge rock at the edges of the existing scour protection apron at Lulu Island-Delta watermain, about 600 m downstream of the Tunnel. These types of rock aprons are designed to fall, or launch, into developing scour holes to prevent or delay further scour. However once this has occurred their ability to protect against further scour is compromised. The 1-2 m of bed lowering would not expose the watermain directly, but could diminish the future effectiveness of the scour protection.

The predicted 1-2 m of bed lowering is within the range of natural variability on the Fraser River. Seasonal changes and the passage of dunes on the riverbed regularly induce changes in elevation greater than 2 m; however given the potential for this bed lowering to affect the watermain, the magnitude of the effect is considered moderate.

4.1.6 Cumulative Effects

The combination of Project-related changes and changes from other certain and reasonably foreseeable projects and activities, as listed in **Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**, comprise the total cumulative changes in river hydraulics and river morphology. The only other project or activity that has the potential to have effects that could interact with those of the Project is the routine maintenance dredging of the Fraser River South Arm by the Vancouver Fraser Port Authority (VFPA), which overlaps spatially with the Project. It is anticipated that Tunnel decommissioning will be scheduled in consultation with VFPA such that there is no temporal overlap of potential effects of the two activities on river hydraulics and river morphology, and no construction-related cumulative effects are expected.

4.1.7 Follow-up Strategy

Frequent monitoring of riverbed within 100 m upstream and downstream of the Lulu Island-Delta watermain is proposed during and after Tunnel removal to ensure resultant temporary change in river bed profile does not impact the watermain. Regular monitoring at appropriate intervals will begin during Tunnel removal. Monitoring frequency may be revised following Tunnel removal, based on a review and evaluation of monitoring results by a qualified registered professional (QRP). If a lowering of the edges of the water main's scour protection apron is noticed, the apron will be upgraded under the direction of the QRP.

4.2 Sediment and Water Quality Assessment Highlights:

- The new bridge will have a clear-span, which reduces potential Project-related effects on sediment and water quality in the Fraser River South Arm.
- Minor, temporary increases in turbidity in the Fraser River South Arm, as compared with baseline conditions, are expected during Tunnel decommissioning.
- No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.
- Applying mitigation, including timing windows for undertaking in-stream works, will avoid or minimize potential effects of Project-related changes in water quality on receptor components, including fish and fish habitat.
- Elements of the Project design, including the use of biofiltration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99.
- No Project-related post-construction residual effects or cumulative effects on sediment and water quality are expected.

4.2 Sediment and Water Quality

This section describes the existing conditions of sediment and water quality in waterbodies that could potentially be affected by the Project, and anticipated changes that may result from Project components and activities. Sediment and water quality comprises one of the ‘steps’ along the pathway of effects of the Project, with fish and fish habitat, marine mammals, vegetation, and at-risk amphibians being the ultimate receptors of Project-related effects. Sediment and water quality has therefore been studied as an intermediate component (IC), and information on predicted Project-related changes in sediment and water quality was used to support the assessment of Project-related effects on the following valued components (VCs): fish and fish habitat (**Section 4.4 Fish and Fish Habitat**), at-risk amphibians (**Section 4.5 At-risk Amphibians**), marine mammals (**Section 4.6 Marine Mammals**), and vegetation (**Section 4.7 Vegetation**).

This section focuses on the Fraser River South Arm, Deas Slough, and Green Slough, which are the major waterbodies that could be affected by the Project. Potential changes in sediment and water quality as a result of upland ditch construction and relocation to accommodate widening of Highway 99 are discussed in the assessment of Project-related effects on fish and fish habitat (**Section 4.4 Fish and Fish Habitat**).

The Project will include stormwater collection and treatment components (e.g. biofiltration ponds) to capture, detain, and treat stormwater runoff prior to discharging into water courses. These stormwater management components, and implementation of appropriate construction environmental management plans as described in **Section 12.0 Management Plans**, are

expected to avoid any potential effect due to stormwater runoff from the upgraded highway, including the new bridge. Proposed Project-related improvement in stormwater collection and management along the Highway 99 corridor is anticipated to result in an improvement in the quality of stormwater entering adjacent watercourses. As such, an assessment of Project-related change in water or sediment quality in upland ditches and streams was not undertaken as part of this assessment.

Standard best management practices such as development and implementation of a Fish and Fish Habitat Management Plan and compliance with the B.C. *Water Act*, are expected to prevent potential changes to sediment and water quality in upland ditches during Project construction and operation. These are discussed in more detail in **Section 4.4 Fish and Fish Habitat**, and are not considered further in this section.

4.2.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on sediment and water quality in terms of Project setting and defines the spatial and temporal assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

4.2.1.1 Assessment Context

The Project alignment crosses the Fraser River South Arm, Deas Slough, and Green Slough, which support an important ecosystem. A clear span is proposed over the Fraser River and Deas Slough to minimize impacts to this ecosystem; however construction-related activities—specifically, installation of bridge foundations along the edge of Deas Slough, Tunnel removal, and decommissioning of the Deas Slough Bridge—have the potential to temporarily influence the quality of water and sediment in these water bodies through the introduction of turbidity and resuspension of bed sediments. Predicting the anticipated nature and magnitude of such changes is important for assessing Project-related effects on receptor VCs (fish and fish habitat, marine mammals, vegetation, and at-risk amphibians). Sediment and water quality has therefore been selected as an intermediate component in the assessment of Project-related effects on receptor VCs. Input received through consultation with government agencies, Aboriginal Groups, and the general public also informed the decision to undertake an assessment of sediment and water quality. During pre-Application consultation on the Project, water quality in the Fraser River was identified as an area of specific interest by Aboriginal Groups.

Additional information on the selection of VCs, and the link between water and sediment quality and receptor VCs is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**.

4.2.1.2 Methodology

Changes in riverbed sediment characteristics that have the potential to affect receptor VCs include changes in sediment composition and organic carbon content, and changes in sediment quality in terms of contaminant concentrations. Similarly, changes in the water column that have the potential to affect receptor VCs include changes in total suspended solids (TSS) and turbidity levels, or changes in ambient water chemistry. Therefore, Project-related study of water and sediment quality was designed to focus on these aspects.

A literature review, gap analysis, and field program, as outlined in **Table 4.2-1**, were undertaken to establish existing conditions, and sediment fate predictions described in **Section 4.1 River Hydraulics and River Morphology** were used to identify potential Project-related effects on water quality and sediment quality in the Fraser River South Arm, Deas Slough, and Green Slough.

Table 4.2-1 Sediment and Water Quality Studies to Support the Assessment

| Study Name | Study Description |
|------------------------------------|--|
| Literature Review/ Gap Analysis | Information from historic studies and data collected during previous field work in 2013 were reviewed to describe existing conditions of sediment and water quality and to identify information gaps. |
| Field Study | Project-specific sampling and analyses were conducted in September 2014 to describe sediment and water quality conditions in Fraser River South Arm in the vicinity of the Tunnel, and Deas Slough and Green Slough. |

4.2.1.3 Assessment Boundaries

The assessment boundaries for sediment and water quality are defined below.

Spatial Boundaries

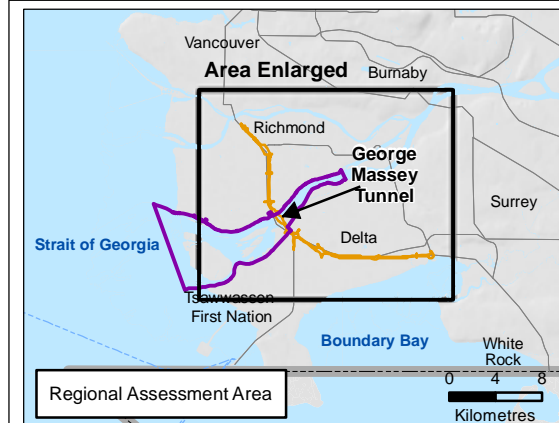

Changes in sediment and water quality in the Fraser River South Arm due to Project activities are expected to be most prominent within the Project alignment, immediately adjacent to instream or near-shore activities such as installation of bridge foundations along the edge of Deas Slough, Tunnel removal, and decommissioning of the Deas Slough Bridge. However, due to tidal influences and river hydrology, there could be Project-related effects to water quality, suspended sediment characteristics, or riverbed sediment characteristics some distance

downstream and upstream of the Tunnel. A local assessment area as defined in **Table 4.2-2** and shown on **Figure 4.2-1** was selected, taking these factors into account. Spatial extent of the LAA was refined to include Ladner Reach and South Arm Marshes based on feedback received from Aboriginal Groups and regulatory agencies during pre-Application consultation.

A regional assessment area (RAA), which comprises the river reach extending approximately seven kilometres upstream from the Tunnel, and downstream from the Tunnel to the river mouth (**Figure 4.2-1**), has been defined to provide regional context.

Table 4.2-2 Spatial Boundaries for Sediment and Water Quality Assessment

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|--|
| Local Assessment Area (LAA) | Fraser River South Arm extending approximately seven kilometres downstream from the Tunnel (including Ladner Reach and South Arm Marshes) and 1.5 km upstream of the Tunnel; Deas Slough and Green Slough; and upland water courses within the Project alignment plus 30 m buffer. |
| Regional Assessment Area (RAA) | Fraser River South Arm extending seven kilometres upstream from the Tunnel, and downstream from the Tunnel to the river mouth (past Westham Island). |

GEORGE MASSEY TUNNEL REPLACEMENT PROJECT

SEDIMENT AND WATER QUALITY LOCAL AND REGIONAL ASSESSMENT AREAS

Figure 4.2-1

13/05/2016

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects were established based on the potential for each phase of the Project to interact with and have an effect on water and sediment quality. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, both the construction and operational phases of the Project include components and activities that could interact with and affect the quality of water and sediments in the Fraser River South Arm, and Deas and Green Sloughs; therefore, the following temporal boundaries were defined for sediment and water quality assessment:

- Existing conditions
- Project construction, which includes Tunnel decommissioning
- Project operation, including maintenance

Temporal characteristics (timing) of the Project construction phase (including decommissioning of temporary construction-related facilities and the Tunnel), and operation phases are defined in **Section 1.1.3 Project Phases and Schedule**. Specific temporal considerations for the assessment of water and sediment quality are discussed in the context of Project interactions and potential effects in **Section 4.2.3**.

Administrative Boundaries

No political, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects on water and sediment quality have been identified; therefore no administrative boundaries are defined.

Technical Boundaries

The technical boundaries for water and sediment quality assessment are associated primarily with the amount of location-specific data on sediment and water quality under existing conditions, including variations across space, depth in the water column or riverbed, and over time. The processes known to influence sediment and water quality within the LAA and RAA are well-understood, and the observations and interpretations that underpin this assessment are entirely consistent with expectations based on the greater theoretical understanding.

4.2.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data and describes the existing conditions of sediment and water quality within the assessment areas. An overview of the regulatory context for management of water and sediment quality as relevant to the Project is also provided.

4.2.2.1 Baseline Data Collection

In early 2014, the Ministry initiated desktop and field studies to support the environmental assessment of the proposed Project. The studies were designed to build on existing information and address known data gaps.

The information on existing sediment and water quality presented here is based on a review of multiple historical documents, previous sample data collected in 2013, and a field sampling program specific to the Project. The interpretation of existing conditions in relation to sediment and water quality is grounded in a contemporary theory regarding the relationships between river hydrology and sediment supply (as discussed in **Section 4.1 River Hydraulics and River Morphology**) and sediment fate, including contaminant hydrogeochemistry.

A Project-specific field program was conducted in September of 2014 to collect sediment and water quality data. While this limited field program does not capture temporal variations that are associated with river discharge stage or dry periods in comparison with extended periods of precipitation, fulsome historic data exists to address this gap. Seasonal variations in riverine conditions and in local runoff are expected to influence the characteristics of finer-grained sediments that are entrained in the river water, as well as the contaminants associated with them. Fine-grained sediments tend to be routinely transported through the Project Area without appreciable deposition (described as washload in **Section 4.1 River Hydraulics and River Morphology**), and therefore, are considered less relevant to an assessment of changes to sediment and water quality in the context of bed sediment re-suspension during Project construction activities. An exception to this is the accumulation of fine-grained sediments in Deas and Green Sloughs.

Literature Review

Background information was reviewed and data that pertain to the following were collected:

- Substances and conditions for which observed concentrations approach or exceed Canadian sediment quality guidelines (SQG) for the protection of aquatic life (CCME 2014a), the water quality guidelines (WQG) for the protection of aquatic life (CCME 2014b), or the B.C. WQGs (B.C. MOE 2006).

- Temporal trends in sediment and water quality parameters in the Fraser River South Arm, specifically within the LAA and RAA, where available.
- Causal relationships between environmental variables and water quality parameters (e.g., relationship between fine-grained sediment and chromium concentrations).

Field Studies

Field studies were undertaken within the LAA (**Figure 4.2-2**), to characterize surficial sediment and assess water quality. Sampling was conducted on September 11 and 12, 2014, during low-flow conditions in the Fraser River.

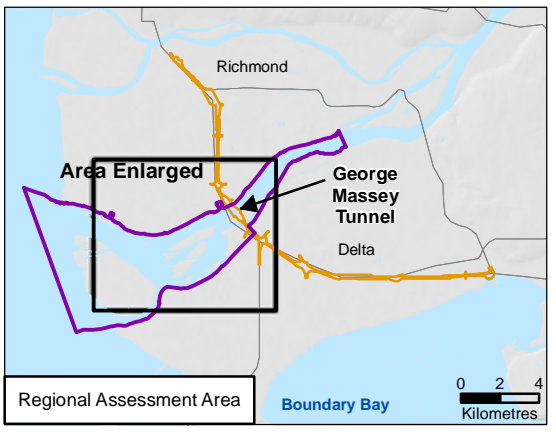

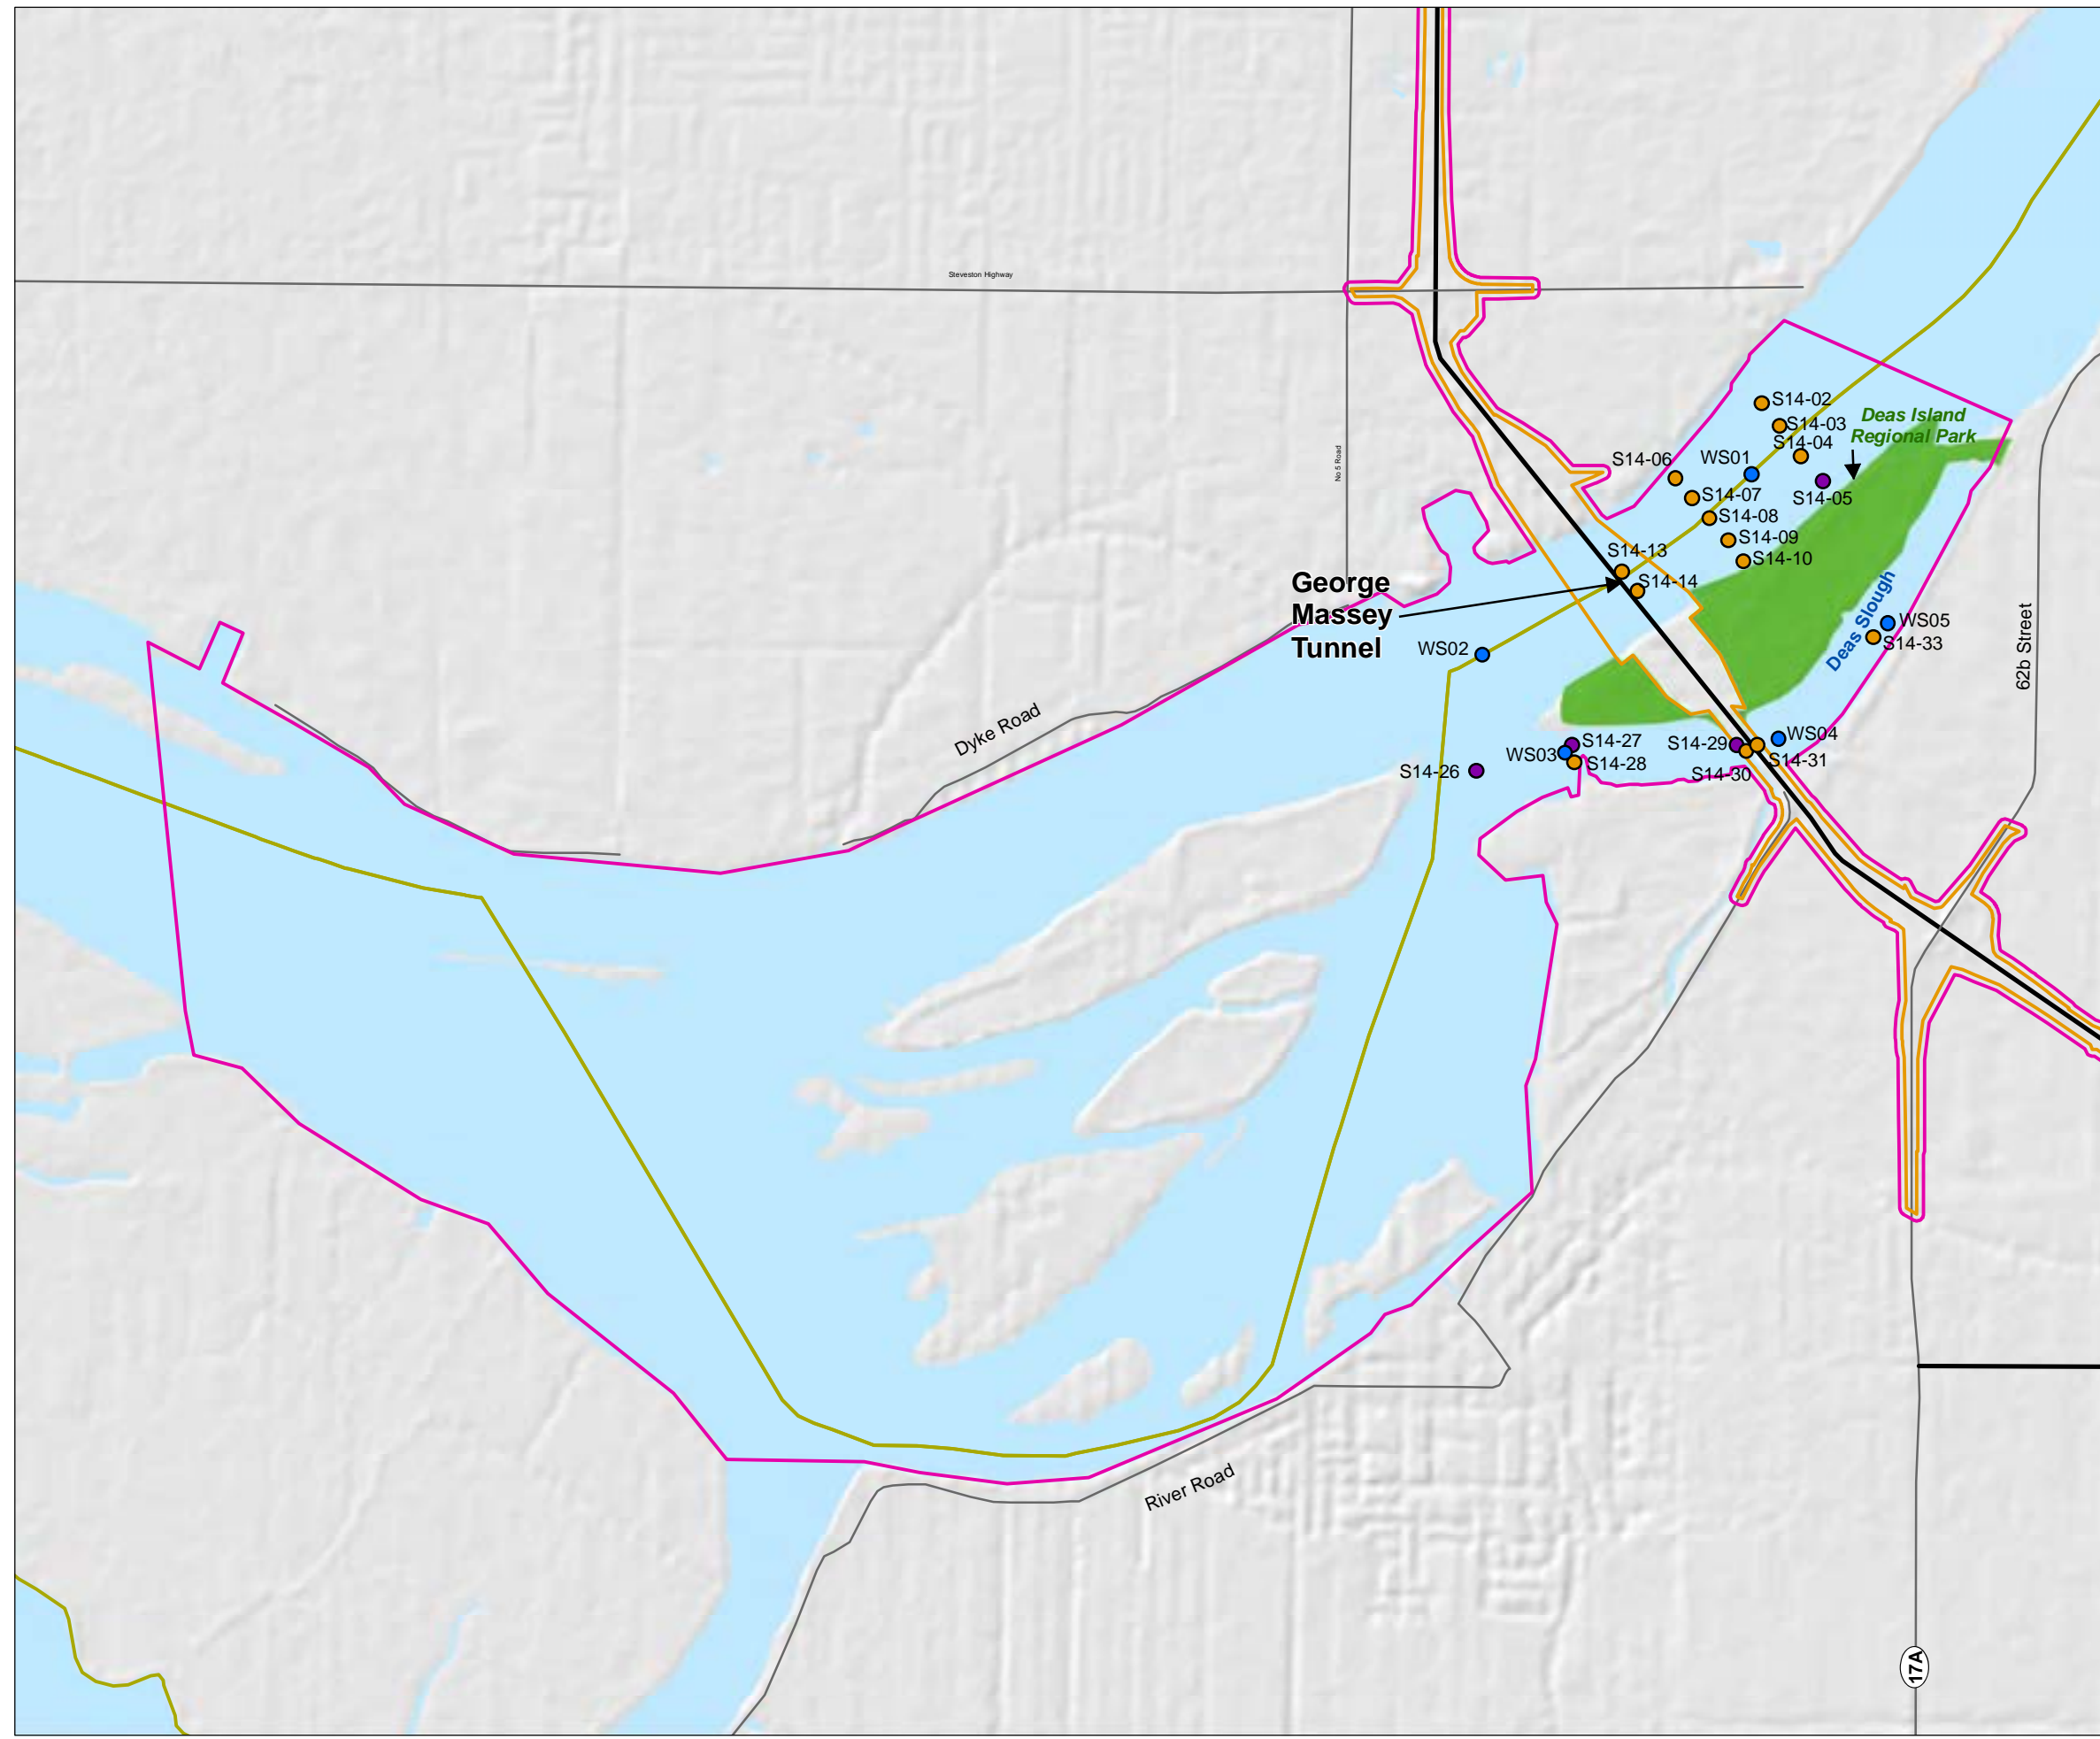

Sediment Characterization

Sediment samples were collected using a combination of surface grabs from the top ~25 to 30 cm of the riverbed using a 0.1 m² stainless steel Van Veen grab and vibracoring to obtain information on vertical distribution of contaminants. The maximum sample depth achievable was approximately 2 m below the riverbed.

Information from historic studies and previous field work were reviewed to describe existing conditions of sediment and water quality. To supplement this existing data, samples were collected at representative locations in the Fraser River near the Tunnel and in Deas Slough. The samples were handled in accordance with the *B.C. Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples* (B.C. MWLAP 2003). Samples were stored in the appropriate non-contaminating containers provided by a commercial analytical laboratory (ALS Environmental Services). Samples were analyzed for particle size distribution, total organic carbon, trace elements, extractable petroleum hydrocarbons (EPH), polycyclic aromatic hydrocarbons (PAH), and polychlorinated biphenyls (PCB).

Water Quality Sampling and Analyses

Water samples were collected at five locations within the LAA (**Figure 4.2-2**): one mid-channel reference site upstream of the Tunnel, two mid-channel sites downstream of the Tunnel, and two sites in Deas Slough. Water samples were collected and analyzed in accordance with the *B.C. Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples* (B.C. MWLAP 2003).

4.2.2.2 Regulatory Context

Federal

In the context of sediment and water quality, the federal *Fisheries Act*, R.S.C. 1985, c. F-14 is relevant to the Project. Section 35 (1) of the *Fisheries Act* regulates any work, undertaking, or activity that results in serious harm to fish (defined as the death of fish or any permanent alteration or destruction of fish habitat) that are part of or support a commercial, recreational or Aboriginal fishery. Section 36 (3) regulates the deposition of a deleterious substance of any type in water frequented by fish. A deleterious substance may include excess concentrations of suspended sediment.

The Canadian Environmental Quality Guidelines (CEQG) of the Canadian Council of Ministers of the Environment (CCME) define numerical concentrations recommended as levels that should result in negligible risk to biota and fish habitat function. Specific CCME CEQG that apply to the Project include sediment quality guidelines for the protection of aquatic life (CCME 2014a) and the CCME water quality guidelines for the protection of aquatic life (CCME 2014b).

Provincial

The B.C. Ministry of Environment develops ambient WQGs to promote healthy ecosystems and protect human health. Water quality guidelines are science-based levels of physical, biological, and chemical parameters for the protection of water uses such as aquatic life, wildlife, agriculture, drinking water, and recreation. Approved WQGs are policy statements and applied generically province wide, providing the basis for water quality assessments and informing decision-making in the natural resource sector.

Section 9 of the B.C. *Water Act* R.S.B.C. 1996, c. 483 regulates changes in and about a stream. The Act defines “changes in and about a stream” as:

- a) any modification to the nature of a stream including the land, vegetation, natural environment or flow of water within a stream
- b) any activity or construction within the stream channel that has or may have an impact on a stream.

4.2.2.3 Existing Conditions

Sediment Texture

Sediments within the Fraser River South Arm comprise grain sizes dominated by sand ranging in diameter from 0.25 to 0.5 mm (Swain and Walton 1991, McLaren and Tuominen 1999, Phippen 2001). In contrast, sediments in and near Deas Slough shift to a more diverse and smaller particle size (McLaren and Tuominen 1999, Phippen 2001). In general, sloughs, side-channel areas, or nearshore eddies of the Fraser River South Arm tend to accumulate finer-textured clayey and silty sediments, while the higher current areas in the main river channel (and in the designated navigational channel) are characterized by sandy sediments with very limited fines. Grain size distribution from sediment core samples extracted from Deas Slough and the Fraser River South Arm during field studies conducted for the Project is illustrated in **Appendix A, Figure 1**. Grain size composition is consistent across all depths (**Appendix A, Figures 2 and 3**).

Sediment Quality

Bed sediments in some areas of the Fraser River South Arm contain trace elements, PAHs, and other organic contaminants at levels that may exceed Canadian SQGs. Historically, samples collected in the South Arm have routinely exceeded Canadian SQGs for arsenic, chromium, and copper (Swain and Walton 1991, 1993, Brewer et al. 1998). These trace elements occur at higher concentrations in the finer-textured (silt and clay) fractions of bed sediments (**Appendix A, Figure 4**). Fine-grained (<0.063 mm), organic-rich sediments, such as those occurring in Deas Slough and Green Slough, preferentially adsorb metals due to higher adsorption capacity and higher surface area compared with coarse-grained sediments (Ackermann 1980, Salomons and Förstner 1984, Horowitz et al. 1989, Tyson 1995). Arsenic, chromium, and copper concentrations that exceed Canadian interim SQGs were found in sediment samples collected from Deas Slough as part of the field studies completed for the Project in 2014 (**Appendix A, Figure 5**). There was no apparent variation in trace element concentrations within the sampling depth of two metres (**Appendix A, Figure 6**).

Sediment within the LAA that currently comprises the riverbed material directly adjacent to the Tunnel (except near the river banks) can be described as coarse-grained, with very low concentrations of chemical constituents. Annual dredging takes place in the Fraser River South Arm with associated disturbance to sediments and water in the LAA and RAA.

Water Quality

Data collected during Project-related field studies in 2014 indicate that water in the Fraser River South Arm is of good quality, with parameters such as pH, temperature, dissolved oxygen, and electrical conductivity falling within CCME WQGs for the protection of aquatic life (CCME 2014b).

Given that the river naturally carries large loads of suspended sediments, high turbidity/TSS concentrations are often observed during surface water sampling in the Fraser River South Arm. Turbidity levels can range widely, from 1.8 to 87.8 NTUs (nephelometric turbidity units), which reflects the influence of tides and freshwater outflow on silt loads and levels of sediment re-suspension. At the time of sampling for the Project (September 2014), TSS concentrations ranged between 8.8 mg/L and 28.4 mg/L, which reflects wind and tidal interaction rather than turbid freshwater outflow.

Instances of elevated concentrations of aluminum, chromium, and copper, which correlated with TSS concentrations at the same locations, were noted. Increased total levels of naturally occurring trace elements are typical in waters with increased TSS levels, with trace elements being more mobile and more bioavailable.

PAHs, EPH, oil, or grease were detected in any water sample. Concentrations of total and dissolved aluminum, chromium, and copper from grab samples collected during the 2014 field studies conducted for the Project are shown in **Appendix A, Figure 7**.

4.2.3 Potential Effects

This section provides a summary of potential changes to sediment and water quality related to the construction and operation of the Project, and describes the methodology used to assess potential project-related effects. An overview of potential interactions of Project components and activities with water and sediment within Fraser River South Arm, Deas Slough, and Green Slough is presented, and potential effects of such interactions on water and sediment quality are discussed. Information on mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 4.2.4**. Potential residual effects (i.e., effects remaining following the implementation of mitigation measures) are described in **Section 4.2.5**. A discussion of the potential for cumulative effects on water and sediment quality is presented in **Section 4.2.6**.

4.2.3.1 Project Interactions

An overview of potential interactions between Project activities and water and sediment during the construction and operation of Project components is provided in **Appendix B**. A preliminary evaluation of the potential effects of Project interactions on sediment and water quality, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Construction: Potential interactions of Project-related construction activities with water and sediment include the following:

- Disturbance of river bed material during removal of sediment, rock apron, and concrete mattress in preparation for Tunnel removal, removal of Tunnel segments, installation of bridge piers along the edge of Deas Slough, and removal of the Deas Slough Bridge.
- Movement of construction vessels and equipment along the Fraser River during installation of bridge components, transportation of Tunnel elements for offsite disposal, and operating support vessels for that activity.

Operation: Potential interactions of Project-related operation activities with sediment and water include the following:

- Maintenance of stormwater management ponds and drainage facilities during operations.

4.2.3.2 Potential Effects

Construction

Localized disturbance of surficial sediments is expected to occur during installation of temporary barging facilities, and removal of Tunnel segments.

Potential effects of activities associated with Tunnel removal on sediment generation, or re-suspension, are discussed in **Section 4.1 River Hydraulics and River Morphology**. The impact of sediment generation will depend on ambient suspended sediment concentrations at the time of removal. It is assumed that Tunnel removal will commence in mid-summer, after freshet flows have receded, and extend into the winter low-flow period. Suspended sediment volume is predicted to temporarily increase between one per cent and nine per cent over ambient levels during the course of disturbance. The impact of this increase is considered low, given the natural variability of suspended sediment seasonally and annually in the river main channel. Fine sediments are anticipated to remain in suspension and be carried downstream to the Strait of Georgia (for details see **Section 4.1 River Hydraulics and River Morphology**).

During Tunnel decommissioning, water velocity is expected to decrease over the Tunnel trench as segments are removed in sequence, resulting in temporary, localized re-distribution of bed sediments through scouring and deposition, with entrained sediment deposited immediately downstream. Potential changes to sediment and water quality are therefore expected to be temporary and small in scale compared with overall bed material transport, as described in **Section 4.1 River Hydraulics and River Morphology**.

Project-related construction activities along the edge of Deas Slough and Green Slough that have the potential to induce turbidity include runoff, ground improvements, realignment of Green Slough to its historic location, and pile driving and construction of piers for the new bridge south approach. Temporary, localized disturbance of surficial sediments is also expected to occur during geotechnical investigations along the edges of Deas Slough and Green Slough and demolition of the Deas Slough Bridge.

Concentrations of metals (arsenic, chromium, copper) greater than those found in the sandy sediments of the Fraser River South Arm in the vicinity of the Project have been documented in the fine-grained sediments of Deas Slough historically, and were noted during field sampling conducted in September 2014 for the Project (see **Section 4.2.2**). This aligns with findings of historical reports, which show that fine-grained sediments preferentially adsorb organic particles and metals due to higher adsorption capacity and higher surface area compared with coarse-grained sediments. There is potential for temporary re-suspension of these materials into the water column in Deas Slough during Project construction.

The main channel of the Fraser River South Arm consists primarily of coarser-grained sediment, with metal concentrations not exceeding Canadian SQGs. Therefore no potential change in water quality due to re-suspended sediment contaminants is expected during construction-related activities in the Fraser River South Arm, including Tunnel decommissioning.

Accidental spills of toxic or hazardous materials (e.g., hydrocarbon fuels, lubricants, concrete), or potential failure of sediment containment measures could affect sediment and water quality during Project construction. The magnitude of such changes would vary as a function of the proximity of the disturbed areas to the river, its tributaries or stormwater collection points, or the extent and slope of exposed and erodible soils. Potential changes in surface water quality resulting from accidents or malfunctions during Project construction are assessed in **Section 8.0 Accidents and Malfunctions**.

Operation

Project-related widening of the highway and installation of the new bridge will result in an increase in impervious surface area and consequent increase in the rate of stormwater runoff that may enter the river and sloughs. An increase in peak flow rates has the potential to affect water quality in the receiving aquatic environment due to increased concentrations of nutrients, organics, metals, chlorides, bacteria, and hydrocarbons (Erickson et al. 2013), especially during first flush and peak storm events.

4.2.4 Mitigation Measures

This section describes the mitigation measures that will be implemented to avoid or reduce potential Project-related effects on sediment and water quality as discussed in **Section 4.2.3.2**.

4.2.4.1 Mitigation Selection Approach

Selection of mitigation measures has been informed by a review of standard industry and best management practices; consideration of mitigation measures and follow up programs undertaken for past developments by the Ministry; input from regulators, public, and Aboriginal Groups; and internal evaluation of technical and economic feasibility. Consideration was given to the following standards and guidelines:

- *2012 Standard Specifications for Highway Construction* (B.C. MOTI 2012)
- *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010)
- *Measures to Avoid Causing Harm to Fish and Fish Habitat* (DFO 2013)
- *Land Development Guidelines for the Protection of Aquatic Habitat* (Chilibeck et al. 1993)
- *Environmental Management Strategy for Dredging in the Fraser River Estuary* (FREMP 2006)
- *Dredge Management Guidelines* (FREMP 2005)
- *Standards and Best Practices for Instream Works* (B.C. MWLAP 2004)
- *Develop with Care 2014: Environmental Guidelines for Urban and Rural Land Development in British Columbia* (B.C. MOE 2014)

Proposed mitigation considerations were informed by feedback received from Aboriginal Groups and stakeholders during pre-Application consultation, including interest expressed in use of bioengineering techniques on land (e.g. biofiltration areas) to prevent direct runoff into the Fraser River.

A hierarchical approach, based on avoidance of potential effects first followed by minimization or reduction of unavoidable effects, was used in identifying strategies to mitigate potential Project-related effects on water and sediment quality.

Measures to avoid potential effects have been/will be incorporated into project considerations such as site and route selection, scheduling, design, construction, and operation procedures and practices. Where potential effects cannot be avoided through project considerations, standard mitigation measures, Best Management Practices (BMPs), and construction and operation environmental management plans (EMPs) will be implemented to minimize potential Project-related effects or reduce them to acceptable levels. These measures are described in general terms below.

4.2.4.2 Avoidance

The bridge design will incorporate a stormwater collection and distribution system that conveys stormwater runoff to appropriate upland infrastructure for proper treatment (e.g., stormwater detentions ponds or biofiltration swales) before discharging to the Fraser River or adjacent streams, thereby avoiding potential impacts on the water and sediment quality. These enhanced stormwater management approaches are expected to result in an improvement in water and sediment quality in the Fraser River when compared to existing conditions

4.2.4.3 Minimization

Project Design

The new bridge will have a clear span over the Fraser River and over Deas Slough to minimize construction-related effects including effects on water quality and disturbance to the river bed.

Best Management Practices and Environmental Management

Specific environmental protection measures that will be implemented during Project construction and operation to prevent or minimize environmental effects will be identified in a CEMP, and subsequently in an Operation Environmental Management Plan (OEMP), as described in **Section 12.0 Management Plans**.

Control of Suspended Sediment during Tunnel Decommissioning

Construction methods that minimize levels of Project-induced turbidity in the Fraser River main channel will be employed where feasible and appropriate. To the extent technically feasible and viable, removal of fill materials adjacent to the Tunnel will be conducted in a manner that minimizes re-suspension of sediments—using hydraulic (hopper or cutter) suction for example.

Removed material is expected to be transported off-site using spoil barge(s) equipped with a sediment containment system (e.g., filter cloth, concrete lock blocks, straw bales).

Control of Suspended Sediment during Project Construction in and adjacent to Deas and Green Sloughs

Sediment control measures (e.g., turbidity curtains) will be used to control the dispersion of re-suspended sediments in Deas Slough generated by physical bed disturbance during ground improvements, pier construction activities on the edge of Deas Slough, and demolition of existing infrastructure. Measures to control suspended sediment during Project construction in Deas and Green Sloughs will be described in the Erosion and Sediment Control Plan within the CEMP. Erosion prevention and sediment control measures that will be implemented during construction may include, but be limited to:

- Development of temporary drainage systems to receive, filter, and direct stormwater and runoff during construction
- Installation of sediment control measures
- Development of sediment settlement ponds, if required
- Re-stabilization of vegetated areas that are cleared or disturbed during construction
- Careful storage of waste material and soil to prevent possible entry into the aquatic environment

Water Quality Monitoring during Construction

To assess the effects of Project-specific construction activities on sediment and water quality, and evaluate the effectiveness of mitigation measures, water quality monitoring will be conducted during Project-related construction activities that have the potential to induce turbidity (e.g., Tunnel removal, construction along the edges of Deas Slough and Green Slough). In general, water quality monitoring will include frequent collection of samples at established monitoring stations in the Fraser River main channel within proximity to the Tunnel crossing, as well as downstream of deployed sediment containment measures in Deas Slough, especially during higher risk construction activities. Water quality data will be evaluated in relation to the CCME (2002) and B.C. (B.C. MOE 2006) water quality guidelines (see **Section 4.2.2.2**).

Measures proposed to avoid or minimize Project-related effects on water and sediment quality as discussed above, including collection and treatment of stormwater runoff prior to discharge into streams, and sediment control during Project construction, were identified based on standard best practices and proven methodologies. Accordingly, there is a high level of confidence in the effectiveness of these measures and their ability to prevent Project-related effects on water and sediment quality.

4.2.5 Residual Effects

As discussed in **Section 4.2.4.2**, the Project has been designed with appropriate stormwater runoff collection and management features that prevent direct road runoff into the Fraser River. These enhanced stormwater management approaches are expected to result in an improvement in water and sediment quality in the Fraser River when compared to existing conditions, and no residual adverse effects on water or sediment quality are expected post construction.

Implementation of best practices and proven sediment and erosion control measures as discussed in **Section 4.2.4.3** are expected to avoid any potential effects on water and sediment quality during Project construction. Undertaking Project-related construction activities in Deas Slough within sediment containment structures or other measures will prevent any potential adverse effects to sediment and water quality in the slough due to re-suspension. The very limited extent of in-water or near-water activities are anticipated to be sufficiently small that introduction of suspended sediments into the larger water course can be avoided effectively through the isolation of works using multiple silt curtains or other sediment control measures. Therefore no residual effects on water and sediment quality related to construction within or adjacent to Deas Slough are expected.

Given the anticipated scale and nature of activities associated with Tunnel decommissioning, it is expected that standard best practices and mitigation measures, including use of equipment and methods that minimize sediment resuspension for removal of Tunnel segments and overlying material, will reduce, but not eliminate sediment resuspension. Sediment resuspension and entrainment in active Fraser River flows during Tunnel removal could, therefore, result in temporary increases in TSS and turbidity levels in the overlying water, especially near the river bed. This potential construction-related residual effect on water and sediment quality is characterized below in terms of the direction, magnitude, extent, duration, frequency, reversibility, and likelihood of the effect. Definitions for ratings applied to residual effects criteria, developed with specific reference to water and sediment quality, are presented in **Table 4.2-3**. A summary of criteria ratings for the potential residual effect is provided in **Table 4.2-4**. Context for the characterization of the residual effect, i.e. sensitivity/resilience of water and sediment quality to potential Project-related effects, based on existing conditions, is also provided.

Table 4.2-3 Criteria Used to Characterize Residual Effects on Sediment and Water Quality

| Criteria | Description | Definition of Rating | |
|-----------|--|----------------------|--|
| Direction | Overall nature of the residual effect | Adverse | Negative effect as a result of the Project. |
| | | Positive | Beneficial effect as a result of the Project. |
| | | Neutral | Neutral effect as a result of the Project. |
| Magnitude | Intensity of the effect relative to natural or baseline conditions | Negligible | No measurable change in water or sediment quality |
| | | Low | A measurable change within the range of natural variability, but not expected to directly impact receptor VCs (e.g. fish, including sensitive life stages or aquatic invertebrates). |
| | | Moderate | A measurable change outside the range of natural variability, but not expected to result in substantive effects on receptor VCs. |
| | | High | A measurable change outside the range of natural variability and potentially harmful to receptor VCs. Such changes could be driven either by measurable water quality changes or the associated changes in sediment characteristics following re-deposition. |
| Extent | Geographic extent / distribution of the residual effect | Site | Effect is restricted to the immediate Project alignment. |
| | | Local | Effect is restricted to the LAA. |
| | | Regional | Effect extends beyond the LAA |

| Criteria | Description | Definition of Rating | |
|---------------|---|----------------------|--|
| Duration | Length of time over which the residual effect is expected to persist | Transient term | Effect occurs once during Project construction. |
| | | Short term | Effect occurs during a limited period of days to weeks during Project construction. |
| | | Moderate term | Effect persists over a period of weeks to months. |
| | | Long term | Effect persists beyond construction phase. OR Change is permanent. |
| Frequency | Nature of the occurrence of the residual effect (e.g., how often the stressor affects the IC) | Rare | Effect occurs once during Project construction or operation. |
| | | Uncommon | Effect occurs intermittently during Project construction or operation. |
| | | Frequent | Effect occurs frequently during Project construction or operation. |
| | | Continuous | Effect occurs continuously during Project construction or operation. |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after the disturbance has ceased (or after a period of time after the disturbance has ceased) | Reversible | Baseline conditions will be naturally restored after disturbance has ceased. |
| | | Irreversible | Baseline conditions will not be naturally restored after disturbance has ceased. |
| | | Change | Effect may fluctuate between positive and adverse for the duration of the disturbance. |
| Likelihood | Likelihood that the residual effect may occur | Low | Likelihood of residual effect is less than 5%. |
| | | Moderate | Likelihood of residual effect is between 5% and 25%. |
| | | High | Likelihood of residual effect is greater than 25%. |

Activities associated with Tunnel decommissioning, including removal of Tunnel segments and overlying material, will be undertaken under active flow conditions, which could limit the effective use of isolation or sediment control structures such as silt curtains in the area immediately down river from the works. Bed sediments that are re-suspended during Tunnel removal, therefore, could add incrementally to suspended sediment loads in the river. **Table 4.2-4** presents a summary of the criteria ratings for this residual effect.

Context: Bed sediments and suspended sediments potentially influenced by the Project comprise a minute fraction of the estimated 12 to 31 million tonnes/year of suspended sediment transported by the Fraser River, and the anticipated scale of disturbance to bed sediments is comparable to that associated with maintenance dredging routinely undertaken in the Fraser River South Arm. In addition, the physical and chemical characteristics of sediment likely to be suspended during Tunnel removal are consistent with sediments transported in the Fraser River in general, without any discernible influence of local contaminant source inputs. Sensitivity of water and sediment quality in the river to temporary changes resulting from activities associated with Tunnel removal is therefore considered to be low.

Table 4.2-4 Criteria Ratings: Change in Water Quality during Tunnel Decommissioning

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|-----------|-----------------|---|
| Direction | Adverse | Tunnel decommissioning has the potential to result in a temporary increase in TSS and turbidity in the Fraser River South Arm. |
| Magnitude | Low | Change will be within the range of natural variability, given the high sediment loads transported by the Fraser River South Arm. It is likely that measurable increases in TSS/turbidity will be evident for short periods of time during Tunnel removal within the immediate vicinity of the works; however, influence of this localized change in water quality on fish would be limited, given avoidance behaviours. The re-suspended sediment will be of similar textural and chemical quality to the downriver sediments therefore, deposition of re-suspended sediments in downriver areas is not expected to measurably alter riverbed habitat quality or characteristics. |
| Extent | Site | Spatial extent will be restricted to the area of disturbance. |
| Duration | Short term | Effect will occur only during specific Tunnel removal activities that will unavoidably re-suspend sediments. It is anticipated that there will be periodic instances of sediment re-suspension over several weeks to several months during sequential removal of each of the four Tunnel sections. |

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|---|
| Frequency | Frequent | Effect will occur only in association with Tunnel removal, which comprises a small portion of the overall construction and post-construction project window. Nonetheless, a number of different types of activities are anticipated during the overall Tunnel removal phase, including excavation of adjacent sediments, and various in-river works. As a result there might be relatively frequent bouts of sediment re-suspension that could affect TSS/turbidity levels in the immediate vicinity of the Tunnel. |
| Reversibility | Reversible | Water quality is expected to return to baseline conditions within a few hours, and generally less than one day, following cessation of activities that could result in re-suspension |
| Likelihood | High | There is provisionally estimated to be a greater than 25% probability that a measurable change in TSS or turbidity in the water immediately above and down river from the Tunnel removal work will occur. |

When examining the characteristics of residual effects of Tunnel removal on water and sediment quality, it is important to appreciate that the characterization criteria as discussed above are applied to sediment and water quality as an intermediate component, and may not be relevant to the receptor VCs such as fish. The likelihood rating defines the likelihood of detecting a change in water quality (based on TSS) at a given point in space and time. The likelihood rating does not describe the associated probability of adverse effects to any VC. Characterization of residual adverse effects of construction-related sediment re-suspension on fish and fish habitat is provided in **Section 4.4 Fish and Fish Habitat**.

4.2.6 Cumulative Effects Assessment

The combination of Project-related changes, and changes from other certain and reasonably foreseeable projects and activities, as listed in **Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**, comprise the total cumulative changes in sediment and water quality. The only other project or activity that has the potential to have effects that could interact with those of the Project is the routine maintenance dredging of the Fraser River South Arm by the Vancouver Fraser Port Authority (VFPA), which overlaps spatially with the Project. It is anticipated that Tunnel decommissioning will be scheduled in consultation with VFPA such that there is no temporal overlap of potential sediment and water quality effects of the two activities, and no construction-related cumulative effects are expected.

4.2.7 Follow-up Strategy

Water quality monitoring will be undertaken during Project-related construction activities that have the potential to induce turbidity (e.g., Tunnel removal, construction within or along the edges of Deas Slough and Green Slough) to assess the influence of such activities on sediment and water quality, and evaluate the effectiveness of mitigation measures.

As no Project-related effects are predicted beyond the construction phase, no post-construction follow-up strategy is proposed.

"N/A" indicates that no Project works and/or activities are applicable to the category

4.3 Underwater Noise Assessment Highlights:

- The Project area is highly developed and existing underwater noise levels in the Fraser River, dominated by noise from vessels transiting the river, are relatively high.
- The proposed bridge will have a clear-span over the Fraser River and Deas Slough, minimizing instream works and the potential for underwater noise effects associated with construction.
- Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources can be mitigated effectively by scheduling such activities during periods of low tide when work can be completed under shallow water conditions or in the dry, thereby minimizing potential effects.
- Applying mitigation, including underwater noise monitoring and management during construction, will minimize the potential for Project-related changes in underwater noise conditions to affect fish or marine mammals.
- No post-construction residual effects or cumulative effects on underwater noise conditions are expected.

4.3 Underwater Noise

This section describes the existing conditions of underwater noise in the Fraser River South Arm, and Deas and Green Sloughs, and anticipated changes that may result from Project-related construction and operational activities. Underwater noise comprises one of the ‘steps’ along the pathway of effects of the Project, with fish and fish habitat and marine mammals being the ultimate receptors of Project-related effects. Underwater noise was therefore assessed as an intermediate component (IC) and information on estimated Project-related changes in underwater noise levels was used to support the assessment of Project-related effects on the following valued components (VCs): fish and fish habitat (**Section 4.4 Fish and Fish Habitat**) and marine mammals (**Section 4.6 Marine Mammals**).

4.3.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on underwater noise in terms of Project setting, and defines the spatial, temporal, administrative and technical assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

4.3.1.1 Assessment Context

The Project includes on-shore installation of stone columns and driven piles, localized instream stone column and pile installation along the edges of Deas Slough to support the piers for the clear span over Deas Slough, restoration of Green Slough to its historic alignment, and removal of the four central segments of the Tunnel. Some of these activities have the potential to generate underwater noise that could affect marine mammals and fish in the Fraser River South Arm and Deas Slough. Therefore, predicting the anticipated change in underwater noise conditions during Project construction will support the assessment of Project-related effects on these valued components (VCs). Additional information on the selection of VCs, and the link between underwater noise and the VCs listed above is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**.

4.3.1.2 Methodology

The assessment of underwater noise followed the general methodology described in **Section 3.0 Assessment Methodology**.

In early 2014, the Ministry initiated field and desktop studies to support planning and environmental assessment of the Project. The studies were designed to build on existing information and address known data gaps.

The objectives of the underwater noise studies were to:

- Measure background (ambient) underwater noise levels in areas that could potentially be affected by the Project to establish a baseline for evaluation of Project activities.
- Estimate areas where Tunnel decommissioning and construction activities might elevate underwater sound levels above the baseline.
- Estimate spatial zones where fish and marine mammals could potentially be affected by underwater noise generated by Project-related construction.

These objectives were addressed through completion of specific studies outlined in **Table 4.3-1**.

Table 4.3-1 Underwater Noise Studies to Support the Assessment

| Study Name | Study Description |
|-----------------|---|
| Field Survey | Existing levels of background (ambient) underwater noise were measured in the Fraser River South Arm and Deas Slough. |
| Modelling Study | Acoustic models were used to predict the noise footprint of Tunnel decommissioning and proposed bridge construction activities. |

4.3.1.3 Assessment Boundaries

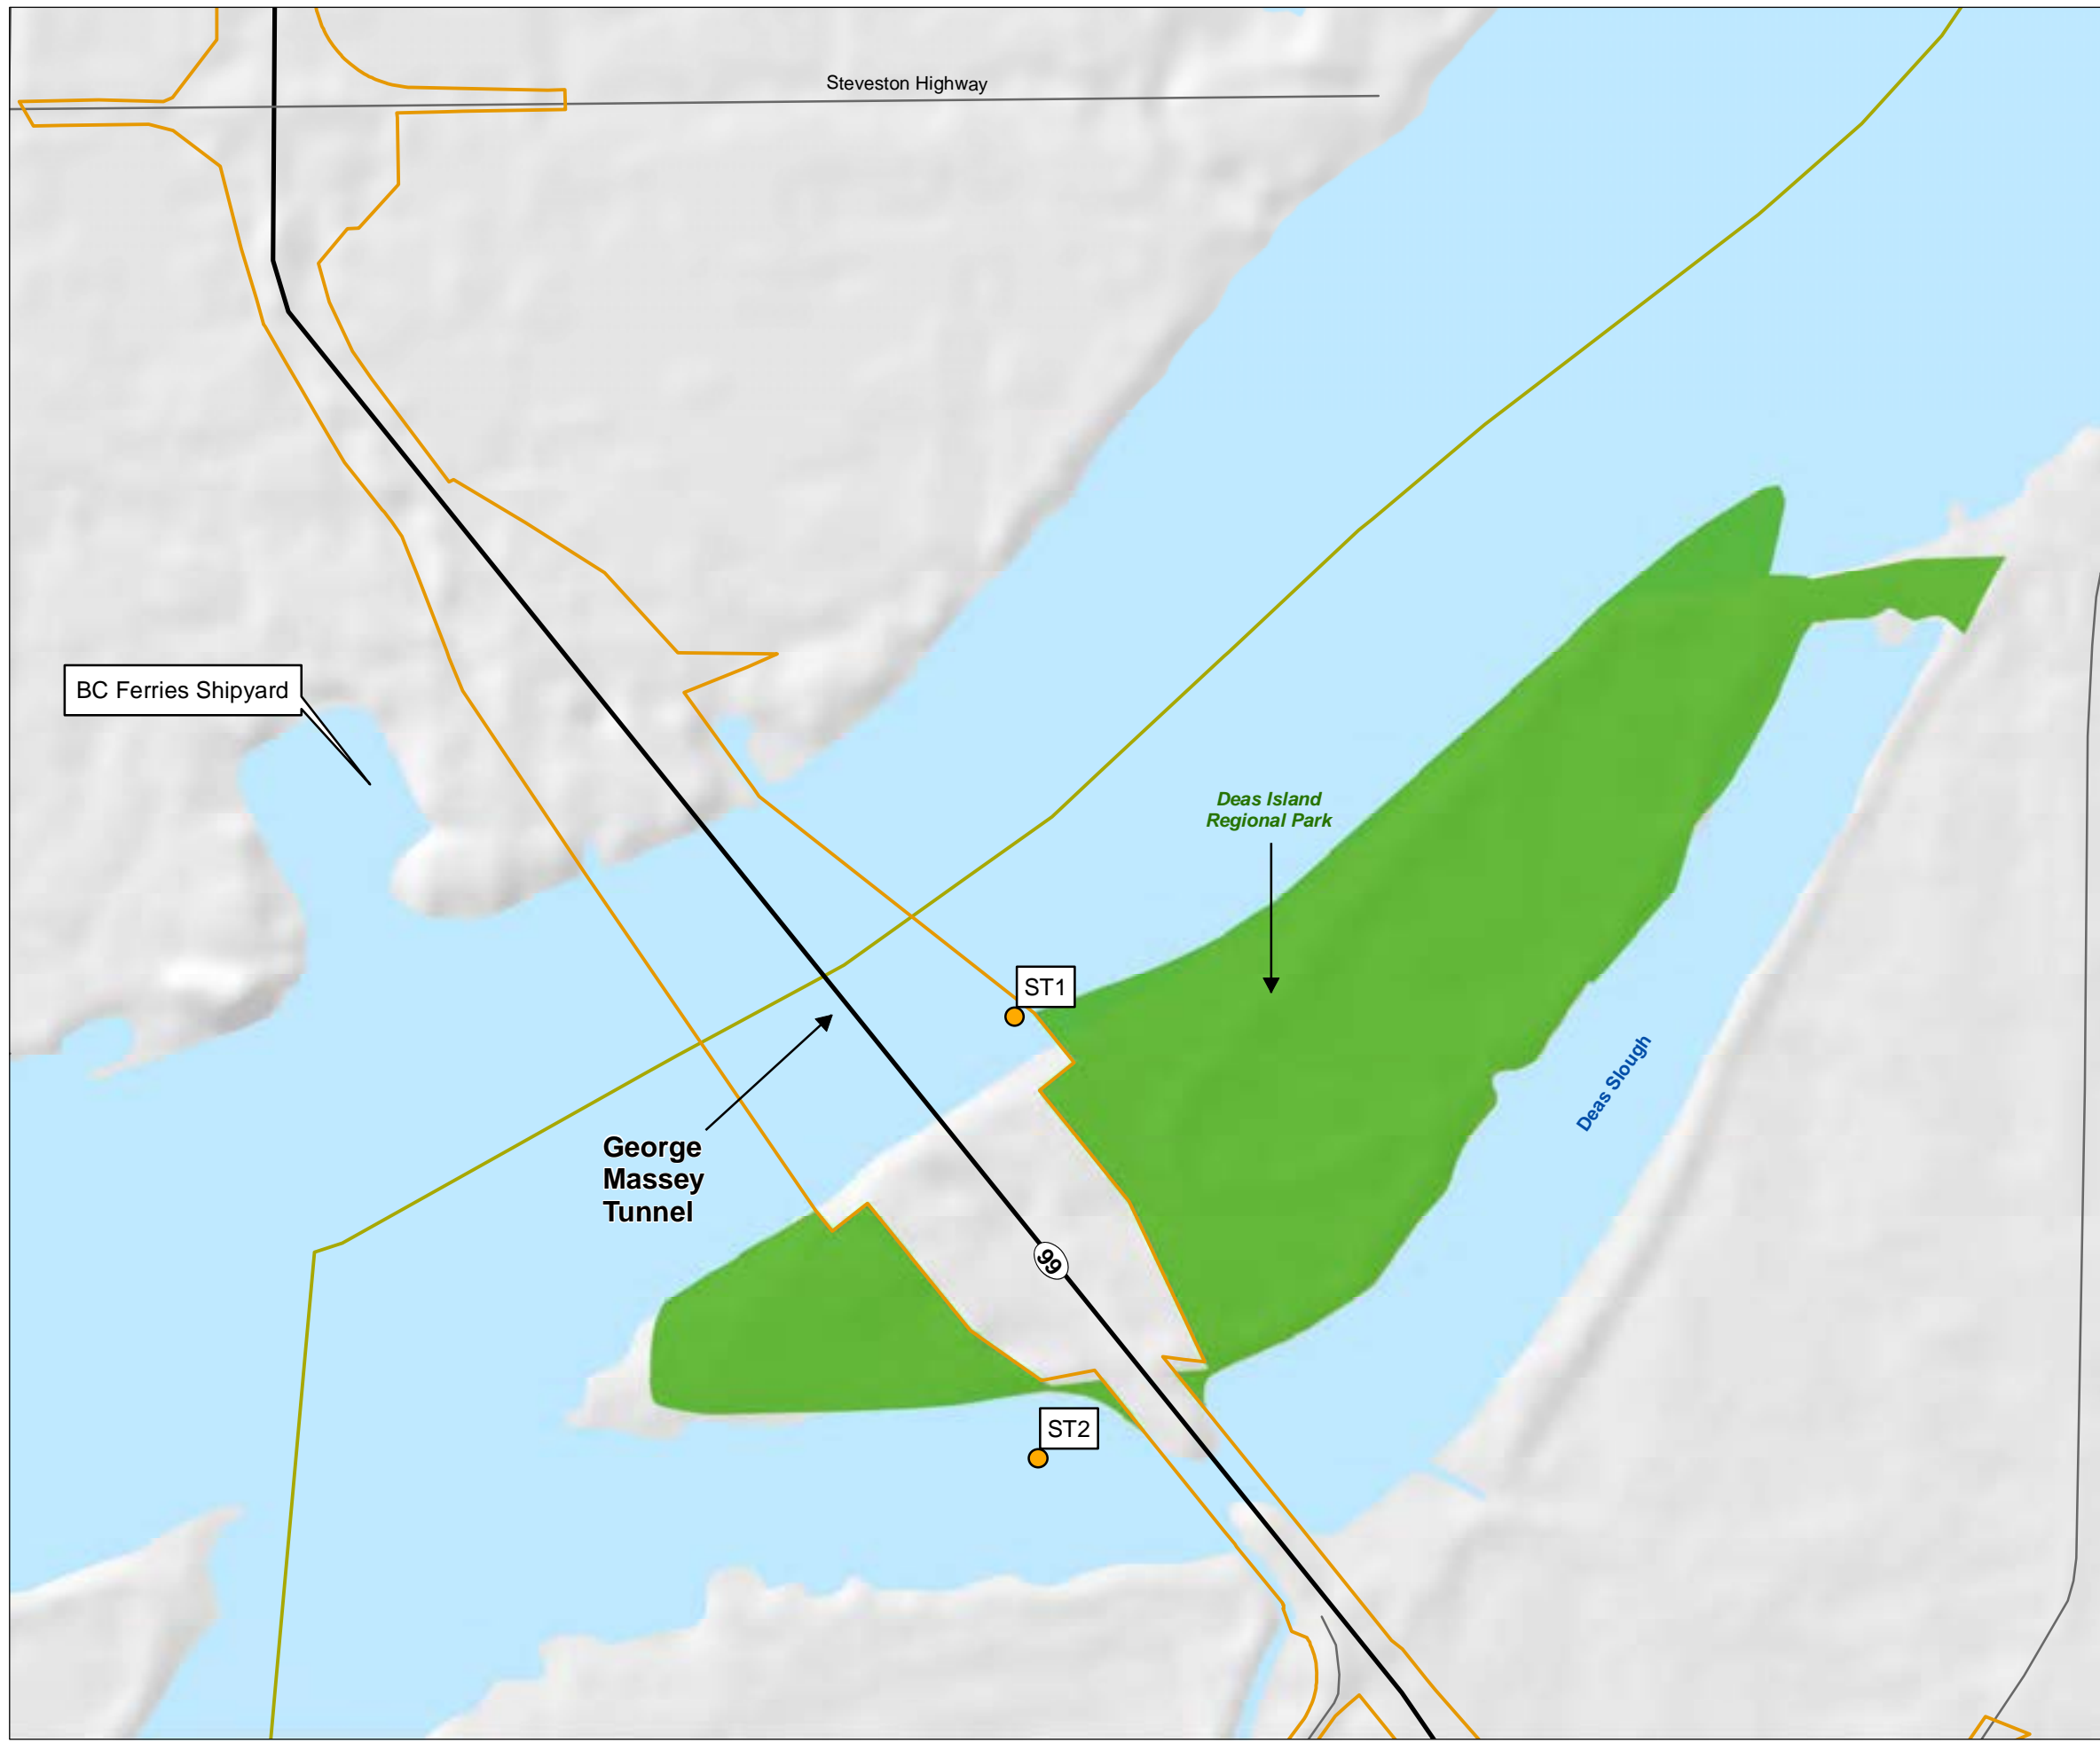

The assessment boundaries for underwater noise are defined below.

Spatial Boundaries

The assessment area includes those areas of the Fraser River South Arm, Deas Slough and Green Slough where noise generated by Project construction activities could potentially exceed background noise levels. Determination of the spatial extent of this zone is informed by the results of underwater sampling and modelling. The predicted extent of areas where potential Project-related change in underwater noise levels could influence receptor VCs (fish and marine mammals), based on results of modelling, is discussed in **Section 4.3.3**.

Underwater noise sampling at two locations, one in the Fraser River South Arm (ST1) and the other in Deas Slough (ST2) as shown on **Figure 4.3-1**, was undertaken to determine baseline noise levels in the identified zone. The sampling sites were selected based on proposed locations of Project-related activities that are likely to generate underwater sound that exceeds existing background ambient noise levels. Sampling stations were located near the banks of the river, off the main traffic routes, to prevent possible damage to instruments by passing vessels. Riverbed bathymetry of both the Fraser River South Arm and Deas Slough is fairly uniform close to the Tunnel construction site; therefore mean sound levels are not expected to vary substantially across the channels.

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on underwater noise were established based on the potential for the construction phase of the Project to interact with and have an effect on underwater noise. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, the construction phase of the Project includes components and activities that could interact with and affect underwater noise; therefore, the following temporal boundaries were defined for underwater noise assessment:

- Existing conditions
- Construction phase (including decommissioning of the Tunnel)
- Operations phase (including maintenance)

Temporal characteristics of the Project phases are discussed in **Section 1.1 Description of Proposed Project**.

Administrative Boundaries

No political, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects on underwater noise have been identified; therefore, no administrative boundaries are defined.

Technical Boundaries

Due to logistical considerations, underwater noise sampling locations were placed away from the marine traffic routes, closer to the riverbanks. This is not expected to influence the baseline measurements, since mean ambient noise levels are not expected to vary substantially across the width of the channel at either of the sampling locations.

4.3.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data, and describes the existing underwater noise conditions within the assessment area. An overview of the regulatory context for management of underwater noise as relevant to the Project is also provided. A brief overview of acoustic fundamentals and terminology that is relevant to the discussion of underwater noise is presented below.

Acoustic Fundamentals and Terminology

The terms noise level and sound level refer to sound pressure level (SPL)¹. As sound volume increases, there is a logarithmic increase in noise level. Therefore, to adequately express the very large range of pressure fluctuations, SPL is expressed on a logarithmic scale in decibels (dB), where an increase in sound energy by a factor of 10 corresponds to a 10 dB increase in sound level.

Several acoustic metrics are typically used to characterize the SPL of underwater sounds. These metrics, which may be presented in the form of graphs, tables, or maps, include root mean square (rms) SPL, peak SPL, and Sound Exposure Level (SEL).

The time-average sound pressure (expressed as rms SPL) quantifies the average pressure in a given time window of noise. The maximum instantaneous sound pressure is expressed as peak SPL. The total sound exposure, expressed as SEL, measures the total sound energy contained in one or more sound pulses.

4.3.2.1 Baseline Data Collection

To measure baseline underwater noise levels prior to any Project construction activities, an Autonomous Multichannel Acoustic Recorder (AMAR; JASCO Applied Sciences) was deployed in the Fraser River South Arm channel (ST1; **Figure 4.3-1**) and in Deas Slough (ST2; **Figure 4.3-1**) from May 9 to 11, 2014. The AMAR was precisely calibrated to accurately measure noise levels continuously for 48 hours over the frequency range of 10 to 64 kHz. The objective of measuring baseline noise levels was to provide a quantitative description of underwater ambient noise in the Project Area.

4.3.2.2 Regulatory Context

There are no regulatory thresholds for the management of underwater noise in Canada. Thresholds for marine mammals and fish recommended by the U.S. National Marine Fisheries Service (NMFS) and DFO have been adopted for this Project. These recommended thresholds are described below.

¹ SPL is equal to 10 times the logarithm of the square of the sound pressure, in units of Pascals, divided by the square of a standard reference sound pressure.

Auditory Injury Thresholds

Beyond certain thresholds, underwater noise has the potential to injure marine mammals and fish. Auditory injury thresholds, or the levels at which injury to hearing organs can occur, are provided in **Table 4.3-2** and **Table 4.3-3** and discussed in the following.

Based on a review of data on hearing, and physiological and behavioural responses of marine mammals to anthropogenic sound, Southall et al. (2007) proposed species-specific mathematical functions (referred to as M-weighting functions) to filter sounds so as to reduce the parts of the frequency spectrum that the species of interest do not hear well (**Table 4.3-2**). Harbour seals, Steller sea lions, and California sea lions, all of which are pinnipeds, are the main species of concern in the assessment area. The M-weighting function specific to pinnipeds has been applied in this analysis. Southall et al. (2007) recommended dual thresholds for auditory injury based on peak SPL and M-weighted 24-hour SEL (i.e., the total sound exposure level for animals exposed to sounds generated in a 24-hour period).

The U.S. National Marine Fisheries Service (NMFS) has applied an auditory injury threshold for pinnipeds based on the rms SPL of a single pulse (**Table 4.3-2**).

Table 4.3-2 Auditory Injury Thresholds for Pulsed Sounds from the U.S. National Marine Fisheries Service (NMFS) and Southall et al. (2007) for Pinnipeds in Water

| NMFS Level A Take Threshold rms SPL (dB re 1 µPa) | Southall et al. (2007) Peak SPL Threshold (dB re 1 µPa) | Southall et al. (2007) M-weighted 24-Hour SEL Threshold (dB re 1 µPa ² s) |
|---|---|--|
| 190 | 218 | 186 |

Note: dB re 1 µPa = Units for decibels for underwater noise

Table 4.3-3 summarizes the Interim Criteria for Injury to Fish from Pile Driving Activities (AIP) developed by the U.S. Fisheries Hydroacoustic Working Group (FHWG 2008) and Fisheries and Oceans Canada (DFO) (B.C. MPDCA 2003).

Table 4.3-3 FHWG (2008) and DFO (B.C. MPDCA 2003) Auditory Injury Thresholds for Fish

| Reference | Peak SPL (dB re 1 µPa) | SEL (dB re 1 µPa ² s) |
|-----------------------|------------------------|----------------------------------|
| FHWG (2008) fish ≥2 g | 206 | 187 |
| FHWG (2008) fish <2 g | 206 | 183 |
| DFO (2003) fish | 210 | - |

Behavioural Disturbance Criteria

For marine mammals, the area of potential disturbance is often taken as the zone where underwater noise levels exceed 120 dB rms SPL (NOAA 2015, Southall 2007). Behavioural disturbance, however, is complex and depends on factors such as exposure duration, noise source type, habituation, and exposure context.

Underwater noise does not have the potential to cause behavioural effects when it falls below the background ambient noise level.

4.3.2.3 Existing Conditions

Characterization of existing conditions of underwater noise within the study area is based on the results of the underwater acoustic field measurements. The ambient measurements from acoustic recordings show that shipping traffic is the dominant source of variability in the data above 100 Hz frequency band in the Fraser River South Arm (**Appendix A, Figure 1**) and above 1,000 Hz in Deas Slough (**Appendix A, Figure 2**).

Constant machinery noise, possibly originating from shore, is present in the background of the recordings. For both monitoring locations, a small number of relatively high-amplitude noise events (e.g., passing vessels) contribute most of the sound energy. Intermittent low-frequency (less than 50 Hz) noise was observed at both recording locations during two six-hour periods. The source of this low frequency noise could not be identified.

Distributions of the total SPL measured over a wide frequency range (broadband sound levels) in the Fraser River South Arm and in Deas Slough are presented in **Table 4.3-4**. Ambient measurements in the Fraser River South Arm exceed 120 dB re 1 μPa^2 , 20% of the time. The higher sound levels are primarily due to larger vessels, such as tugs and container ships, transiting the river. Ambient measurements in Deas Slough are substantially lower than in the main channel because vessel traffic in the slough consists primarily of smaller, slow-moving boats transiting to and from the marinas.

Table 4.3-4 Existing Distribution of the Broadband Sound Levels Measured in the Fraser River South Arm and Deas Slough

| Sampling Location | 5% Exceedance Level (dB re 1 μPa) | Median Level (dB re 1 μPa) | 95% Exceedance Level (dB re 1 μPa) |
|------------------------|---|--|--|
| Fraser River South Arm | 126.6 | 108.7 | 93.6 |
| Deas Slough | 99.3 | 91.9 | 82.4 |

² dB re 1 μPa is the standard unit of decibel measurement for underwater noise.

4.3.3 Potential Effects

This section provides a summary of anticipated changes to underwater noise related to the construction and operation of the Project. It also describes the methodology used to assess potential Project-related effects.

4.3.3.1 Project Interactions

A preliminary review of the potential effects of Project interactions on underwater noise, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Construction: Key Project-related construction activities with the potential to interact with underwater noise include the following:

- On shore ground improvements and pile driving for the new bridge piers.
- Localized in-stream ground improvement and pile installation for the clear span over Deas Slough.
- Removal of the four central Tunnel segments.
- Transportation of Tunnel segments for offsite recycling.

Operation: As the new bridge will have a clear span across the Fraser River South Arm, Project activities (including routine maintenance) are expected to have minimal influence on underwater noise.

An overview of potential interactions between Project activities and underwater noise during the construction and operation of Project components is provided in **Appendix B**.

4.3.3.2 Potential Effects

Project effects on underwater noise were assessed by modelling the expected underwater noise levels generated by Project activities. An overview of the underwater acoustic modelling that was completed is presented in this section. Further detail, including construction activities selected for modelling and the rationale for the selection, assumptions made regarding construction scenarios, equipment types, and source noise levels are provided in the technical volume, **Underwater Noise Modelling Study** included under **Section 16.3**.

The Marine Operations Noise Model was used to estimate the underwater sound levels associated with the following Project activities:

- Scenario 1: Pile driving along the edge of Deas Slough
- Scenario 2: Vibratory installation of piles along the edge of Deas Slough
- Scenario 3: Vibrodensification along the edge of Deas Slough
- Scenario 4: Cutter suction dredging to remove sediment overlying the Tunnel
- Scenario 5: Tug and barge activity when Tunnel segments are being removed
- Scenario 6: Simultaneous removal of sediment and riprap, and tug and barge activity during Tunnel removal

The results of the Marine Operations Noise Model were used to generate visual maps of peak SPL, rms SPL, and SEL for each of the six scenarios. The reported sound levels were applied as the maximum levels over all depths that were modelled.

Potential Effects

Human-generated noise, referred to as anthropogenic noise, is commonly categorized as pulsed or non-pulsed sounds. Pulsed sounds are brief (less than few seconds) and intermittent, with rapid changes of sound pressure (e.g. an impact-hammer strike). Non-pulsed sounds are characterized by gradual changes in sound pressure over time (e.g., marine vessels transiting and a vibratory pile driver in operation).

Effects from Pulsed Noise Sources

The highest level of pulsed noise is anticipated to be generated by pile driving along the edge of Deas Slough. Results of underwater noise modelling of the scenario involving 100 minutes (3,500 blows) of impact pile-driving along the edge of Deas Slough indicate that the potential extent of acoustic injury zone (defined by the two FHWG SEL threshold criteria, FHWG 2008) associated with this activity will be within 700 m for fish weighing less than two grams, and approximately 600 m for fish weighing two grams or more. Modelling results also indicate that underwater noise levels generated by the modelled scenario would be lower than the thresholds recommended for preventing auditory injury in pinnipeds, as per Southall et al. (2007), beyond 600 m from the source. These predictions are considered conservative because in arriving at them, the model assumes that the receiver (i.e., fish or marine mammal) is stationary for the duration of the sound exposure. Avoidance behaviour by marine mammals and fish would lessen their overall sound exposure and thus reduce the duration of time they would spend in the injury zone for impact pile-driving.

The modelling scenario assumed pile driving along the edge of Deas Slough through a maximum water depth of five metres, which corresponds to a high tide. Much of the actual Project-related construction along the edge of Deas Slough would occur under lower water conditions or in the dry with low tide. As such, actual underwater noise levels generated by pulsed sources associated with Project construction are expected to be lower than the values predicted through modelling.

Effects of Non-Pulsed Noise Sources

Of the non-pulsed noise sources modelled, cutter suction dredging was found to generate the highest levels of underwater noise. The extent within which the behavioural disturbance threshold for marine mammals (120 dB re 1 μ Pa SPL zone) was reached was smallest (0.44 km) for tug and barge activities associated with crane lift of the Tunnel segments. Noise generated by tug and barge traffic associated with the Project was found similar to existing ambient noise levels in the Fraser River South Arm, where the behavioural disturbance threshold for marine mammals is exceeded 20% of the time, primarily due to larger vessels such as tugs and container ships transiting in the river. Of the non-pulsed noise sources modelled, a combination of cutter suction dredging, rip rap removal, and tug and barge operations was found to create the largest zone (3.45 km) where the behavioural disturbance threshold for mammals is exceeded.

Although vibratory pile driving was identified as the source of highest level of non-pulsed noise, modelling results indicated that noise from this activity was concentrated at low frequencies (< 200 Hz), which dissipate rapidly in the shallow sediments of Deas Slough, confining the zone where the marine mammal behavioural disturbance threshold is reached to a relatively small (0.6 km) extent within Deas Slough.

Sound is strongly attenuated in shallow water such as Deas Slough because of increased bottom loss due to absorption of sound energy by sediments. Furthermore, bottom loss is enhanced by soft sediments such as silt and clay, which are more absorptive than harder materials like sand and gravel. As a result, noise from construction activities is expected to attenuate more rapidly with distance in Deas Slough than in the Fraser River South Arm. In Deas Slough, sound propagation is further restricted by Deas Island and the surrounding riverbank.

4.3.4 Mitigation Measures

A hierarchical approach, based on avoidance of potential effects followed by minimization or reduction of unavoidable effects, was used in identifying strategies to mitigate potential Project-related effects on underwater noise.

Measures to avoid potential effects have been/will be incorporated into project considerations such as site and route selection, scheduling, design, and construction and operation procedures and practices. Where potential effects cannot be avoided through project considerations, standard mitigation measures, best management practices (BMP), and construction and operational environmental management plans (EMPs) will be implemented to minimize potential Project-related effects or reduce them to acceptable levels. These measures are described in general terms below.

4.3.4.1 Avoidance

The new bridge will span the Fraser River from bank to bank without the need for any permanent works below the high water level. This approach has been taken to avoid, as much as possible, Project-related effects on the river and sloughs, including generation of underwater noise during construction and operation. Similarly, a clear span is proposed over Deas Slough as well.

Propagation of underwater noise from activities such as driving piles along the edges of Deas Slough, which are the primary sources of Project-related underwater noise, can be mitigated effectively by avoiding undertaking them in water. Scheduling such activities during periods of low tide, when work can be completed under shallow water conditions or in the dry, is expected to minimize potential effects on underwater noise.

4.3.4.2 Minimization

In instances where avoidance of underwater noise propagation cannot be achieved through scheduling, environmental protection measures will be implemented to avoid or minimize the effect of Project-related change in underwater noise conditions on receptors (fish and marine mammals). These measures, which will involve monitoring and mitigation of underwater noise, will be outlined in a Marine Mammal Management Plan included under the Construction Environmental Management Plan (CEMP) for the Project as described in **Section 12.0 Management Plans**.

The Marine Mammal Management Plan will include a description of standard best practices and mitigation measures that will be implemented to minimize the effects of underwater noise generated during marine-based construction activities. Mitigation and monitoring measures for underwater noise described in the plan will include, but will not be limited to:

- Limited use of engines and propellers on stationary vessels, whenever possible.
- Maintaining consistent navigation courses and speeds.
- Conducting land-based pile driving whenever possible.
- Conducting activities with the potential to generate underwater noise as efficiently as possible.
- Avoiding unnecessary idling of marine-based equipment.
- Implementation of marine mammal monitoring during activities anticipated to generate underwater noise, including an underwater noise monitoring program.
- Underwater noise monitoring conducted during Project construction activities that have the potential to generate underwater sound levels that may exceed auditory thresholds that can cause physical injury to fish or marine mammals.

Underwater noise monitoring will be conducted using a hydrophone at the onset of pile driving activities to confirm the results of this assessment and ensure underwater noise levels do not exceed auditory injury thresholds as described in **Section 4.3.2.2**. If warranted by the results of monitoring, additional mitigation measures (e.g., bubble curtains or sound-damping sleeves) will be deployed.

Measures identified above are standard best practices proven to be effective in managing underwater noise levels during in- or near-water construction. Specific mitigation measures such as deployment of bubble curtains and sound-damping sleeves are proven techniques shown to reduce underwater pile driving sound levels by 10 dB or more (ICF Jones and Stokes, and Illingworth and Rodkin Inc. 2009).

4.3.5 Residual Effects

As discussed in **Section 4.3.3.1**, the new bridge will have a clear span across the Fraser River South Arm and Deas Slough, and post-construction activities (including routine maintenance) are expected to have minimal influence on underwater noise. Therefore, no residual adverse effects on underwater noise are expected post construction.

Implementation of mitigation measures during pile driving, as discussed in **Section 4.3.4**, including construction scheduling that allows noise-generating activities to be undertaken in shallow water or in the dry, are expected to avoid or minimize the potential to generate pulsed sounds at levels capable of inducing auditory injury in marine mammals and fish.

In-water construction activities, specifically those associated with Tunnel decommissioning, are expected to generate temporary, localized increases in non-pulsed noise levels during Project construction. Implementation of mitigation measures discussed in **Section 4.3.4** are expected to minimize the potential to generate underwater noise levels above the baseline condition.

Unavoidable temporary construction-related effects on underwater noise are categorized as follows, and characterized below in terms of the direction, magnitude, extent, duration, frequency, reversibility, and likelihood of the effect:

- Residual effect #1: Effects from pulsed noise sources (e.g. impact pile driving)
- Residual effect #2: Effects from non-pulsed noise sources (e.g. removal of Tunnel segments and overlying material)

Definitions for ratings applied to residual effects criteria, developed with specific reference to underwater noise, are presented in **Table 4.3-5**. Summary of criteria ratings for the potential residual effects is provided in **Table 4.3-6** and **Table 4.3-5**. Context for the characterization of the residual effect, i.e. sensitivity/resilience of underwater noise conditions to potential Project-related effects, based on existing conditions, is also provided. Given the close link between Potential Project-related changes in underwater noise conditions and effects on receptor VCs—i.e. fish and fish habitat, and marine mammals—characterization of residual effects is presented in the context of their influence on receptor VCs. Specifically, the magnitude of potential residual effects is discussed in terms of potential for increase in underwater noise levels to cause behavioural disturbance or auditory injury in fish or marine mammals.

Table 4.3-5 Criteria Used to Characterize Residual Effects on Underwater Noise

| Criteria | Description | Definition of Rating | |
|-----------|--|----------------------|--|
| Direction | Overall nature of the residual effect | Adverse | Negative effect as a result of the Project. |
| | | Positive | Beneficial effect as a result of the Project. |
| | | Neutral | Neutral effect as a result of the Project. |
| Magnitude | Intensity of the effect relative to natural or baseline conditions | Negligible | No measurable change in underwater noise level |
| | | Low | A measurable change within natural variability, and not expected to affect receptor VCs (i.e. fish and marine mammals) |
| | | Moderate | A measurable change outside the range of natural variability, but not expected to result in substantive effects on receptor VCs. |
| | | High | A measurable change outside the range of natural variability and potentially harmful to receptor VCs. |
| Extent | Geographic extent / distribution of the residual effect | Site | Effect is restricted to the immediate Project alignment. |
| | | Local | Effect is restricted to the LAA. |
| | | Regional | Effect extends beyond the LAA |
| Duration | Length of time over which the residual effect is expected to persist | Short term | Effect occurs for a limited period during Project construction and does not persist beyond several hours at a time. |
| | | Moderate term | Effect persists over a period of days to weeks during construction. |
| | | Long term | Effect persists beyond construction phase, or Change is permanent. |

| Criteria | Description | Definition of Rating | |
|---------------|---|----------------------|--|
| Frequency | Nature of the occurrence of the residual effect (e.g., how often the stressor affects the IC) | Rare | Effect occurs for a limited number of times during Project construction or operation. |
| | | Uncommon | Effect occurs intermittently during Project construction or operation. |
| | | Frequent | Effect occurs frequently during Project construction or operation. |
| | | Continuous | Effect occurs continuously during Project construction or operation. |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after the disturbance has ceased (or after a period of time after the disturbance has ceased) | Reversible | Baseline conditions will be naturally restored after disturbance has ceased. |
| | | Irreversible | Baseline conditions will not be naturally restored after disturbance has ceased. |
| | | Change | Effect may fluctuate between positive and adverse for the duration of the disturbance. |
| Likelihood | Likelihood that the residual effect may occur | Low | Likelihood of residual effect is less than 10%. |
| | | Moderate | Likelihood of residual effect is between 10% and 25%. |
| | | High | Likelihood of residual effect is greater than 25%. |

4.3.5.1 Residual Effect #1: Effects from Pulsed Noise Sources

After implementing mitigation measures discussed in **Section 4.3.4**, potential impact pile driving along the edges of Deas Slough is not expected to expose fish or marine mammals to pulsed noise levels capable of inducing auditory injury. Nonetheless, residual pulsed noise at lower levels (including sediment-borne vibration) has the potential to temporarily cause behavioural disturbance and mask sounds used for foraging and communication of marine mammals and fish. **Table 4.3-6** presents a summary of the criteria ratings for this residual effect.

Table 4.3-6 Criteria Ratings for Construction-related Effects from Pulsed Noise Sources

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|---|
| Direction | Adverse | Noise-generating construction activities (specifically pile driving) near the shoreline have the potential to result in a temporary increase in underwater noise levels. |
| Magnitude | Moderate | Majority of noise-generating activities near the shoreline are expected to be undertaken in shallow water or in the dry. With monitoring and mitigation, the resulting changes will be below levels that injure fish or marine mammals. |
| Extent | Local | Spatial extent will be restricted to the LAA. |
| Duration | Short term | Effect will occur only during specific noise-generating construction activities undertaken in water, and is not expected to persist beyond the duration of such activities. |
| Frequency | Rare | Effect will occur only in the rare instance where undertaking a noise-generating activity in water cannot be avoided through management of the construction schedule. |
| Reversibility | Reversible | Underwater noise conditions will return to baseline conditions as soon as the contributing activity ceases. |
| Likelihood | Low | Noise-generating activities near the shoreline are expected to be undertaken in shallow water or in the dry, during low tides, minimizing the probability of a measurable change in underwater noise. |

4.3.5.2 Residual Effect #2: Effects from Non-Pulsed Noise Sources

In-water activities associated with construction, including removal of Tunnel segments and overlying material, and vibrodensification, will add to underwater noise levels in the river. Noise from these activities has the potential to cause behavioural disturbance and mask sounds used for foraging and communication of marine mammals and fish. **Table 4.3-7** presents a summary of the criteria ratings for this temporary, construction-related residual effect.

Table 4.3-7 Criteria Ratings for Effects from Non-Pulsed Noise Sources

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|--|
| Direction | Adverse | Noise-generating construction activities in or immediately adjacent to water have the potential to result in a temporary increase in underwater noise levels. |
| Magnitude | Low to Moderate | Noise from construction activities are expected to be temporary and localized, and fall within the present range of sound levels generated by vessel traffic in the river. |
| Extent | Local | Spatial extent will be restricted to the LAA. |
| Duration | Short term | Effect will occur only during specific noise-generating construction activities undertaken in water, and is not expected to persist beyond the duration of such activities. |
| Frequency | Uncommon | Effect will occur only during specific noise-generating construction activities undertaken in water, including removal of Tunnel segments and overlying material, and vibrodensification |
| Reversibility | Reversible | Underwater noise conditions will return to baseline conditions as soon as the contributing activity ceases. |
| Likelihood | High | There is estimated to be a greater than 25% probability that a measurable change in underwater noise will occur during in-water construction and Tunnel decommissioning activities. |

Context: The Fraser River South Arm is an active marine transportation corridor, and existing underwater noise levels in the Project area, dominated by noise from vessels transiting the river, are relatively high. Sensitivity of underwater noise conditions in the river to temporary, short-term changes resulting from in-water construction activities, including Tunnel decommissioning, is therefore considered to be low.

When examining the characteristics of residual effects of construction, including Tunnel removal, on underwater noise, it is important to appreciate that the characterization criteria as discussed above are applied to underwater noise as an IC. Characterization of potential effects of changes in underwater noise conditions on receptor VCs is included in the respective VC effects assessment sections (i.e. **Section 4.4 Fish and Fish Habitat** and **Section 4.6 Marine Mammals**).

4.3.6 Cumulative Effects Assessment

Where Project-related construction results in a temporary, short-term increase in underwater noise levels in the Fraser River South Arm, Deas Slough, or Green Slough, such changes are not anticipated to overlap spatially or temporally with other projects or activities and result in cumulative effects.

4.3.7 Follow-up Strategy

Underwater noise monitoring will be conducted using a hydrophone at the onset of pile driving activities to confirm the results of this assessment and ensure underwater noise levels do not exceed applicable auditory injury thresholds for marine mammals and fish.

No post-construction underwater noise monitoring or follow-up is proposed as no potential Project-related effects on underwater noise is anticipated after completion of construction.

4.4 Fish and Fish Habitat Assessment Highlights:

- The proposed bridge will have a clear span over the Fraser River South Arm and Deas Slough, avoiding or minimizing Project-related effects on fish and fish habitat.
- The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, resulting in a net environmental benefit for fish and fish habitat.
- Mitigation, including timing windows for undertaking in-stream works and other measures outlined in Project-related Environmental Management Plans, will ensure that potential effects on fish and fish habitat are effectively addressed.
- Given the disturbed nature of much of the Project alignment, revegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by:
 - Improvements to local water quality through Project-related improvements in stormwater management
 - Removal of non-native species
 - Replanting with species that provide habitat value for fish and wildlife.
- No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

4.4 Fish and Fish Habitat Assessment

This section presents the results of the assessment of potential Project effects on fish and fish habitat and includes the rationale for selecting fish and fish habitat as a valued component (VC), identification of Project-related effects, proposed approaches to mitigation, and evaluation of residual Project-related and cumulative effects. Monitoring to be conducted with respect to fish and fish habitat is also described.

Project-related changes in other environmental components along the pathway of effects of the Project—specifically, river hydraulics and morphology, sediment and water quality, and underwater noise—have the potential to affect fish and fish habitat. These intermediate components (ICs) and potential effects of the Project on them are discussed in the following sections: **Section 4.1 River Hydraulics and River Morphology**, **Section 4.2 Sediment and Water Quality**, and **Section 4.3 Underwater Noise**.

4.4.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on fish and fish habitat in terms of Project setting, and defines the assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

4.4.1.1 Assessment Context

The lower Fraser River and estuary provide habitat for fish species of high ecological, social, cultural, and commercial value. Fish species important to the viability of commercial, recreational, and Aboriginal (CRA) fisheries¹ include salmonids (family Salmonidae), eulachon (*Thaleichthys pacificus*), and sturgeon (*Acipenser* spp.). Salmonids use the lower Fraser River during adult spawning migration, and juvenile outmigration to marine environments. Juvenile salmonids and sturgeon rear and overwinter in brackish habitats. Eulachon migrate upstream to spawning habitats in the lower Fraser River and the mouths of large tributaries. Additional information supporting the selection of fish and fish habitat as a VC is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**.

4.4.1.2 Methodology

The assessment of fish and fish habitat follows the general methodology described in **Section 3.0 Assessment Methodology** and applied to all VCs. Building on this approach, the assessment of fish and fish habitat was designed to focus on specific species considered most appropriate in the context of existing conditions in the Project alignment. In this context, the assessment of fish and fish habitat focuses on five sub-components as presented in **Table 4.4-1**. Life history requirements and status of sub-components are summarized in **Section 4.4.2.3** and described in detail in the technical volume, ***Fish and Fish Habitat Study*** included under **Section 16.4**.

¹ As defined under the *Fisheries Act* R.S.C. 1985, c. F-14 (as amended on February 26, 2015), “commercial” in relation to a fishery, means that fish is harvested under the authority of a licence for the purpose of sale, trade or barter; “recreational”, in terms of a fishery, means that fish is harvested under the authority of a licence for personal use of the fish or for sport; and “Aboriginal”, in relation to a fishery, means that fish is harvested by an Aboriginal organization or any of its members for the purpose of using the fish as food, for social or ceremonial purposes or for purposes set out in a land claims agreement entered into with the Aboriginal organization;

Table 4.4-1 Sub-components for Fish and Fish Habitat

| Sub-component | Rationale for Selection |
|--|--|
| Salmon Chinook salmon Chum salmon Coho salmon Pink salmon Sockeye salmon | Pacific salmon are important to Aboriginal Groups and are also harvested commercially and recreationally. Pacific salmon and their habitat are managed by DFO under the <i>Fisheries Act</i> and are listed within the B.C. Conservation Framework with a goal of preventing the species from becoming at risk. |
| Sturgeon Green sturgeon White sturgeon | Sturgeon are protected under the <i>Fisheries Act</i> and are of traditional importance to Aboriginal Groups. White sturgeon support a Fraser River catch-and-release recreational fishery. They are also important for conservation. White and green sturgeon are listed as Endangered and of Special Concern, respectively, under SARA Schedule 1, and both are provincially Red-listed. |
| Eulachon | Eulachon are protected under the <i>Fisheries Act</i> and are of traditional importance to Aboriginal Groups. Eulachon are also important for conservation as they are provincially Blue-listed and designated as Endangered by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). |
| Trout Coastal cutthroat trout Rainbow/steelhead trout | Trout are protected under the <i>Fisheries Act</i> , are of importance to Aboriginal Groups, and support recreational fisheries in the Fraser River. Coastal cutthroat trout are also important for conservation as they are provincially Blue-listed. |
| Char Dolly Varden Bull trout | Char are protected under the <i>Fisheries Act</i> and are of traditional importance to Aboriginal Groups. Char support recreational fisheries in the Fraser River. Bull trout are also important for conservation as they are provincially Blue-listed and designated as Special Concern by COSEWIC. |

Likelihood of injury or mortality, and change in habitat conditions were used as indicators to assess fish and fish habitat trends within the assessment area and evaluate potential Project-related effects. The indicators chosen for the assessment of Project-related effects on fish and fish habitat and the rationale for their selection are presented in **Table 4.4-2**.

Table 4.4-2 Indicators for Fish and Fish Habitat

| Indicator | Rationale for Selection |
|---|--|
| Likelihood of injury or mortality of fish | <p>This indicator will be used to assess Project-related physical injury or direct mortality to fish.</p> <p>Causing death of fish is prohibited under the <i>Fisheries Act</i> based on the definition of serious harm to fish.</p> <p>Killing or harming of listed fish species is prohibited under <i>SARA</i>.</p> |
| Total suspended solid (TSS) levels (mg/L) and Turbidity (nephelometric turbidity units (NTU)) | <p>This indicator will be used to assess the potential for physical injury or direct mortality to fish resulting from elevated TSS levels, and changes in fish habitat quality from induced turbidity.</p> <p>Increase in TSS and turbidity levels will be evaluated against Canadian Council of Ministers of the Environment (CCME) <i>Water Quality Guidelines for the Protection of Aquatic Life</i> (CCME 2002) and B.C. <i>Approved Water Quality Guidelines 2006 Edition</i> (B.C. MOE 2006a).</p> |
| Underwater sound levels (SPL _{peak} and SEL _{cum}) | <p>This indicator will be used to assess Project-related physical injury (including direct mortality) to fish, and changes in fish habitat quality associated with elevated underwater sound levels.</p> <p>Increase in underwater sound levels will be evaluated against the Fisheries Hydroacoustic Working Group (2008) thresholds and the B.C. Marine and Pile Driving Contractors Association (2003) thresholds, as recommended by DFO.</p> |
| Loss of habitat area (ha) | <p>This indicator will be used to assess Project-related changes in habitat availability.</p> <p>Permanent alteration or destruction of fish habitat is defined and governed under the <i>Fisheries Act</i>, based on the definition of serious harm to fish.</p> |

4.4.1.3 Assessment Boundaries

Spatial and temporal boundaries identified for the assessment of Project-related effects on fish and fish habitat and the rationale for selecting them are discussed below. No political, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects on fish and fish habitat, or accessibility constraints or gaps in data that could limit the ability to predict the effects of the Project were identified; therefore administrative and technical boundaries have not been defined for this VC and are not discussed further.

Spatial Boundaries

The local assessment area (LAA) and regional assessment area (RAA) for fish and fish habitat are defined in **Table 4.4-3** and shown in **Figure 4.4-1**.

Table 4.4-3 Spatial Boundary Definitions for Fish and Fish Habitat

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|--|
| Local Assessment Area (LAA) | Fraser River South Arm extending from approximately the middle of Shady Island to 500 m upstream of the Project alignment, and Project alignment plus 30 m on either side of the Project alignment in upland areas. |
| Regional Assessment Area (RAA) | Section of the Fraser River South Arm (including Canoe Pass) extending from the river mouth to 1,000 m upstream of the Project alignment, and Project alignment plus 500 m on either side of the Project alignment in upland area. |

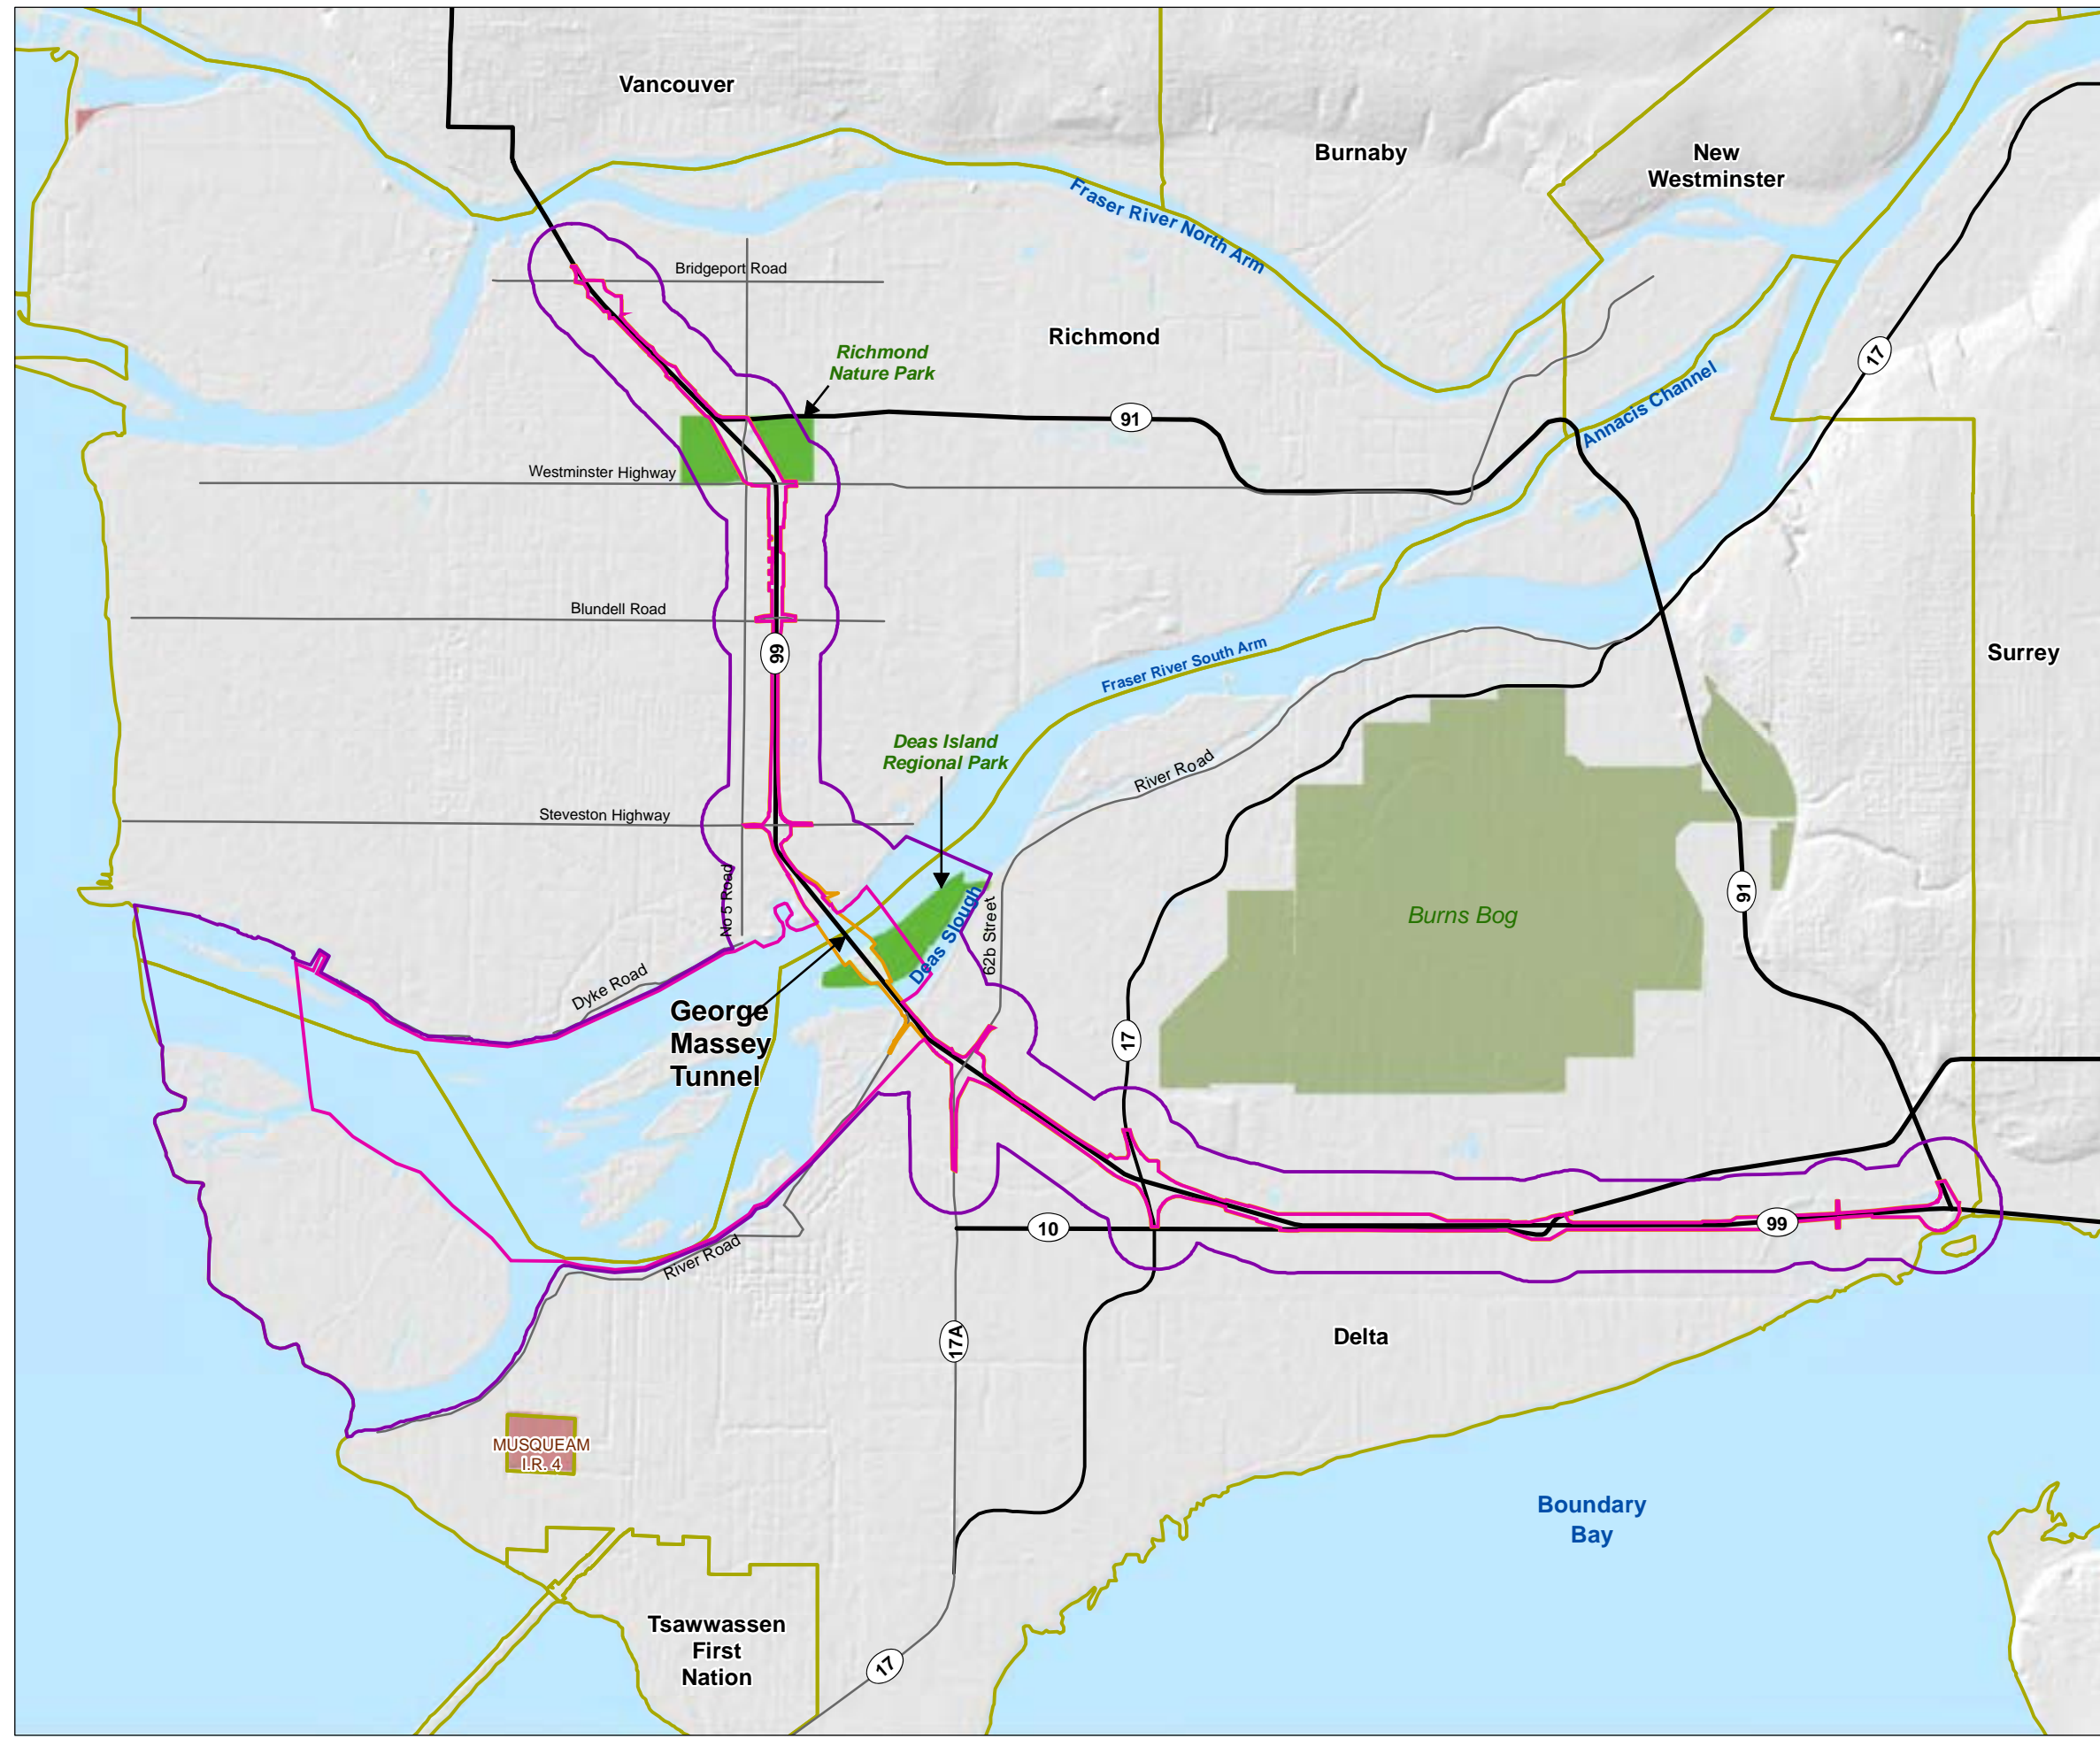

The LAA was established to encompass the area within which the Project is expected to most likely interact with, and potentially have an effect on, fish and fish habitat. In determining the LAA boundaries, consideration was given to the nature and characteristics of fish and fish habitat, potential exposure of fish and fish habitat to various influences (e.g., elevated total suspended solids (TSS), underwater noise), and the maximum extent of potential Project-related effects on fish and fish habitat.

The RAA was established to provide a regional context for the assessment of Project-related effects. The RAA was also established to encompass the area within which the residual effects of the Project on fish and fish habitat may combine with the effects of other projects and activities to result in potential cumulative effects.

Temporal Boundaries

The temporal boundaries for the assessment of fish and fish habitat include the existing conditions of the LAA and RAA, the Project construction phase (including decommissioning of the Tunnel), and the Project operations phase (i.e., the new bridge and upgraded highway in operation). Temporal characteristics of the Project’s construction phase, including decommissioning of temporary construction-related facilities, and the operations phase are defined in **Section 1.1 Description of Proposed Project**.

Project-related construction activities are likely to occur during sensitive life periods of sub-components. For juvenile fish (e.g., Pacific salmon and white sturgeon), these life periods include rearing, foraging, and overwintering. For adult fish, sensitive periods include adult spawning migration (e.g., Pacific salmon and eulachon).

4.4.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data, and describes the existing conditions of fish and fish habitat within the assessment areas. An overview of the regulatory context for management of fish and fish habitat as relevant to the Project is also provided.

4.4.2.1 Baseline Data Collection

In 2014, the Ministry initiated studies on fish and fish habitat to support Project planning and assessment. Building on available information, these studies were designed to address known data gaps. Desktop and field studies conducted with respect to fish and fish habitat are summarized in **Table 4.4-4**.

Table 4.4-4 Desktop and Field Studies Related to Fish and Fish Habitat

| Study Name | Purpose of Study |
|---------------------------|--|
| Desktop literature review | <ul style="list-style-type: none">• Determine fish habitat values and fish species use of watercourses within the study area• Identify key data gaps and areas of uncertainty within the study area |
| Freshwater fish sampling | <ul style="list-style-type: none">• Verify and update available information on fish species use of watercourses within the study area, focusing on data gaps |
| Fish habitat assessment | <ul style="list-style-type: none">• Assess the quality of fish habitat in watercourses within the study area, focusing on data gaps |

In addition, the results of modelling conducted to evaluate potential Project-related changes to river hydraulics and morphology (see **Section 4.1 River Hydraulics and River Morphology**) and underwater noise using a Marine Operations Noise Model (see **Section 4.3 Underwater Noise**) were used to assess potential effects of the Project on fish and fish habitat.

Information provided by Aboriginal Groups during pre-Application consultation has been provided, where applicable, in the discussion of existing conditions.

Given that existing conditions and trends of fish and fish habitat in the lower Fraser River are well-known, field sampling efforts focused on channelized watercourses along existing highway infrastructure (referred to hereafter as upland ditches, for sake of consistency) where fish presence and fish habitat values are less well studied and less documented. Fish and fish habitat sampling was conducted in watercourses that parallel or intersect the Highway 99 right-of-way (ROW) within the LAA. Descriptions of fish and water quality sampling, aquatic habitat assessment methods, data management and analysis are provided in the technical volume, ***Fish and Fish Habitat Study*** included under **Section 16.4**.

Based on the results of the desktop and field studies, watercourses within the LAA were classified for the purposes of this assessment based on CRA fisheries values as follows:

- Red: year-round habitat for CRA or listed fish species
- Dashed-red: seasonal (e.g., overwintering) habitat for CRA or listed fish species
- Orange: significant upstream source of food or nutrients to Red or Dashed-red habitat
- Yellow: non-CRA fish bearing and with no value to CRA or listed fish species
- Green: no value for fish (CRA, listed, or other fish species)

4.4.2.2 Regulatory Context

Regulation and management of fish and fish habitat in B.C. occurs primarily through the following federal and provincial legislation:

- Federal *Fisheries Act*, R.S.C. 1985, c. F-14 (as amended on February 26, 2015)
- Federal *Species at Risk Act (SARA)*, S.C. 2002, c. 29
- B.C. *Water Sustainability Act*, SBC 2014, c. 15
- B.C. *Wildlife Act*, RSBC 1996, c. 488

The *Fisheries Act*, administered by Fisheries and Oceans Canada (DFO), protects the ongoing productivity and sustainability of CRA fisheries. Any work, undertaking, or activity that results in serious harm to fish² that are part of, or support, CRA fisheries is prohibited. The *Fisheries Act* also prohibits the deposition of deleterious substances in water frequented by fish, unless authorized by regulations under the *Fisheries Act* or other federal legislation.

² The *Fisheries Act* defines “serious harm to fish” as “the death of fish or any permanent alteration to, or destruction of, fish habitat”. “Fish”, in turn, is defined as (a) parts of fish, (b) shellfish, crustaceans, marine animals and any parts of shellfish, crustaceans or marine animals, and (c) the eggs, sperm, spawn, larvae, spat and juvenile stages of fish, shellfish, crustaceans and marine animals.

DFO is responsible for the protection of fish and fish habitat, including fish species listed under SARA. At-risk fish species that occur in the vicinity of the Project include white sturgeon (*Acipenser transmontanus*; SARA Schedule 1: Endangered) and green sturgeon (*A. medirostris*; (SARA Schedule 1: Special Concern) (Government of Canada 2006). At present, Endangered and Special Concern status is being considered for Fraser River and central Pacific coast populations of eulachon (DFO 2014a), and south coast populations of bull trout (*Salvelinus confluentus*) (DFO 2014b), respectively.

Changes in and about a stream require notification or approval under Section 11 of the B.C. *Water Sustainability Act*, administered by the B.C. Ministry of Forests, Lands, and Natural Resource Operations (FLNR). Under this Act, the term “stream” applies to natural and manmade watercourses, including channelized streams and constructed ditches.

Enacted under Section 12 of the B.C. *Fish Protection Act*, the Riparian Area Regulations (RAR), outlines requirements for establishment of development setbacks from streams, lakes, and wetlands and applies to lands under the jurisdiction of municipalities. The Ministry’s ROW is exempt from the RAR, and the regulation does not apply directly to the Project.

The B.C. *Wildlife Act* provides for the conservation and management of wildlife populations (including fish) and habitat. The Act also provides for assignment of species and ecological communities at risk in B.C. to one of three lists (Red, Blue, Yellow) by the B.C. Conservation Data Centre (CDC) based on provincial Conservation Status Rank³. Further explanation regarding the assignment of Conservation Status Rank by the CDC to species and ecosystems at risk is provided in **Section 4.7 Vegetation**.

Provincially-listed fish species occurring in the vicinity of the Project include the Red-listed white sturgeon and green sturgeon, and the Blue-listed coastal cutthroat trout (*Oncorhynchus clarkii clarkii*).

³ Red-listed species and ecological communities are Extirpated, Endangered, or Threatened in B.C., Blue-listed species and ecological communities are of Special Concern, and Yellow-listed species are considered to be secure. The legal designation as Endangered or Threatened under the Act increases the penalties for harming a species and enables the protection of habitat in a Critical Wildlife Management Area.

4.4.2.3 Existing Conditions

Fish Habitat

Fraser River South Arm

The Project is located approximately 18 km upstream of the Fraser River mouth, within a section of the Fraser River South Arm that is influenced by a tidally-driven salt water wedge that penetrates near the river bottom (Kostaschuk 2002). Annual maintenance dredging occurs at several locations within the South Arm (FREMP 2006, PMV 2014). Downstream of New Westminster, the river has deepened in response to dredging, training, and confinement by bridges and dikes. Further information on the lower Fraser River hydraulics and morphology is provided in **Section 4.1 River Hydraulics and River Morphology**.

Shoreline of the Fraser River South Arm is characterized by extensive industrial activity. A high proportion of habitat, including that in the Project alignment, is classified as of low (green-coded) or moderate (yellow-coded) productivity (**Figure 4.4-2**; BIEAP - FREMP 2014). Productive (red-coded) shoreline habitat is generally confined to a narrow band of intertidal marshes, mud- and sand-flats around Tilbury and Annacis islands (**Figure 4.4-2**; BIEAP - FREMP 2014). With respect to shoreline conditions in the Fraser River South Arm, during pre-Application consultation, Aboriginal Groups expressed concern regarding lack of shade from trees or areas for juvenile salmon to hide. For a detailed description of the lower Fraser River shoreline habitats in the LAA, and their respective FREMP designations, refer to the technical volume, **Fish and Fish Habitat Study** included under **Section 16.4**.

The lower Fraser River supports 42 species of fish (Richardson et al. 2000). Anadromous CRA species that rely on aquatic habitats in the Fraser River estuary include salmonids, sturgeon, and eulachon. Common non-CRA fish species that inhabit the lower Fraser River mainstem, sloughs, backwaters, and tributaries include: prickly sculpin (*Cottus asper*), peamouth (*Mylocheilus caurinus*), redbelt shiner (*Richardsonius balteatus*), northern pikeminnow (*Ptychocheilus oregonensis*), starry flounder (*Platichthys stellatus*), lamprey (*Lampetra* sp.), and threespine stickleback (*Gasterosteus aculeatus*) (Richardson et al. 2000).

Deas Slough

Deas Slough, a backwater feature of the Fraser River South Arm, is approximately 2,700 m long and 250 m wide, with an average depth of 5 m. Deeper sections exist in the vicinity of the two marinas on the slough's south bank, which are dredged to maintain boat access (FREMP 2006). In contrast to sandy sediments in the South Arm, substrate in the slough consists predominantly of silt and clay (Birtwell et al. 1987a). Deas Slough is tidally-influenced; however, a sill on the slough's bed at the mouth prevents salt water penetration in depths greater than 4 m (Birtwell et al. 1987a).

The slough's shoreline is designated primarily as highly productive (red-coded) habitat. In contrast, riprap-armoured shoreline in the vicinity of the Deas Slough Bridge is characterized as low (green-coded) to moderate (yellow-coded) productivity habitat (BIEAP - FREMP 2014). A detailed description of tidal foreshore habitats, riparian vegetation, and upland land uses surrounding Deas Slough is included in the technical volume, ***Fish and Fish Habitat Study*** included under **Section 16.4**.

| FRASER RIVER ESTUARY MANAGEMENT PROGRAM HABITAT INVENTORY | |
| Figure 4.4-2 | 13/05/2016 |
| | |

Deas Slough is used by a number of rearing and overwintering fish species. Rearing habitat has been documented for underyearling sockeye salmon (*Oncorhynchus nerka*), which are present in the slough from April to October, with numbers peaking in late June to late July (Birtwell et al. 1987b). Underyearling starry flounder also rear in the slough in spring and summer, and adult starry flounder are present in the slough in autumn and winter (Birtwell et al. 1993). Other fish species recorded in Deas Slough include, but are not limited to, chinook (*O. tshawytscha*), chum (*O. keta*), coho (*O. kisutch*), and pink salmon (*O. gorbuscha*), prickly sculpin, and threespine stickleback (FISS 2014).

Green Slough

Green Slough flows northeast along River Road West and then parallels Highway 99 before flowing into Deas Slough. Green Slough is 15 to 20 m wide along most of its length, but the channel narrows to about 9 to 10 m wide near the pump station at Crescent Slough. The channel is a low gradient glide, with silty substrates and uniform depths that range from about 0.9 to 1.5 m at low water.

Green Slough is tidally-influenced and drains into the lower reaches of Deas Slough and ultimately into the Fraser River South Arm, with unimpeded flows. Through the Green Slough Pump Station (5596 River Road), it drains agricultural and residential runoff from Crescent Slough in autumn and winter for flood protection, and irrigates agricultural lands in spring and summer (LGL et al. 2009). The pumps are not screened to prevent fish entrainment, and no fish deflection devices are employed at the station (LGL et al. 2009).

Green Slough is classified as an environmentally sensitive area under Delta's Official Community Plan (Delta 2014). The slough's shoreline is classified as habitat of high productivity (red-coded) (BIEAP - FREMP 2014). Marsh and riparian habitats of Green Slough are described in detail in the technical volume, ***Fish and Fish Habitat Study*** included under **Section 16.4**.

Green Slough provides perennially wetted rearing and overwintering habitat for salmonids (LGL et al. 2009). It is also used by non-salmonid species, such as threespine stickleback, prickly sculpin, and reidside shiner. Non-native fish species, such as carp (*Cyprinus carpio*) and black crappie (*Pomoxis nigromaculatus*), have also been reported in Green Slough (FISS 2014).

Upland Ditches

Of the 43.5 km of assessed ditches that parallel or intersect Highway 99 within the LAA, 5.2 km (12%) are coded as dashed-red, and 10.0 km (23%) as orange. The remaining ditches are of low or no value to CRA fish; 26.9 km are coded as yellow (62 %), and 1.5 km (3 %) are coded as green. A description of watercourse classification codes specific to this assessment is provided in **Section 4.4.2.3**.

Ditches within the LAA are low-gradient straight runs, with fine sediments, but without pools or riffles. In general, these ditches are poorly connected to the tidal waters of the lower Fraser River (e.g., located upland of flood control infrastructure, included floodgates and pump stations), which limits access for CRA fish. Instream vegetative cover is generally limited and riparian vegetation consists mainly of grassed roadside shoulders, shrubs lining ditch banks, backed by agricultural fields. A detailed assessment of upland ditch habitat within the LAA is included in the technical volume, ***Fish and Fish Habitat Study*** included under **Section 16.4**.

Previous sampling in upland ditches has resulted in the capture of non-CRA fish, including native (e.g., brassy minnow (*Hybognathus hankinsoni*), peamouth, redbelly darter, and threespine stickleback), and introduced fish species (FISS 2014). Only one CRA fish species (i.e., cutthroat trout) has been historically documented in Crescent Slough; however, these observations date back to 1983 (FISS 2014). No salmonids have been detected in the slough since then. Crescent Slough is generally considered to have low values for rearing salmon, especially within reaches close to the Highway 99 ROW (Hemmera 2006). Species captured in upland ditches during field sampling, conducted for the Project, include brassy minnow and threespine stickleback, as well as brown bullhead (*Ameiurus nebulosus*), goldfish (*Carrasius auratus*), and pumpkinseed (*Lepomis gibbosus*).

Fish

Fish species of CRA importance that rely on aquatic habitats throughout the lower Fraser River during different life history stages include Pacific salmon, sturgeon, eulachon, trout, and char. As discussed in **Section 4.4.1**, these species were selected as sub-components to facilitate assessment of potential effects of the Project on fish and fish habitat. Life history requirements, status, and limiting factors for each sub-component are summarized in this section, and described in greater detail in the technical volume, ***Fish and Fish Habitat Study*** included under **Section 16.4**.

Pacific Salmon

Chinook Salmon: Chinook salmon is the largest of the Pacific salmon species that return to the Fraser River and tributaries to spawn. The Fraser River estuary provides important rearing habitats for juvenile chinook. Stream-type chinook, (i.e. fish from the interior Fraser River) generally rear in estuarine habitats with greater marine influence, whereas ocean-type chinook (i.e. ocean-type fish from the Harrison River) occupy tidal channels and brackish marshes of the lower Fraser River, such as the Woodward Island complex and Ladner Marsh just downstream of the Project (Levy and Northcote 1982, Northcote et al. 2007). Adult chinook use the lower Fraser River as a migratory corridor during their return to spawn (DFO 2011). Generally,

stream-type chinook migrate upriver from March to September, while ocean-type chinook migrate upriver from September to November (Fraser et al. 1982). Aboriginal Groups noted that during return migration a natural funnel is created so that fish are held in the lower reaches before they run up river.

Fraser River chinook salmon stocks are not federally or provincially listed.

Chum Salmon: Chum salmon spawn in streams and the lower Fraser River mainstem between Chilliwack and Hope (Ryall et al. 1999). In the Fraser River, chum salmon consist of autumn run stocks that migrate upstream to spawn from September to December, with peak spawning migration occurring in October (Grant and Pestal 2009). The majority of chum salmon spawning habitat is located in Fraser River tributaries downstream of Hell's Gate (near Hope) such as the Harrison, Chehalis, Chilliwack, and Stave rivers (Ryall et al. 1999, Holtby and Ciruna 2008).

Upon emergence, chum fry promptly migrate downstream to the estuary, including the brackish marshes and tidal channels of the lower Fraser River, where they linger as they transition to higher salinity waters (Salo 1991). Chum fry outmigration occurs from February to June, with a peak between mid-March and the end of April (Beacham and Starr 1982, Salo 1991).

Chum salmon stocks of the Fraser River are not federally or provincially listed.

Coho Salmon: Adult coho salmon typically return to spawn in autumn and early winter, and discrete seasonal runs do not generally exist (Holtby and Ciruna 2008). Fry emerge from mid-March to late June and remain in the spawning stream for a year or more (Fraser et al. 1982, Sandercock 1991). Coho smolt outmigration in the Fraser River generally occurs from mid-April to mid-June, with a peak observed in mid-May (Fraser et al. 1982). Coho smolts remain for a few weeks in rearing habitats of Sturgeon and Roberts Banks while adapting to higher salinity conditions. They are scarce in brackish marshes and tidal channels of the lower Fraser River (Fraser et al. 1982).

Coho salmon is not federally or provincially listed; however, the Interior Fraser populations were designated in 2002 as Endangered (COSEWIC 2002). The status of the Interior Fraser coho salmon is anticipated to be re-assessed by COSEWIC and an updated status report is expected to be produced in 2015 (Decker and Irvine 2013). Declines in coho salmon catches in south coastal B.C. have been attributed largely to overharvesting, as well as implementation of conservation measures (e.g., limited exploitation, fisheries closures, non-retention; DFO 2012).

Pink Salmon: Pink salmon have the shortest life cycle of all Pacific salmon, since they always mature as two-year-old fish. In the Fraser River, pink salmon return in odd years. Aboriginal Groups noted that pink salmon populations cycle in two- year periods of relative abundance (i.e., high run years). Spawning is concentrated in tributaries downstream of Hope, but significant spawning also occurs in the Thompson River (Labelle 2009). Spawning migration through the lower Fraser River peaks in late August to early September (Heard 1991).

Outmigration of pink fry occurs from late February through to mid-May (Heard 1991). On average, the time pink fry spend rearing in sloughs and backwater features of the lower Fraser River appears to be negligible (Dunford 1975, Godin 1981, Levy and Northcote 1982).

Pink salmon is numerically the most abundant salmon species in B.C. and is not federally or provincially listed (B.C. CDC 2015).

Sockeye Salmon: Sockeye salmon typically return as four-year-old adults, and populations have characteristic return timings, classified into four groups or runs. Return migrations extend from mid-June through to September (Gable and Cox-Rogers 1993). During consultation on the Project, Aboriginal Groups noted that sockeye salmon populations cycle in four-year periods of relative abundance (i.e., high run years), and that during return migration a natural funnel is created so that fish are held in the lower reaches before they run up river.

Smolt outmigration generally occurs from early April to the end of May (Beamish et al. 2010). One notable exception is the Harrison sockeye stock. Harrison sockeye fry migrate to the estuary shortly after emergence, and rear in Fraser River estuarine habitats, including Deas Slough and Ladner Reach, before entering the Strait of Georgia (Dunford 1975, Levy and Northcote 1981, 1982, Birtwell et al. 1987b). In Deas Slough, sockeye underyearlings have been caught from April to October, with peak abundance from late June to early July (Birtwell et al. 1987b).

Sockeye salmon is not a federally or provincially listed species, however, the Cultus Lake population was designated in 2003 as Endangered (COSEWIC 2003a). On average, sockeye is the most important of the Pacific salmon species in terms of commercial landed value, followed by chinook and chum (DFO 2012). Sockeye salmon is also caught in sport fisheries and in Aboriginal active food drift gillnet fisheries on the lower Fraser River.

Sturgeon

White Sturgeon: White sturgeon, a demersal species resident in the lower Fraser River downstream of Hell's Gate (km 211), are genetically distinct from the rest of the Fraser River system (Nelson et al. 1999, Smith 2002). Spawning occurs during peak freshet (typically from May to July), from the confluence of the Sumas River upstream to the Coquihalla River, with no evidence of spawning in the tidally-influenced river mainstem (Levings and Nelson 2003, Perrin et al. 2003).

Important spring and summer feeding areas for adult sturgeon include the Matsqui Channel and Hatzic Eddy upstream of Mission, as well as the mouth of the Pitt River, and the waters at the Port Mann Bridge, Barnston, Douglas, and Annacis Islands (Glova et al. 2010). During consultation on the Project, Aboriginal Groups noted that adult sturgeon are present seasonally, and identified two main sturgeon staging areas in the lower Fraser River—one in the direct vicinity of the Tunnel and the other in Ladner Reach (Deas Slough, downstream of Canoe Pass). Aboriginal Groups also indicated that sturgeon feed on dead eulachons and herring in April and May, especially within Ladner Reach through to Sea Reach.

During winter, white sturgeon migrate to overwintering areas, where they become sedentary and congregate in densely spaced groups in slow-moving pools as water temperatures drop below 7°C (Neufeld et al. 2010, Ghilarducci and Reeve 2012). Overwintering habitat is widely scattered from Deas Island to the Sumas River confluence, but mainly concentrated in the waters near Annacis Island, the Port Mann Bridge, the mouth of the Pitt and Stave rivers, and Matsqui. Overwintering typically occurs in slow moving water and depths greater than 10 m (Neufeld et al. 2010, Ghilarducci and Reeve 2012).

Juvenile white sturgeon disperse downstream to feed and overwinter, and rear in the lower reaches of tributaries, large backwaters, side-channels, and sloughs throughout the lower Fraser River (Fraser River White Sturgeon Working Group 2005). Rearing of juveniles occurs in tidally-influenced, slow-moving, turbid water, at least five metres deep, over substrates consisting mainly of sand, silt and clay, mixed with gravel (Lane and Rosenau 1995).

In the vicinity of the Project, individual juvenile white sturgeon have been reported from the BC Ferries Fraser Shipyards, immediately downstream of the Project alignment, and in the main channel off Deas Island, immediately upstream of the Project alignment. However, aggregations of up to five overwintering juveniles have also been reported upstream of the Annacis Channel (Glova et al. 2008, 2009). In general, the influence of the salt wedge in estuarine and brackish environments precludes use by smaller juveniles, as the ability of white sturgeon to tolerate brackish and saline waters increases with size (Parsley and Beckman 1994).

Aboriginal Groups have relayed historic declines in numbers of sturgeon in the lower Fraser River. At the federal level, the COSEWIC status of the lower Fraser River white sturgeon population was downgraded in 2012 to Threatened, from the 2003 designation of Endangered (COSEWIC 2003b). Provincially, white sturgeon is Red-listed (B.C. CDC 2015).

Green Sturgeon: Green sturgeon are found in BC along the entire coast (Scott and Crossman 1973). They are rarely observed in freshwater and the extent of freshwater habitat use is unknown. Since 1985, there have been about 15 to 20 reports of green sturgeon in the lower Fraser River, from the river mouth to 90 km upstream. Spawning is known to occur in only three rivers in North America from Oregon to California; there is no evidence that spawning has ever occurred in Canadian rivers (COSEWIC 2004).

Although rare, sub-adult and adult green sturgeon may occur in the Fraser River estuary and lower reaches throughout the year. Habitat requirements in brackish environments are thought to resemble those of white sturgeon (COSEWIC 2004).

At the federal level, COSEWIC re-assessed the status of green sturgeon in 2013 and maintained its designation as species of Special Concern (COSEWIC 2014). Green sturgeon is listed as Special Concern under SARA Schedule 1 (Government of Canada 2006), and is provincially Red-listed (B.C. CDC 2015).

Eulachon

Eulachon return every year to the lower Fraser River to spawn when they are three to four years of age (Cambria Gordon Ltd. 2006). Spawning migration begins in mid-March and continues to mid-May (Hay and McCarter 2000, LGL and Terra Remote Sensing 2009). Within the lower Fraser River, spawning occurs from Deas Island upstream to Mission, however, spawning locations vary considerably among years (Hay and McCarter 2000, Hay et al. 2002).

Historically, most spawning has occurred upstream of New Westminster, and on occasion, in the mouths of large tributaries such as the Pitt River (Hay and McCarter 2000), where the influence of lower salinity water is greater. Due to inter-annual variation in spawning locations, the entire lower Fraser River is considered to contain areas with suitable eulachon spawning habitat (B. Ennevor, Fisheries Resource Manager, DFO, personal communication, January 6, 2014).

Preferred spawning habitat is in areas of relatively slow current (<0.7 m/s), on plateaus or edges composed of stable fine-medium and coarse sand, pebbles, and gravel, in depths of less than seven metres (LGL and Terra Remote Sensing 2009). The river mainstem in the vicinity of the Project is predominantly 12 m deep with no shallow shoals, characterized by unstable sandy substrates subject to annual maintenance dredging. Also considering the low tolerance of eulachon eggs to higher salinity water, the likelihood of suitable eulachon spawning habitat in the Project alignment is greatly reduced. To reach spawning habitat, eulachon transit through areas of relatively slow current (<0.7 m/s) that are 5 to 12 m deep, and have stable sandy

substrates (LGL and Terra Remote Sensing 2009). In the vicinity of the Project alignment, these transit areas likely occur close to the shoreline rather than mid-channel. Immediately after hatching, larvae are flushed seaward (Hay and McCarter 2000).

Eulachon (central Pacific coast and Fraser River populations) was designated as Endangered by COSEWIC in 2011 (COSEWIC 2011), and is provincially Blue-listed (B.C. CDC 2015). The Fraser River and central Pacific coast populations are currently being considered for listing as Endangered under SARA (DFO 2014a). Although historically very abundant, numbers of eulachon returning to the lower Fraser River began declining steadily in the mid-1940s, then exhibited a steeper decline in the 2000s (Moody 2008, Schweigert et al. 2012). During consultation with the Ministry in the context of the Project, Aboriginal Groups cited loss of habitat along with other factors as the cause of these declines, but noted they have also reported that eulachon have been recovering in recent years.

Trout

Coastal Cutthroat Trout: Coastal cutthroat trout inhabit low elevation lakes and rivers along much of the B.C. coast, including streams in the Fraser River basin. They range as far upstream as Hope (160 km inland), and use sloughs and backwaters of the lower Fraser River mainstem, as well as several of its major tributaries (i.e., Pitt, Stave, Harrison, and Chilliwack Rivers and associated lakes) (McPhail 2007, Costello 2008). Sloughs and backwaters provide rearing, overwintering, and migratory habitat for coastal cutthroat trout.

Coastal cutthroat trout are able to spawn multiple times in successive years, usually from late winter to spring, though sea-run populations have also been known to spawn during autumn (McPhail 2007). Depending on the life history form, adults either remain in natal streams, or migrate to lakes or larger river systems to forage before returning to spawn. Sea-run cutthroat migrate to the ocean between March and June (Slaney and Roberts 2005).

Coastal cutthroat trout is provincially Blue-listed (B.C. CDC 2015).

Rainbow/Steelhead Trout: Steelhead trout (*Oncorhynchus mykiss*) is the sea-run form of rainbow trout. Steelhead are found along the entire coast of B.C. in larger streams and rivers, including the Fraser River, that empty directly into the ocean (Hartman and Gill 1968). In the Fraser River, winter-run steelhead enter fresh water in various stages of maturation between November and April (Withler 1966), and spawn by May (McPhail 2007). Summer-run steelhead enter fresh water between May and September as immature fish (Withler 1966), and do not mature and spawn until the following spring, between late March and early May (McPhail 2007). Typically, winter runs are associated with coastal populations and summer runs with inland

populations (Pauley et al. 1986). Steelhead may spawn over multiple years. Some spent spawners migrate to the ocean to feed and may return to their spawning grounds within the same year, or skip a year before spawning again (Levy and Parkinson 2014).

Upon emergence, fry rear in fresh water for one to three years, then migrate to salt water between late April and mid-June, where they feed and grow rapidly before moving out into the open ocean (Quinn 2005). Steelhead use the Fraser River South Arm as a migratory corridor during smolt outmigration and adult spawning migration to natal streams. Resident forms of rainbow trout may also use rearing and overwintering habitats in the Fraser River South Arm.

Rainbow/steelhead trout are not federally or provincially listed.

Char

Dolly Varden: Dolly Varden (*Salvelinus malma*) are associated with cold water streams in most B.C. coastal drainages. Dolly Varden occur as anadromous, migrating between freshwater streams and the ocean; stream-resident, remaining in rivers and streams for most of their life; and lake-run, remaining in a single freshwater body and spawning in adjacent streams. Anadromous Dolly Varden enter the ocean regularly (McPhail 2007).

Spawning occurs in autumn within headwaters of small streams. Upon emergence, juveniles remain in the stream for two to four years (Armstrong 1970). The lower Fraser River is likely used as a migratory corridor by Dolly Varden, due to its proximity to nearshore estuarine and coastal feeding and overwintering grounds. Dolly Varden smolts migrate to the ocean in spring and may remain for only two to four months before returning to fresh water (Armstrong and Morrow 1980). Alternatively, Dolly Varden may remain in marine waters well into the autumn, returning only for spawning or overwintering in freshwater habitats (Bond and Quinn 2013).

Dolly Varden are not federally or provincially listed.

Bull Trout: Bull trout are associated with cold water streams (Dunham et al. 2003). They exhibit variable life histories, including stream resident, lake-run, large river, and sea-run. Anadromous bull trout populations are suspected in the lower Fraser River (McPhail and Baxter 1996, McPhail 2007). Because anadromous char populations occur where bull trout and Dolly Varden overlap, evidence that these char are bull trout rather than Dolly Varden is often circumstantial.

Bull trout spawn in autumn in shallow stream habitats (McPhail and Baxter 1996). Upon emergence in spring, juvenile bull trout rear in spawning streams for at least two years before migrating to larger rivers, or the ocean, depending on the form (Pratt 1992, McPhail and Baxter 1996). The lower Fraser River is likely used as a migratory corridor by bull trout, due to its proximity to nearshore estuarine and coastal feeding and overwintering grounds.

Bull trout is provincially Blue-listed (B.C. CDC 2015), and was designated in 2012 as a species of Special Concern (COSEWIC 2012). Bull trout populations of the B.C. south coast are currently being considered for listing as species of Special Concern under SARA (DFO 2014b).

4.4.3 Potential Effects

This section discusses anticipated interactions of Project components and activities with fish and fish habitat, and the potential effects of such interactions. Information on the mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 4.4.4**. Potential residual effects (i.e., effects remaining following the implementation of mitigation measures) are described in **Section 4.4.5**. A discussion of potential cumulative effects on fish and fish habitat is presented in **Section 4.4.6**.

4.4.3.1 Project Interactions

An overview of potential interactions between Project activities and fish and fish habitat during the construction and operation of Project components is provided in **Appendix A**. A preliminary evaluation of the potential effects of Project interactions on fish and fish habitat, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Construction: Potential interactions of Project-related construction activities with fish and fish habitat include the following:

- Exposure of fish to construction equipment, underwater noise generated by activities such as pile driving and Tunnel decommissioning, and increased suspended sediment and turbidity levels resulting from activities associated with Tunnel decommissioning and other instream or near-shore construction activities.
- Potential disturbance of fish habitat during construction adjacent to water.
- Potential overlap of Project components with small portions of fish habitat along the edges of Deas Slough and Green Slough.
- Potential release of construction area run-off into adjacent waterbodies during highway upgrades.

Operation: Once operational, interactions of the Project with fish and fish habitat are expected to be limited to the following:

- Potential release of stormwater runoff from the new bridge and upgraded highway into the river and sloughs.
- Sedimentation during routine maintenance activities such as vegetation and debris removal, and temporary disruption of natural flows during ditch maintenance.

4.4.3.2 Potential Effects

Potential Effect #1: Physical Injury or Mortality to Fish through Crushing or Entrainment

Crushing or entrainment of fish during Project-related activities can be lethal or sub-lethal, as a result of physical abrasion of the body surface, removal of protective mucous, or physiological stress associated with respiratory obstruction and anoxic conditions. Juvenile and smaller size-class fish are more susceptible to crushing or entrainment than larger fish, due to their limited swimming capability, which may prevent them from avoiding the area of disturbance (Larson and Moehl 1990, McGraw and Armstrong 1990, Reine and Clarke 1998). Because they are associated with bottom substrates, demersal species, such as sturgeon, are more likely to experience adverse effects during dredging (sediment removal) than are pelagic species (Hatin et al. 2007). The potential for crushing or entrainment of fish in the Fraser River South Arm and in upland ditches during Project construction and operation is discussed below.

Fraser River South Arm, Deas Slough and Green Slough

Crushing or entrainment of fish could occur during activities associated with Tunnel decommissioning, including removal of sediment and the protective rock apron and concrete mattress on top of the Tunnel sections.

Crushing or entrainment of salmonid and sturgeon eggs will not occur as these species spawn beyond the RAA boundaries. Eulachon eggs are also unlikely to be crushed or entrained since sediment removal will be conducted in areas where conditions are unsuitable for eulachon spawning (i.e., at a depth of approximately 12 m over a dynamic section of the river with unstable substrates that lack plateaus or stable edges shallower than seven metres, and where the influence of higher salinity water is greater).

Juvenile fish sub-components may be susceptible to crushing or entrainment if present in the Project alignment during sediment removal. Crushing and entrainment during sediment removal does not typically result in the mortality of adult fish because they are highly mobile and able to avoid the area of disturbance.

To the extent that is technically feasible (see **Section 4.4.4**), sediment removal for Tunnel removal is proposed to occur between July 16 and February 28, the least-risk timing window for the protection of juvenile salmon and eulachon (FREMP 2006). Adherence to this timing window will avoid or minimize the potential for crushing and entrainment of these species.

Sturgeon forage and overwinter in the lower Fraser River. Small size classes of juvenile sturgeon may experience physical injury or mortality due to crushing or entrainment if present within the RAA and near the sediment removal site during the least-risk timing windows. The risk of entrainment increases when sediment removal occurs in areas of overwintering aggregations of juvenile sturgeon that are smaller than 19 cm fork length (Boysen and Hoover 2009). Since it is not possible to fully mitigate this effect, it is identified as a potential residual effect and assessed further in **Section 4.4.5**.

Upland Ditches

Construction activities associated with highway improvements that may require works in and around upland ditches will be undertaken in accordance with provincial standards and best practices, including the Ministry's *Standard Specifications for Highway Construction* (B.C. MOTI 2012). Project construction activities that involve instream works will be conducted within prescribed regional least-risk fisheries timing windows⁴ (i.e., July 15 to September 30; Delta 2003, B.C. MOE 2006b) or will use alternative, standard mitigation approaches that protect fish and fish habitat (e.g., work in-the-dry, combined with fish salvages), and will adhere to the provisions of the B.C. *Water Sustainability Act* (where applicable).

The majority of upland ditches within the Project alignment are of relatively low values from a CRA fish habitat perspective (**Section 4.4.2.3**). Further information regarding standard mitigation pertaining to instream works is provided **Section 4.4.4**. After implementation of these mitigation measures, no effects to fish from crushing or entrainment in upland ditches are anticipated, and are not considered further in this assessment.

Potential Effect #2: Physical Injury or Mortality to Fish through Exposure to Underwater Noise during Construction

Exposure to loud, pulsed underwater sound, such as that generated during impact pile driving, can result in:

- Non-auditory effects, such as traumatic injury (i.e., severe tissue or organ damage)
- Auditory effects, such as temporary reduction of hearing sensitivity, thereby compromising the ability of fish to communicate, detect predators or prey, or assess their surroundings

⁴ Prescribed regional least-risk fisheries timing windows encompass Delta's timing window for the protection of salmonids (i.e., August 1 to September 30; Delta 2003), as well as B.C. MFLNRO's timing window for the protection of Pacific salmon (i.e., July 15 to September 15; B.C. MOE 2006b).

Mortality to fish can occur from exposure to peak sound pressure levels (SPL_{peak}) that exceed 30 kilopascal (kPa) (~210 dB re 1 μ Pa) (Vagle 2003, Popper and Hastings 2009). Adult fish are typically more tolerant of underwater noise than juvenile fish of the same species (Halvorsen et al. 2011, 2012, Casper et al. 2012).

Continuous sound, generated from activities such as vessel movement, vibratory piling, and sediment removal, is less intense, and generally insufficient to cause injury or mortality to fish (Michel et al. 2007, Popper and Hastings 2009). Continuous sound, however, has the potential to result in behavioural effects (e.g., habitat avoidance).

For projects that involve loud underwater activities, DFO requires underwater sound monitoring, and deployment of mitigation (e.g., bubble curtain) within one metre from the sound source if underwater sound levels exceed 30 kPa (B.C. MPDCA 2003), or if evidence of impacts to fish is observed.

The U.S. Fisheries Hydroacoustic Working Group (FHWG 2008) has set the following threshold criteria for avoiding injury to fish: 206 dB re 1 μ Pa SPL_{peak} per single strike, or 187 dB re 1 μ Pa²s cumulative sound exposure levels (SEL_{cum}) for fish heavier than or equal to two grams; for fish weighing less than two grams, the SEL_{cum} threshold is 183 dB re 1 μ Pa²s (FHWG 2008). Mitigation is required if a strike is likely to exceed SPL_{peak} or if multiple strikes reach SEL_{cum} (FHWG 2008). Further details regarding threshold criteria for injury to fish are described in **Section 4.3 Underwater Noise**.

Fraser River South Arm, Deas Slough and Green Slough

Potential effects to fish resulting from Project-related underwater noise were assessed by comparing the results from JASCO Applied Science's Marine Operations Noise Model against the FHWG (2008) criteria for fish weighing less than two grams, as well as the BC Marine and Pile Driving Association Contractors (2003) criteria adopted by DFO. Modelled scenarios of Project construction activities are described in **Section 4.3 Underwater Noise**.

Impact pile driving is the only Project-related construction activity that has the potential to generate pulsed underwater noise at levels that, if not mitigated, could injure fish. Underwater noise modelling suggests that, without mitigation, impact pile driving could generate noise at levels that exceed FHWG and DFO SPL_{peak} thresholds within a radius of 53 m and 42 m, respectively (see **Section 4.3 Underwater Noise**).

For 100 minutes of continuous impact piling, the FHWG SEL_{cum} threshold extends to a radius of 602 m for fish with body weight greater than or equal to two grams, and 698 m for fish with body weight less than two grams (see **Section 4.3 Underwater Noise**).

Project siting and design are expected to help prevent or minimize underwater noise-related effects to fish. For example, current Project construction plans call for the piles to be driven either on land or along the edge of Deas Slough to avoid or minimize the need for driving piles through deep water. Underwater noise is expected to be more strongly attenuated in shallow water, restricted by the surrounding slough and river banks, and absorbed by silt and clay sediments. As sediment-borne sound is approximately 20 dB lower than water-borne sound (Zampolli et al. 2013), sound propagating through soil is expected to be sufficiently attenuated before it reaches the water.

Mitigation measures to further minimize adverse effects to fish from underwater noise during Project construction are described in **Section 4.4.4**.

Upland Ditches

Project-related construction activities in upland ditches are not expected to generate underwater noise. Therefore, effects to fish in upland ditches as a result of underwater noise exposure during construction are not considered further in this assessment.

Potential Effect #3: Behavioural Changes due to Increase in Underwater Noise Levels during Construction

In general, fish can be sensitive to changes to the acoustic environment, with species-specific effects depending on fish anatomy and the physical characteristics of the underwater noise. Continuous underwater noise has the potential to result in fish behavioural effects, including alarm response, habitat avoidance, interference with sensory orientation and navigation, and communication masking effects (Knudsen et al. 1997, Fay and Popper 2000). Aboriginal Groups have noted that salmon are sensitive to noise and show changes in behaviour in response to noise.

In the lower Fraser River, fish are continually exposed to ambient noise of low- to moderate-frequency generated predominantly by shipping traffic and intermittently by construction activities. Ambient measurements in the lower Fraser River in the vicinity of the Project exceed 120 dB re 1 μ Pa about 20% of the time, primarily due to larger vessels, such as tugs and container ships, transiting the river. Ambient noise levels in Deas Slough are lower than in the lower Fraser River mainstem, because slough traffic consists primarily of smaller, slow-moving pleasure craft using the marinas. Details on ambient underwater noise levels (i.e., existing conditions) in the vicinity of the Project are provided in **Section 4.3 Underwater Noise**.

Fraser River South Arm

Project construction activities anticipated to generate continuous underwater noise include vibratory pile driving and vibrodensification of native loose soils for the installation of foundations on the edge of Deas Slough and sediment and rip rap removal in preparation for and during Tunnel decommissioning. Underwater noise will also be generated by tugs, which may be operating at the Tunnel crossing during Tunnel removal.

There are no specific behavioural threshold criteria in place for fish exposed to continuous underwater noise; however criteria for marine mammals (see **Section 4.3 Underwater Noise**) is appropriate for reference as a potential disturbance level. As with marine mammals, underwater noise does not have the potential to cause behavioural effects in fish when it falls below background ambient noise levels.

Anthropogenic noise is commonly categorized as pulsed or non-pulsed sounds. Pulsed sounds are brief (less than a few seconds) and intermittent, with rapid changes of sound pressure (e.g., impact-hammer strike, from impact pile-driving). In contrast, non-pulsed sounds are characterized by gradual changes in sound pressure over time (e.g., marine vessels transiting or a vibratory pile driver in operation). Without mitigation, impact-pile driving is expected to result in the highest level of pulsed sound while vibratory pile driving and vibrodensification of native soils are expected to be the most notable sources of non-pulsed sound. Sediment removal and vessel operations are expected to result in minimal change in underwater noise conditions as the noise predicted to be generated by these activities are similar to ambient acoustic levels measured in the lower Fraser River where behavioural disturbance threshold is exceeded 20% of the time (see **Section 4.3 Underwater Noise**). The most notable potential source of changes to ambient noise levels, construction-based noise from impact pile-driving, vibratory pile driving and vibrodensification of native soils are proposed to occur either on land or in shallow water. Given this planned approach, the sound generated by these activities is expected to be sufficiently attenuated before it reaches the receptors so that any potential behavioural effects will be avoided (see **Section 4.4.4** below for a description of proposed mitigation measures and monitoring related to pile driving).

Project operation is not anticipated to involve any activity that could generate underwater noise. Therefore, noise-related behavioural effects on fish during Project operation are not considered further in this assessment

Upland Ditches

No Project-related construction or operation activities are anticipated to generate underwater noise in upland ditches. Therefore, behavioural effects to fish as a result of underwater noise in upland ditches are not considered further in this assessment.

Potential Effect #4: Physical Injury or Mortality due to Exposure to Elevated Levels of Total Suspended Solids

Exposure to elevated TSS levels in the water column can affect fish through:

- Mechanical abrasion and hyper-secretion of mucous, clogging of the gill tissue and consequent respiratory distress caused by lack of the passage of water, and mortality
- Physiological stress leading to reduced growth, reduced feeding rates, and increased susceptibility to invasion by disease-causing parasites

Fish eggs, larvae, and later stages of juvenile fish are typically more sensitive to elevated TSS levels than adults of the same species.

The potential for Project activities to affect fish through elevated TSS levels was determined by comparing TSS concentrations expected to be encountered in plumes generated during Project-related sediment removal activities against B.C. water quality guidelines (WQG) (B.C. MOE 2006a), and the Canadian Council of Ministers of the Environment (CCME) *Water Quality Guidelines for the Protection of Aquatic Life* (CCME 2014) (see **Table 4.4-2**).

Fraser River South Arm, Deas Slough, and Green Slough

Project-related construction activities that may result in elevated TSS levels in the lower Fraser River, Deas Slough, and Green Slough include instream and near-shore construction activities associated with decommissioning the Tunnel and Deas Slough Bridge, realignment of Green Slough to its historic location, and installation of support structures for the new bridge and approaches. Of the proposed instream construction activities, removal of Tunnel segments and overlying sediment and protective cover are anticipated to generate the greatest amounts of re-suspended sediment.

Most fish present in the vicinity of the Project at the start of Tunnel removal activities are likely to disperse out of the immediate area due to elevated noise and physical disturbance associated with the operation. However, fish, especially larval and juvenile stages that remain in or near the sediment plume, could be exposed to elevated TSS levels due to their limited ability to disperse away from a plume.

To prevent or minimize potential Project-related effects to fish from exposure to elevated TSS levels within the Fraser River, mitigation measures will be implemented to maintain TSS levels within the B.C. WQG (B.C. MOE 2006a) and CCME *Water Quality Guidelines for the Protection of Aquatic Life* (CCME 2014) (see **Table 4.4-2**). These include undertaking instream activities between July 16 and February 28 (FREMP 2006) to the extent that is technically feasible and viable, and use of a hydraulic (hopper or cutter) suction dredge where possible to reduce the amount of re-suspended sediment. Sediment suspension during activities associated with Tunnel removal will be of a short temporal nature, and the incremental change in sediment volume is predicted to range from one to nine per cent, which is considered low in comparison with background TSS loads in the lower Fraser River (**Section 4.1 River Hydraulics and River Morphology**). Some CRA fish, in particular sturgeon, are known to use the lower Fraser River outside the least risk timing window. However, turbid conditions often exceeding 50 NTU appear to be favoured by sturgeon, because these conditions provide cover and minimize the risk of predation (Hatfield et al. 2004, Gadowski and Parsley 2005). Also, adult salmon that migrate upriver to natal spawning streams during the least risk timing window have evolved in this highly turbid environment.

Mitigation measures to prevent or minimize potential effects to fish from exposure to elevated TSS levels within Green and Deas sloughs will include undertaking instream works in a manner that provides for maintenance of TSS levels within the B.C. WQG (B.C. MOE 2006a) and CCME *Water Quality Guidelines for the Protection of Aquatic Life* (CCME 2014). As noted previously with respect to Tunnel decommissioning, a key mitigation measure for instream activities will be application of least-risk timing window (July 16 and February 28), to the extent that is technically feasible and viable. Further to the application of seasonal timing to reduce risk to CRA fish, these tidal sloughs extensively dewater during low tides which will facilitate application of additional mitigation measures (e.g., working during low tide when the work site is extensively dewatered, temporary isolation of flow, fish salvage, installation of fill containment berms). Silt curtains can also be deployed within Green and/or Deas sloughs, adjacent to the infill area, if warranted.

Further mitigation measures to minimize physical injury or mortality to fish from exposure to elevated TSS levels during instream Project activities are described in **Section 4.4.4**.

Sediment suspension during activities associated with Tunnel removal will be of a short temporal nature, and the incremental change in sediment volume is predicted to range from one to nine per cent, which is considered low in comparison with background TSS loads in the lower Fraser River (**Section 4.1 River Hydraulics and River Morphology**). Sediment suspension during activities within Green Slough provides for more extensive mitigation, given the tidal

characteristics and separation from the South Arm. As a result, any sediment suspension in Green or Deas sloughs is anticipated to occur within an even shorter timeframe and will result in a more reduced change in background TSS levels than will apply within the South Arm during Tunnel removal.

Some CRA fish, in particular sturgeon, are known to use the lower Fraser River outside the least risk timing window. However, turbid conditions often exceeding 50 NTU appear to be favoured by sturgeon, because these conditions provide cover and minimize the risk of predation (Hatfield et al. 2004, Gadomski and Parsley 2005). Also, adult salmon that migrate upriver to natal spawning streams during the least risk timing window have evolved in this highly turbid environment.

Regardless of the extent of change in TSS levels, it is not possible to fully mitigate sediment suspension effects during either Tunnel removal or partial infilling of Green Slough resulting in identification of a potential residual effect which is assessed further in **Section 4.4.5**.

Upland Ditches

Clearing and grubbing of vegetation along ditches in the LAA for Highway 99 widening and interchange upgrades have the potential to result in localized streamside disturbance, erosion, and sedimentation. In addition, relocation of or modifications to ditches have the potential to result in a temporary increase of TSS levels.

Works proposed in and around upland ditches will be conducted will comply with provincial standards and best practices, adhering to the provisions of the B.C. *Water Sustainability Act* (where applicable) (see **Section 4.4.4**). The majority of upland ditches within the Project alignment are of low value from a CRA fish habitat perspective (**Section 4.4.2.3**). After implementation of these mitigation measures, effects to fish from exposure to elevated TSS levels in upland ditches are not anticipated, and are therefore not considered further in this assessment.

Once operational, highway maintenance activities such as ditch cleaning, clearing, brushing, road maintenance, and repaving of road surfaces have the potential to result in elevated TSS levels within upland ditches.

Maintenance activities will comply with provincial standards and best management practices, adhere to the provisions of the B.C. *Water Sustainability Act* (where applicable), and be undertaken in accordance with the Ministry's *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010). As such, potential adverse effects to fish from exposure to elevated TSS levels in upland ditches during Project operation are not likely to occur and not considered further in this assessment.

Potential Effect #5: Effects of changes in Ambient Water Quality

Changes in habitat quality have the potential to alter the ability of fish to carry out essential life processes such as spawning, rearing, or foraging, increase physiological stress, and result in behavioural changes.

Ambient water quality may be affected during Project-related construction and operation activities that have the potential to induce increased levels of turbidity, re-mobilization of sediment contaminants, and siltation from re-deposition of suspended sediments. Potential effects to fish and fish habitat from changes in ambient water quality are assessed below with reference to baseline conditions as described in **Section 4.2 Surface Water and Sediment Quality**.

Turbid conditions may affect vertical migration of visually-dependent species such as salmon, and induce an alarm reaction, resulting in habitat avoidance. Turbid conditions may also limit light penetration through the water column, restrict prey capture, and reduce the ability of fish to avoid predation.

Conversely, turbid conditions, which may reduce the risk of predation, appear to be favoured by juvenile sturgeon that rear or overwinter in habitats of the river mainstem (Hatfield et al. 2004, Gadomski and Parsley 2005). It has also been suggested that increased turbidity may temporarily increase organic matter in the water column, and cause sturgeon to react positively to the perception of greater food availability (Parsley et al. 2011).

The lower Fraser River is naturally turbid and also subject to annual dredging for maintenance of the navigation channel. Since 1987, ambient water quality has been screened against CCME *Water Quality Guidelines for the Protection of Aquatic Life* (CCME 2014) for parameters including TSS, pH, dissolved oxygen (DO), and metals (e.g., Phippen 2008). On average, objectives have been met 98% of the time and ambient water quality in the South Arm is assessed as good (Phippen 2008).

Concentrations of total aluminum, chromium, and copper exceeding CCME WQG were observed during field sampling conducted for the Project in September 2014 at a mid-channel location upstream of the Tunnel crossing. Total aluminum and chromium concentrations exceeding CCME WQG were also observed at the Deas Slough mouth; although, total chromium concentrations in Deas Slough were lower than those in the South Arm. Petroleum hydrocarbons, oil, and grease were not detected in any water samples.

Arsenic, chromium, and copper in sediment samples collected in September 2014 from the Fraser River mainstem in the vicinity of the Tunnel crossing and Deas Slough consistently exceed *Canadian Sediment Quality Guidelines for the Protection of Aquatic Life* (CCME 1999). Exceedances of Canadian sediment quality guidelines have not been recorded for PCBs.

Fraser River South Arm, Deas Slough, and Green Slough

Project-related construction activities that may result in changes to ambient water quality in the LAA, include sediment removal, removal of the Tunnel and its protective rock apron and concrete mattress. Other activities that involve local disturbance of surficial sediments (e.g., installation of temporary barging facilities, vibrodensification of native soils, pile driving) may also have some potential to affect ambient water quality.

To prevent or minimize potential Project-related changes in ambient water quality, mitigation measures will be implemented to maintain turbidity levels within the B.C. WQG (B.C. MOE 2006a) and CCME *Water Quality Guidelines for the Protection of Aquatic Life* (CCME 2014) (see **Table 4.4-2**). These include undertaking instream activities between July 16 and February 28 (FREMP 2006) to the extent that is technically feasible and viable, and use of a hydraulic suction dredge where possible to reduce the amount of re-suspended sediment.

Some CRA fish, in particular sturgeon, are known to be present within the lower Fraser River throughout the year including the period outside the aforementioned least-risk fisheries timing window of July 16 to February 28. However, turbid conditions appear to be favoured by sturgeon and migrating adult salmon are adapted to inhabit and transit through this highly turbid environment. Therefore, potential effects to habitat quality resulting from changes in ambient water quality are not considered further in this assessment.

Localized disturbance of sediments will occur in Deas and Green sloughs as a result of pile driving and vibrodensification of native soils. As noted above, concentrations of metals greater than those found in the sandy sediments of the Fraser River South Arm in the vicinity of the Project alignment have been documented in the sediments of Deas Slough historically and during field sampling conducted in September 2014. Proposed mitigation measures to limit the dispersion of these sediments during instream works are described in **Section 4.4.4**.

Accidental spills of toxic or hazardous materials (e.g., hydrocarbon fuels, lubricants, concrete), or potential failure of sediment containment measures could result in changes to ambient water quality during Project-related construction activities. Potential changes to ambient water quality resulting from accidents or malfunctions during Project construction are assessed in **Section 8.0 Accidents and Malfunctions**.

Post construction, the increase in impervious surface area associated with the new bridge over the Fraser River South Arm and Deas Slough may result in the discharge of larger volumes of stormwater runoff into these watercourses. Contaminants in stormwater runoff can degrade ambient water quality and may result in toxicity to aquatic life. Mitigation measures to prevent or reduce adverse effects associated with stormwater runoff are described in **Section 4.4.4**. With respect to stormwater runoff, Aboriginal Groups expressed concern for potential project related effects on fish and associated fisheries as a result of highway runoff.

Upland Ditches

Clearing and grubbing along ditches within the LAA in support of Highway 99 widening and interchange upgrades have the potential to result in streamside disturbance, erosion, and sedimentation of the receiving aquatic environment. In addition, relocation or modifications to upland ditch also have the potential to result in changes to ambient water quality.

Construction activities that require works in and around red and dashed-red upland ditches will be conducted, where appropriate, within prescribed regional least-risk fisheries timing windows (i.e., July 15 to September 30; Delta 2003, B.C. MOE 2006b), in isolation of water flows, and with fish salvages as required. In general, instream works that may be required in upland ditches will be undertaken in accordance with provincial standards and best practices, including the Ministry's *Standard Specifications for Highway Construction* (B.C. MOTI 2012), and will comply with the B.C. *Water Sustainability Act*. For more information on standard mitigation pertaining to instream works, refer to **Section 4.4.4**.

After implementation of mitigation, no changes to ambient water quality are expected in upland ditches during instream works. The majority of upland ditches within the Project alignment are of low values from a CRA fish habitat perspective (**Section 4.4.2.3**). Therefore, associated potential adverse effects to fish habitat quality are not considered further in this assessment.

Maintenance activities will comply with provincial standards and best practices, adhere to the provisions of the B.C. *Water Sustainability Act* (where applicable), and be undertaken in accordance with the Ministry's *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010).

Widening of Highway 99 and interchange upgrades are expected to result in an increase of impervious surface area and consequently increased volumes of stormwater runoff that may enter upland ditches. Mitigation measures to prevent or reduce adverse effects associated with stormwater runoff are described in **Section 4.4.4**.

Potential Effect #6: Fish Habitat Alteration

Project-related activities that have the potential to alter fish habitat include: upgrades to existing riprap and new rip rap in the vicinity of the new bridge, removal of the Tunnel, and disturbance or realignment of ditches associated with interchange upgrades, highway widening, and construction of bridge approaches.

Fraser River South Arm, Deas Slough and Green Slough

The new bridge will have a clear span over the Fraser River South Arm. Instream construction activities will be limited to upgrading the existing riprap protection around the base of the bridge support towers. Tunnel removal will be undertaken such that the river banks will be left intact. No excavation and river training works will be required (see **Section 4.1 River Hydraulics and River Morphology**). The extent of fish habitat alteration associated with changes in river hydraulics and morphology as a result of slope armouring upgrades is considered negligible and consequently is not carried forward in the assessment.

Tunnel removal, and associated sediment removal and floating of the Tunnel segments will result in localized scour and sedimentation, as river flow is reduced over the trench left behind after the tunnel segments have been removed. The hydraulic/morphodynamic model (see **Section 4.1 River Hydraulics and River Morphology**) assumes that Tunnel removal will begin in mid-summer during the least-risk timing window, after freshet has receded and turbidity is relatively low, and that any effects will be instantaneous. Since Tunnel removal will actually occur over several months, model results are conservative (i.e., actual effects will likely be of lower magnitude than they would be if the Tunnel removal occurred all at one time).

The incremental change in sediment volume during Tunnel removal is predicted to range from one to nine per cent above ambient, which is considered low compared to existing TSS loads in the lower Fraser River. Elevated TSS may result in a short-term, localized increase in turbidity which will persist during the period in which the disturbance is occurring. Effects from re-deposition of suspended sediment are expected to be minimal.

Therefore, potential fish habitat alteration from sediment suspension and re-deposition in the LAA during Tunnel removal are considered negligible, and potential associated changes in habitat quality in the Fraser River South Arm are not considered further in this assessment.

Operation of the proposed clear-span bridge is not expected to affect river hydraulics and morphology on the Fraser River South Arm. On Deas Slough, where some instream foundations are expected to be located along the water edge, effects related to changes in flow conditions are not anticipated due to the backwater nature of this habitat. Potential associated changes in habitat quality from the new bridge are therefore not considered further in the assessment.

In the Fraser River South Arm, Tunnel removal is not anticipated to result in short-term bank erosion or create barriers to fish migration (**Section 4.1 River Hydraulics and River Morphology**). Predicted changes to river hydraulics and morphology are modest and will occur in a dynamic section of the river that has been previously affected by annual and historic dredging (**Section 4.1 River Hydraulics and River Morphology**), and other manmade disturbances to the river bed such as the downstream Metro Vancouver watermain.

Potential effects on habitat quality associated with decommissioning of the existing Tunnel are considered negligible. Sensitive life stages of salmonids migrating through or foraging in this section of the river tend to occupy the upper water column. As previously noted, eulachon spawning habitat is absent near the Tunnel crossing, while sturgeon overwintering habitat will continue to be present after the trench has naturally infilled. As a result, potential Project-related effects associated with fish habitat alteration are not considered further in the assessment (see **Section 4.4.5**).

Upland Ditches

Proposed highway improvements involving construction activities in and around upland ditches have the potential to alter fish habitat. As described in **Section 4.4.3**, instream works are proposed in or around 15 km (35 %) of total ditch length of dashed-red-, and orange-coded ditches within the LAA.

Most of these instream works will involve relocation of manmade, channelized watercourses (upland ditches), poorly connected to the tidal waters of the lower Fraser River (e.g., located upland of flood control infrastructure, included floodgates and pump stations) and with relatively low values from a CRA fish habitat perspective. Without mitigation, works in and around dashed-red- and orange-coded ditches with the potential to alter fish habitat include, but are not limited to, the following:

- Removal of vegetation cover, potentially resulting in increased water temperatures and decreased food/nutrient inputs
- Temporary flow diversion and ditch realignment, potentially resulting in impairment of ditch connectivity for fish
- Temporary impairment of fish habitat functions within upland ditches, until replacement and/or relocated channels become more mature

Potential encroachment on watercourses and fish habitats, as well as potential environmental effects resulting from ground disturbance and instream works, will be minimized as Project construction is proposed to occur primarily within the existing Highway 99 ROW. Project-related construction in and around ditches will be conducted in accordance with provincial standards and best practices, including the Ministry's *Standard Specifications for Highway Construction* (B.C. MOTI 2012). For more information on standard mitigation pertaining to instream works, refer to **Section 4.4.4**.

Potential effects associated with fish habitat alteration in upland ditches during Project construction are expected to be negligible.

Project activities during operation with the potential to result in fish habitat alteration in upland ditches include highway maintenance activities, such as ditch cleaning, removal of in-channel vegetation, brushing, and clearing.

Instream works will be conducted in accordance with provincial standards and best practices, including the Ministry's *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010) (see **Section 4.4.4**).

Given the low existing values, no potential fish habitat alteration in upland ditches during Project operation is anticipated and resultant changes in habitat quality of these manmade watercourses are not considered further in this assessment.

Potential Effect #7: Changes in Fish Habitat Quantity

Changes in habitat quantity involve the direct loss of fish habitat associated with overlap of Project components with fish habitat. Loss of habitat that supports CRA fish can be expected to meet the definition of serious harm under the *Fisheries Act*. Potentially affected aquatic habitats include highly productive (red-coded) tidal brackish marsh, and intertidal and shallow subtidal channel areas of Deas and Green sloughs. Fish habitat loss has the potential to affect fisheries productivity, because it may result in a measureable reduction in the slough's productive capacity as year-round rearing habitat for CRA fish, including juvenile Pacific salmon.

The new bridge is proposed as a clear span structure over the Fraser River South Arm and without any instream supports; however, there will be a small overlap between bridge/approach support piers and the edges of Deas Slough and Green Slough. The nature and extent of this overlap was determined by overlaying the proposed alignment on the terrestrial ecosystem maps for the assessment area. As shown in **Table 4.4-5**, this exercise indicated that Project alignment overlap with fish habitat is expected to be limited to portions of Deas Slough and Green Slough.

Mitigation measures to minimize the potential loss of fish habitat during Project construction are discussed in **Section 4.4.4**.

Table 4.4-5 Estimated Fish Habitat Losses Associated with Construction of the New Bridge and Approaches

| Structure | Estimated Habitat Loss (m ²) | |
|---------------------------|--|---------------|
| | Instream Area | Riparian Area |
| Deas Slough Piers Total | 2,027 | 2,080 |
| Green Slough Piers Total | 5,707 | 1,654 |
| Total Habitat Loss | 7,734 | 3,734 |

Activities during the Project’s operation phase are not anticipated to result in the permanent loss of fish habitat. As a result, changes in fish habitat quantity during Project operation are not considered further in this assessment.

4.4.4 Mitigation Measures

A hierarchical approach based on the four types of mitigation as outlined below was used in identifying strategies to avoid or minimize potential Project-related effects:

- **Avoidance:** Measures to avoid potential effects on the VC have been/will be incorporated into project considerations such as site and route selection, project scheduling, project design, and construction and operation procedures and practices.
- **Minimization:** Where potential effects on the VC cannot be avoided through project considerations, standard mitigation measures, best management practices (BMPs), and construction and operation environmental management plans (EMPs) will be implemented to minimize potential Project-related effects or reduce them to acceptable levels.
- **Restoration or Habitat Enhancement:** Where potential Project-related effects cannot be avoided or minimized through standard mitigation measures, best practices, or implementation of EMPs, affected components will be restored on-site to pre-Project conditions.
- **Compensation/offset:** Where on-site restoration is not feasible, appropriate means to counteract, or make up for potential Project-related effects on the VC will be identified.

4.4.4.1 Avoidance

The design for the new bridge includes a clear span across the Fraser River South Arm, thereby avoiding instream footprint effects in the river mainstem.

4.4.4.2 Minimization

Selection of measures to minimize unavoidable effects of the Project has been informed by a review of standard industry and BMPs; consideration of mitigation measures and follow-up programs undertaken for past developments by the Ministry; input from regulators, public and Aboriginal Groups; and evaluation of the technical and economic feasibility of proposed measures. Design considerations, standard industry practices and BMPs proposed to avoid or minimize effects on fish and fish habitat described in the following key documents have also informed the development of Project-specific mitigation measures as discussed in this section:

- *Measures to Avoid Causing Harm to Fish and Fish Habitat* (DFO 2013a).
- *Fisheries Productivity Investment Policy: A Proponent's Guide to Offsetting* (DFO 2013b).
- *Environmental Management Strategy for Dredging in the Fraser River Estuary* (FREMP 2006).
- *Dredge Management Guidelines* (FREMP 2005).
- *2012 Standard Specifications for Highway Construction* (B.C. MOTI 2012).
- *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010).
- *Standards and Best Practices for Instream Works* (B.C. MWLAP 2004).
- *Develop with Care 2014: Environmental Guidelines for Urban and Rural Land Development in British Columbia* (B.C. MOE 2014).
- *Best Management Practices for Pile Driving and Related Operations* (B.C. MPDCA 2003).
- *Land Development Guidelines for the Protection of Aquatic Habitat* (Chilibeck et al. 1993).
- *Riparian Restoration Guidelines* (B.C. MOE 2008).
- *Tree Replacement Criteria* (B.C. MELP 1996).

Project Design

Highway 99 improvements are proposed to occur primarily within the existing Highway 99 ROW. Potential encroachment on fish habitat, as well as potential effects resulting from instream works, ground disturbance, clearing, and grubbing of riparian vegetation will be minimized and restricted within the ROW.

Design and construction of the new bridge crossing will conform to standards outlined in the Canadian Highway Bridge Design Code (CHBDC) CAN/CSA S6-06, and the Ministry's Supplement to CHBDC S6-06 *Bridge Standards and Procedures Manual* (B.C. MOTI 2007).

The new bridge design will incorporate stormwater management considerations to mitigate potential effects to fish and fish habitat due to storm runoff-related changes in ambient water quality in the Fraser River South Arm during. This will involve the management and treatment of stormwater runoff from the bridge deck, with stormwater flows diverted away from the river and into stormwater detention ponds.

To prevent or minimize potential effects associated with stormwater runoff during highway operation, roadside ditches will be designed to maintain ambient water quality and pre-development flow regimes. Mitigation measures will include the incorporation of vegetated shoulders and drainage swales, stormwater storage facilities to control runoff rates, headwall structures in culverts, wide bottom ditches, and stormwater management ponds for flood protection.

Best Management Practices and Environmental Management

Environmental protection measures that will be implemented during Project construction and operation to prevent or minimize potential effects on fish and fish habitat will be outlined in a Construction Environmental Management Plan (CEMP) and subsequently in an Operational Environmental Management Plan (OEMP), as described in **Section 12.0 Management Plans**. The CEMP and OEMP will include Fish and Fish Habitat Management Plans that describe mitigation measures to avoid or minimize potential Project-related adverse effects to fish and fish habitat, including physical injury or direct mortality, exposure to underwater noise or elevated TSS levels, and potential changes in fish habitat quality. The plan will comply with best practices, including:

- *Standard Specifications for Highway Construction* (B.C. MOTI 2012).
- *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010).

As described below, the plan will identify regional least-risk timing windows during which Project construction and operation activities with the potential to cause adverse effects to fish and fish habitat can be undertaken. Alternatively, instream work can proceed after implementation of mitigation approaches that protect fish and fish habitat. The plan will also describe the approach and measures to mitigate potential effects from elevated underwater sound and TSS levels.

Timing Windows

To the extent that is technically feasible and viable, sediment removal for Tunnel removal and realignment of Green Slough for bridge support structure construction will be undertaken between July 16 to February 28, the least-risk timing window for the protection of juvenile salmon and eulachon (FREMP 2006). Other CRA fish species can be expected to receive some level of protection from adherence to this instream construction window.

Project construction activities (e.g., site preparation and installation of equipment lay-down areas, highway widening, and interchange upgrades) and Project operation activities (e.g., routine highway and ditch maintenance) involving instream work on upland ditches with CRA fish habitat values will be undertaken during prescribed regional least-risk fisheries timing windows (i.e., July 15 to September 30; Delta 2003, B.C. MOE 2006b), or alternative mitigation approaches will be implemented to protect fish. For example, alternative mitigation may include isolation of flow and pump-arounds, to facilitate work in-the-dry supported by fish (and aquatic life) salvages.

Least-risk timing windows, by their nature, have been developed as standard mitigation measures by regulators (e.g., B.C. FLNR and DFO) to limit activities that involve changes in and around water to periods of least risk. Adherence to the prescribed least-risk timing windows is therefore anticipated to be very effective at minimizing potential effects to fish and fish habitat. Should instream work outside a least-risk timing window be required, the application of alternative mitigation measures as described above is also expected to be effective in protecting fish as well as other aquatic life. The success of adhering to timing windows and/or the application of alternative mitigation measures will be continuously verified through environmental monitoring efforts (see below).

Mitigation of Underwater Noise Effects

Construction activities that have the potential to generate underwater noise will adhere to BMPs and other standard industry practices which set appropriate sound thresholds for the protection of fish. Specifically, *BMPs for Pile Driving and Related Operations* will be adhered to so that underwater noise does not exceed sound levels (i.e., SPL_{peak} 210 dB re 1 μ Pa) that may cause harm to fish (B.C. MPDCA 2003).

Impact pile driving, vibratory pile driving and vibrodensification of native soils during Project construction are anticipated to be the most notable sources of underwater noise (**Section 4.4.3.2**). The potential effects of underwater noise on fish will be avoided or minimized by limiting the occurrence of these activities to land or shallow water along the edge of Deas Slough. For activities that have the potential to generate underwater sound levels in exceedance of thresholds causing physical injury to fish, underwater noise monitoring will be conducted. If considered necessary, additional mitigation measures will be deployed.

As described above, the most effective mitigation measure for avoiding potential effects from underwater noise will be limiting activities with the most notable sources of ambient noise levels to land or shallow water environments. The effectiveness of this mitigation will be confirmed through construction monitoring. If, during a noise-generating activity, a threshold is either exceeded or negative effects to fish in the immediate vicinity of the activity are noted, the activity will cease until additional mitigation measures are implemented.

Mitigation of Effects from Turbidity or Elevated Levels of Total Suspended Solids

Construction activities with the potential to adversely affect fish and fish habitat through increased turbidity and elevated TSS levels will adhere to BMPs and standard industry practices that specify water quality criteria to be met for the protection of fish and fish habitat. To prevent or minimize elevated turbidity and TSS levels associated with Project-related construction activities, mitigation measures will be implemented to maintain levels within the CCME (2002) and B.C. (B.C. MOE 2006a) WQG (see **Table 4.4-2**). Measures that will be implemented to mitigate effects from turbidity or elevated TSS levels in the Fraser River South Arm, and Deas and Green sloughs, as well as provisions for water quality monitoring are described in **Section 4.2 Sediment and Water Quality**. In and around upland ditches, standard industry practices and BMPs that will be adhered to during Project construction activities will include, but will not be limited to:

- Demarcation of vegetation clearing limits on drawings and in the field.
- Delineation (flagging or fencing) in the field of environmentally sensitive no work areas.
- Temporary water diversion, ditch isolation, and fish salvage/relocation to suitable aquatic habitats outside the Project's immediate zone of influence.
- Ditch realignment in accordance with applicable standards and guidelines (e.g., B.C. MWLAP 2004, B.C. MOTI 2012).
- Restoration and revegetation or hydroseeding of cleared areas promptly after use.
- Implementation of a riparian planting design to enhance pre-Project condition, according to applicable riparian restoration guidelines (e.g., B.C. MELP 1996, B.C. MOE 2008).

Erosion and Sediment Control plans within the CEMP and OEMP will describe measures to be followed to avoid or minimize potential physical injury or direct mortality of fish from elevated TSS levels, or changes in fish habitat quality resulting from degradation of ambient water quality due to induced turbidity, and re-mobilization of sediment contaminants. The plans will comply with the *Fisheries Act*, the B.C. *Water Sustainability Act* and associated Water Regulation, provincial standards and best practices, including:

- *Standard Specifications for Highway Construction* (B.C. MOTI 2012).
- *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010).

Erosion and sediment control measures to be implemented during Project construction and operation (bridge and highway maintenance) activities, including works in and around upland ditches will include, but will not be limited to:

- Minimizing the extent and duration of ground disturbance.
- Installing functional erosion and sediment control measures at potentially affected watercourses prior to the onset of Project construction and operation activities.
- Maintaining (repairing or replacing) functional erosion and sediment control measures throughout Project construction and operation (highway maintenance phases).
- Operating construction equipment in-the-dry from the top top-of-bank of watercourses
- Restoration, revegetation or hydroseeding of cleared areas promptly after disturbance, according to applicable riparian restoration guidelines (e.g., B.C. MELP 1996, B.C. MOE 2008).

Erosion prevention and sediment control measures to be implemented in Deas and Green sloughs to control the dispersion of re-suspended sediments generated during ground improvements, pier construction activities, and removal of existing infrastructure may include:

- Developing temporary drainage systems to receive, filter, and direct stormwater and runoff during construction
- Installation of sediment control measures (e.g., turbidity curtains)
- Developing sediment settlement ponds, if required
- Re-stabilization of vegetated areas that are cleared or disturbed during construction
- Careful storage of waste material and soil to prevent possible entry into the aquatic environment

Specific mitigation to be implemented during Tunnel decommissioning to maintain TSS levels within the CCME and B.C. WQG may include such measures as using a hydraulic (hopper or cutter) suction dredge where possible during fill removal to reduce the amount of re-suspended sediment. Removed material is expected to be transported off-site using spoil barge(s) equipped with a sediment containment system (e.g., filter cloth, concrete lock blocks, straw bales).

Environmental Monitoring

The environmental monitoring approach and procedures to be followed during Project construction to evaluate the effectiveness of mitigation measures intended to avoid or minimize potential Project-related adverse effects to fish and fish habitat will be described in the CEMP. The plan will comply with the Ministry's *Standard Specifications for Highway Construction* (B.C. MOTI 2012).

A description of water quality monitoring during Project construction in the Fraser River South Arm and the sloughs, is provided in **Section 4.2 Sediment and Water Quality**.

A description of underwater noise monitoring during Project construction in the Fraser River South Arm and the sloughs, is included in **Section 4.3 Underwater Noise**.

4.4.4.3 Habitat Enhancement

Proposed Project design provides the following opportunities to enhance fish habitat within and adjacent to the Project alignment:

- Restoration of historic Green Slough under the new south approach span into a small embayment on Deas Slough, and creation of 1,700 m² of instream (intertidal and shallow subtidal) habitat and 1,275 m² of riparian habitat.
- Restoration of 125 m² of shallow subtidal fish habitat in Deas Slough, following removal of the existing Deas Slough Bridge instream support piers.

Additional habitat to offset the difference between habitat lost and habitat enhanced will be described in a Fish Habitat Offsetting Plan, as described below.

Habitat enhancement features are generally anticipated to become productive within the first year and become fully productive and viable within 3 to 5 years following restoration. Effectiveness of Project-related habitat enhancement features will be closely monitored and managed through a follow-up monitoring program.

4.4.4.4 Habitat Offsetting

Unavoidable footprint effects of the Project on Deas Slough and Green Slough will be offset through the development of comparable habitat. A Fish Habitat Offsetting Plan will be developed in consultation with regulatory authorities. The offsetting plan will identify on- or near-site offsetting opportunities and outline offsetting implementation methods. Offsetting options described in this plan will be designed to maintain or improve the productivity of CRA fisheries. Offsetting options currently under consideration include:

- Other on- or near-site offsetting opportunities expected to offset any outstanding fish habitat losses, including tidal habitats and adjacent riparian areas of comparable or higher value than the impacted habitat (e.g., construction of intertidal fish habitats on Deas Island within the Highway 99 ROW to provide long-term substantive benefits to CRA fish).

As with habitat enhancement sites, habitat offsetting features are expected to provide some immediate benefits (e.g., construction of new tidal habitat features), and become fully productive and viable within 3 to 5 years. To address the potential risk associated with offsetting habitat(s) not becoming fully functional, effectiveness of these features will be confirmed through a follow-up monitoring program.

Through implementation of a Fish Habitat Offsetting Plan, changes in fish habitat quantity resulting from permanent fish habitat loss will be avoided and are therefore not considered further in this assessment.

4.4.5 Residual Effects and their Significance

After implementation of measures described above, the following potential adverse effects to fish and fish habitat during construction are not expected to be fully mitigated, and are considered further in this assessment:

- Physical injury or mortality to fish from crushing or entrainment
- Physical injury or mortality due to exposure to elevated levels of total suspended solids

Potential residual effects to fish and fish habitat are characterized with respect to the direction, magnitude, extent, duration, frequency, reversibility, and likelihood of each anticipated residual effect. Definitions for ratings applied to residual effects criteria, developed with specific reference to fish and fish habitat are presented in **Table 4.4-6**. Summaries of criteria ratings for the potential residual effects are provided in **Table 4.4-7** (Physical injury or direct mortality to fish from crushing or entrainment) and **Table 4.4-9** (Injury or Mortality due to exposure to elevated levels of total suspended solids). Context, i.e., sensitivity and resilience of fish and fish habitat, based on existing conditions, to changes was also taken into account in characterizing potential Project-related residual effects.

Table 4.4-6 Criteria Used to Characterize Residual Effects on Fish and Fish Habitat

| Criteria | Description | Definition of Rating | |
|-----------|--|----------------------|--|
| Direction | Overall nature of the residual effect | Adverse | Negative effect as a result of the Project. |
| | | Positive | Beneficial effect as a result of the Project. |
| | | Neutral | Neutral effect as a result of the Project. |
| Magnitude | Intensity of the effect relative to natural or baseline conditions | Negligible | No measurable change in fish populations, fish habitat quality or quantity, or contaminant levels. |
| | | Low | A measurable change within the range of natural variability, but not affecting fish population viability. |
| | | Moderate | A measurable change outside the range of natural variability, but not posing a risk to fish population viability. |
| | | High | A measurable change outside the range of natural variability and may affect long-term fish population viability. |
| Extent | Geographic extent / distribution of the residual effect | Site | Effect is restricted to the immediate Project alignment. |
| | | Local | Effect is restricted to the LAA. |
| | | Regional | Effect is restricted to the RAA. |
| Duration | Length of time over which the residual effect is expected to persist | Transient term | Effect occurs once during Project construction or operation. |
| | | Short term | Effect occurs throughout Project construction or operation. |
| | | Moderate term | Effect persists until the first freshet following Project construction or operation before returning to existing conditions. |
| | | Long term | Effect persists beyond the first freshet following Project construction or operation before returning to existing conditions and is unlikely to return to existing conditions. |

| Criteria | Description | Definition of Rating | |
|---------------|---|----------------------|--|
| Frequency | Nature of the occurrence of the residual effect (e.g., how often the stressor affects the VC) | Rare | Effect occurs once during Project construction or operation. |
| | | Uncommon | Effect occurs intermittently during Project construction or operation. |
| | | Frequent | Effect occurs frequently during Project construction or operation. |
| | | Continuous | Effect occurs continuously during Project construction or operation. |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after the disturbance has ceased (or after a period of time after the disturbance has ceased) | Reversible | Baseline conditions will be naturally restored after disturbance has ceased. |
| | | Irreversible | Baseline conditions will not be naturally restored after disturbance has ceased. |
| | | Change | Effect may fluctuate between positive and adverse for the duration of the disturbance. |
| Likelihood | Likelihood that the residual effect may occur | Low | Likelihood of residual effect is less than 25%. |
| | | Moderate | Likelihood of residual effect is between 25% and 75%. |
| | | High | Likelihood of residual effect is greater than 75%. |

Residual Effect #1: Physical Injury or Mortality to Fish from Crushing or Entrainment

Activities associated with Tunnel removal have the potential to result in physical injury or direct mortality of fish, particularly demersal fish species, such as sturgeon. While low, there remains a risk of crushing or entrainment of smaller size classes of juvenile sturgeon in the event that Project-related sediment removal occurs within deep holding areas where sturgeon aggregate. Low numbers (up to five individuals) of juvenile sturgeon are known to aggregate in deep (>10 m) mainstem pools within the Fraser River South Arm. Such features have been identified in Annacis Channel (approximately nine kilometres upstream of the Tunnel) and upstream of the New Westminster trifurcation. Although the river deepens appreciably (>20 m) immediately downstream of the Tunnel along the south bank, holding areas for juvenile sturgeon have not been identified at that location.

The risk may be higher if Project-related sediment removal occurs during the winter months when water temperature drops below 7°C, and juvenile sturgeon become more sedentary within overwintering habitats (Neufeld et al. 2010, Ghilarducci and Reeve 2012). However, residual effects to fish from physical injury are expected to be of low magnitude, to occur only during sediment removal, and to be limited to the immediate vicinity of the sediment removal operations. An overview of the criteria ratings for this residual effect is presented in **Table 4.4-7**.

Context for Characterization Ratings for Residual Effect #1: Project-related sediment removal is proposed to occur in a dynamic section of the river, where maintenance dredging of sections of the navigation channel is conducted on an annual basis. Near-bed water flows are also high at this location, uncharacteristic of low to moderate flow velocities that appear to be more typical of holding and overwintering areas preferred by sturgeon.

Although most fish tend to disperse away from the noise and physical disturbance associated with sediment removal, it is possible that juvenile sturgeon may be entrained if they are unable to swim away from the disturbance. Increased turbidity may also temporarily increase organic matter in the water column and cause sturgeon to perceive greater food availability and swim towards the disturbance. In the lower Fraser River, juvenile white sturgeon as small as 19 cm have been caught upstream of the Annacis Channel and the presence of smaller size classes of sturgeon cannot be precluded from the Fraser River South Arm including the Project alignment (Glova et al. 2008, 2009). As a result, entrainment and loss of a few individual fish may occur during Project-related sediment removal; however, this is not expected to adversely affect overall population integrity.

Fish that do disperse are likely to return to the affected area soon after the disturbance has ceased. Substantial areas of alternative feeding and holding habitat to accommodate any dispersed fish also exist outside of the proposed Project alignment.

Table 4.4-7 Criteria Ratings for Residual Effect #1: Physical Injury or Mortality to Fish Resulting From Crushing or Entrainment

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|---|
| Direction | Adverse | Individual demersal fish that may be present where in-river Project construction activities are occurring may experience physical injury or direct mortality through crushing or entrainment. |
| Magnitude | Low | Change will be within the range of natural variability and is not expected to adversely affect fish population viability. A measureable change is not expected to apply, as only low numbers of individual demersal fish may be directly affected by these construction activities. |
| Extent | Site | Spatial extent will be restricted to the area of disturbance. |
| Duration | Transient term | Effect will occur only during Tunnel removal. |
| Frequency | Rare | Effect will occur only in association with Tunnel removal. |
| Reversibility | Reversible | Affected fish populations are expected to return to baseline conditions. |
| Likelihood | Low | Similar habitat for sturgeon and other demersal species is abundant outside the RAA. Only smaller fish size classes are expected to be at any risk and small numbers are expected to be present during in-river Project construction activities. |

Residual Effect #2: Physical Injury or Mortality to Fish Due to Exposure to Elevated Levels of Total Suspended Solids

Activities associated with Tunnel removal in the Fraser River South Arm and Green Slough realignment have the potential to result in physical injury or direct mortality of fish due to exposure to elevated levels of total suspended solids. Although mitigation measures will be applied to minimize the exposure of fish to elevated TSS levels during these activities, such measures will not completely remove the potential for residual effects on some fish species and life history stages. As the primary mitigation measure, adherence to the least-risk work window of July 16 through February 28 will provide for the substantial avoidance of sensitive life history stages, most notably upstream-migrating adult eulachon and downstream-migrating juvenile Pacific salmon, and eulachon larvae. There are, however, fish present within the river on a year-round basis, and the aforementioned timing window does not provide for avoidance of upstream-migrating adult Pacific salmon or trout and char that are present within a broader timeframe. Although fish populations are well-adapted to the turbid waters of the Fraser River and are often exposed to other sources of elevated TSS levels (both natural and human-sourced), it is recognized that both physical injury and direct mortality can apply in some cases.

Demersal fish species, including sturgeon, are less likely to be adversely affected by elevated TSS levels, given their ecology and physiology. The impact of sediment generation on non-demersal fish during these activities will depend on the ambient suspended sediment concentrations at the time of the works. It is assumed that Tunnel removal will commence in mid-summer and will likely occur after freshet flows have receded, and extend into the winter low-flow period. Suspended sediment volume is predicted to temporarily increase between one per cent and nine per cent over ambient levels during the course of the disturbance. This increase is considered low, given the natural variability of suspended sediment seasonally and annually in the river main channel. Any elevated TSS levels generated during realignment of Green Slough is less likely to be transported and fewer fine sediments would remain in suspension. An overview of the criteria ratings for effects associated with construction-related increase in TSS levels is presented in **Table 4.4-8**.

Context for Characterization Ratings for Residual Effect #2: It is noted that most fish tend to disperse away from impaired water quality, especially when there are opportunities to do so. By avoiding sensitive life history stages (juvenile Pacific salmon and larval eulachon), potential effects of elevated TSS levels will generally be limited to fish that are more active and strong swimmers that can swim away from zones of temporarily impaired water quality. Although it is still possible that physical injury or direct mortality may apply to small numbers of fish, this is not expected to adversely affect overall population integrity. Fish that do disperse are likely to return to the affected area soon after the disturbance has ceased. In addition, substantial areas of alternative migratory, holding, and feeding habitat is present within the wide channel of the Fraser River South Arm to temporarily accommodate any dispersed fish. Similarly, within Green and Deas sloughs there are extensive alternate habitat areas for any dispersed fish that may be present.

Table 4.4-8 Criteria Ratings for Residual Effect #2: Physical Injury or Mortality to Fish Due to Exposure to Elevated Levels of Total Suspended Solids

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|--|
| Direction | Adverse | Individual fish that may be present at, or in close proximity to, in-river or in-slough Project construction activities may experience physical injury or direct mortality due to exposure to elevated levels of total suspended solids. |
| Magnitude | Low | Change will be within the range of natural variability and is not expected to adversely affect fish population viability. A measureable change is not expected to apply, as only low numbers of individual fish may be directly affected by these construction activities. |
| Extent | Site | Spatial extent will be restricted to, or in close proximity to, the area of disturbance. |
| Duration | Transient term | Effect will occur only during Tunnel removal (Fraser River South Arm) and partial infilling activities (Green Slough). |
| Frequency | Rare | Effect will occur only in association with Tunnel removal (Fraser River South Arm) and partial infilling activities (Green Slough). |
| Reversibility | Reversible | Affected fish populations are expected to return to baseline conditions. |
| Likelihood | Low | Similar habitat for potentially affected species is abundant outside the RAA. Only a small subset of CRA fish species and age/size classes are expected to be at risk and only small numbers are expected to be present during in-river and in-slough Project construction activities. |

4.4.5.1 Determination of Significance of Residual Adverse Effects

Significance Definition

A significant adverse residual effect to fish and fish habitat is one that may cause a decline in fish abundance or change in fish distribution to a level at which long-term population integrity is compromised. For a residual adverse effect to be considered significant, re-establishment of the population through natural recruitment (e.g., reproduction or immigration from unaffected areas) would not be expected to occur within a fish species' generation time, after the disturbance has ceased. Fish sub-components that are most susceptible to population effects as a result of the Project are those with longer generation times, such as sturgeon. Fish sub-components with shorter generation times are more likely to re-establish population levels following an adverse effect.

Significance Determination

The significance determination of residual effects to fish and fish habitat is presented in **Table 4.4-9**.

Likelihood characterization was based on professional judgement, with effects defined as those having low, moderate, or high probability of resulting in an adverse residual effect on fish and fish habitat. Low, moderate, or high confidence reflects the level of uncertainty associated with determinations of significance and likelihood.

The residual effect of physical injury or direct mortality of individual fish during Project construction (i.e., from crushing/entrainment or exposure to elevated levels of total suspended solids) is not expected to affect the population integrity of any fish sub-components. Adherence to prescribed least-risk timing windows and implementation of standard industry practices and mitigation measures will limit the extent and magnitude of Project-related effects, and reduce the likelihood of individual fish injury or mortality. As such, the potential residual effects of physical injury or direct mortality are both assessed as not significant. Confidence in the assessment is high due to the localized nature of the effects and the corresponding absence of an anticipated effect on population integrity.

Table 4.4-9 Summary of Determination of Significance of Residual Effects for Fish and Fish Habitat

| Residual Effect | Significance (significant/not significant) | Likelihood (low/moderate/high) | Level of Confidence (low/moderate/high) |
|--|--|--------------------------------|---|
| Residual Effect: Physical injury or mortality due to crushing or entrainment | Not significant | Low | High |
| Residual Effect: Physical injury or mortality due to exposure to elevated levels of total suspended solids | Not significant | Low | High |

4.4.6 Cumulative Effects Assessment

This section describes the assessment of potential cumulative effects associated with residual effects to fish and fish habitat. The combination of the residual Project effects in concert with the effects of other certain and reasonably foreseeable projects and activities comprise the future cumulative effects.

Spatial Boundaries

The spatial boundary of the cumulative effects assessment for fish and fish habitat is defined as the section of the Fraser River South Arm extending from the river mouth to 1,000 m upstream of the Project alignment, and Project alignment plus 500 m on either side of the Project alignment in upland area. The extent of the cumulative effects assessment area coincides with that of the RAA (Table 4.4-3).

Other Certain and Reasonably Foreseeable Projects and Activities

Annual maintenance dredging along sections of the navigation channel within the Fraser River South Arm is the only certain and reasonably foreseeable activity that could interact temporally and spatially with the Project. Maintenance dredging is undertaken annually to maintain adequate depth to accommodate vessel draft (FREMP 2006). Vancouver Fraser Port Authority performs annual maintenance dredging operations in the Fraser River South Arm, which are managed in a way that minimizes adverse effects to fish and fish habitat. Dredging operations adhere to BMPs, including use of suction dredging, avoidance of productive fish habitat areas, and adherence to least-risk timing windows (i.e., July 16 to February 28) for the protection of juvenile salmon and eulachon (FREMP 2006).

Cumulative Interactions and Potential Cumulative Effects

It is assumed that future maintenance dredging operations within the navigation channel of the Fraser River South Arm will continue to be undertaken by Vancouver Fraser Port Authority in a manner that minimizes adverse effects to fish and fish habitat. The potential for an interaction with the effects of the Project resulting in residual effects would depend on the timing and location of the maintenance dredging relative to the Project alignment. It is considered very unlikely that maintenance dredging within the RAA would be scheduled to coincide, spatially or temporally, with the Project's in-river construction activities, including Tunnel removal or partial infilling of Green Slough. Therefore, no cumulative effects to fish and fish habitat are anticipated as a result of an interaction between the Project and future annual maintenance dredging.

4.4.7 Follow-up Strategy

Monitoring will be conducted during and after construction to ensure the mitigation measures identified in **Section 4.4.4** are implemented and expected outcomes in terms of avoiding or minimizing effects on fish and fish habitat are achieved. Broadly, monitoring will include the following:

- Fish habitat monitoring in the vicinity of the Project alignment during construction (including Tunnel removal and decommissioning of any temporary construction-related facilities and post-construction to record any physical habitat changes as a consequence of the Project. During the post-construction period, monitoring will be conducted until the trench has infilled and the riverbed has returned to a stable state. This monitoring will involve ongoing assessment and evaluation of fish habitats located in close proximity to the Project, including fish habitat reference sites within the Fraser River South Arm, Deas Slough and Green Slough.
- Water quality monitoring during Project construction to ensure turbidity levels are maintained below thresholds for the protection of aquatic life.
- Hydrophone monitoring (when applicable) during Project construction activities that have the potential to generate underwater noise to ensure sound levels are maintained below relevant thresholds.

Further follow-up may be undertaken, subject to the results of these monitoring measures and discussion with regulatory agencies.

APPENDIX A

Overview of Potential Project Interactions with Fish and Fish Habitat

Table 1 Overview of Potential Project Interactions with Fish and Fish Habitat

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|--|------------------------|---|--|
| Fish and Fish Habitat | | | |
| Pre-Construction / Site Preparation | | | |
| Pre-Construction / Site Preparation | No interaction | <ul style="list-style-type: none"> • Surveying • Acquiring property for the Project • Relocating utilities | <p>Nature of interaction: No interaction anticipated</p> <p>Rationale: All activities to be land-based</p> |
| | No effect | <ul style="list-style-type: none"> • Conducting additional site investigations (i.e. geotechnical drilling program) | <p>Nature of interaction: Riverbed disturbance associated with additional site investigations (e.g., in the vicinity of the Tunnel)</p> <p>Rationale: Riverbed disturbance expected to be localized with low-volume of re-suspended sediment</p> |
| | Potential Effect | <ul style="list-style-type: none"> • Clearing and grubbing vegetation within the existing Highway 99 ROW • Installing temporary roads, laydown areas, and site offices • Installing temporary bridges and barging facilities • Installing temporary drainage structures and diversions • Preloading for embankment and highway construction • Restoration of Green Slough to its historic alignment | <p>Potential Project-related effects include:</p> <ul style="list-style-type: none"> • Potential decrease in ambient water quality in upland watercourses due to sedimentation during clearing and grubbing, and in the Fraser River and sloughs due to sedimentation during installation of temporary barging facilities • Acoustic effects to fish from noise during ground improvements for new bridge piers (i.e., vibrodensification of native soils) • Accidental spills of deleterious substances (e.g., concrete fines, concrete wash water) (see Section 8.0 Accidents and Malfunctions) |

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|--|------------------------|--|---|
| Construction | | | |
| New bridge including approaches and ramp connections | No interaction | <ul style="list-style-type: none"> • Installing upland piers, including pile installation • Installing retaining walls • Installing drainage structures/settling ponds • Constructing approach spans (concrete deck slab on steel or concrete girder) • Constructing bridge towers and installing support cables using land-based equipment | <p>Nature of interaction: No interaction anticipated Rationale: Proposed activities to include use of precast concrete structures and to be land-based</p> |
| | No effect | <ul style="list-style-type: none"> • N/A | N/A |
| | Potential effect | <ul style="list-style-type: none"> • Realignment of Green Slough • Ground improvements associated with new bridge piers • Installing piers adjacent to Deas Slough and Green Slough, including pile installation • Hoisting pre-assembled deck segments from barges in the river or land-based transport system | <p>Potential Project-related effects include:</p> <ul style="list-style-type: none"> • Physical injury or direct mortality to fish from elevated TSS levels • Physical injury or direct mortality to fish due to auditory injuries from pulsed noise (i.e., impact pile driving) • Changes in fish habitat quality due to acoustic effects to fish from continuous noise (vibratory pile driving, in-river operation of construction vessels, machinery, and equipment), and changes to ambient water quality from sedimentation in the Fraser River and sloughs • Changes to fish habitat quantity due to permanent placement of in-stream piers in Deas and Green sloughs, and partial infilling of Green Slough |

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|---|------------------------|--|--|
| Highway 99 improvements, including interchange upgrades | No interaction | <ul style="list-style-type: none"> • N/A | N/A |
| | No effect | <ul style="list-style-type: none"> • N/A | N/A |
| | Potential effect | <ul style="list-style-type: none"> • Replacement of interchanges at Westminster Highway, Steveston Highway and Highway 17A • Replacement of over/underpasses at Cambie Road, Shell Road, Highway 91 Westbound Ramp, Blundell Road, Ladner Trunk Road and 112th Street • Highway widening from Bridgeport in Richmond to Highway 91 in Delta including construction of embankments, placing and compacting fill for road base, establishing improved drainage and paving | <p>Potential Project-related effects include:</p> <ul style="list-style-type: none"> • Potential changes to ambient water quality due to sedimentation in upland watercourses • Accidental spills of deleterious substances (e.g., concrete debris, asphalt, hydraulic fluids) into upland watercourses (see Section 8.0 Accidents and Malfunctions) |

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|---|------------------------|--|--|
| Tunnel decommissioning | No interaction | <ul style="list-style-type: none"> • N/A | <ul style="list-style-type: none"> • N/A |
| | No effect | <ul style="list-style-type: none"> • N/A | N/A |
| | Potential effect | <ul style="list-style-type: none"> • Removing electrical/mechanical/utilities equipment from the Tunnel • Removing of four Tunnel segments and associated scour protection • Backfilling of onshore portions of Tunnel approaches • Transporting Tunnel elements for offsite recycling and operating support vessels for that activity | <p>Potential Project-related effects include:</p> <ul style="list-style-type: none"> • Physical injury or direct mortality from crushing or entrainment, and elevated TSS levels • Changes in fish habitat quality due to acoustic effects to fish from noise (jetting, mechanical demolition, tug and equipment operation), changes in ambient water quality as a result of induced turbidity, and alteration of fish habitat as a result of riverbed lowering, local scouring |
| Decommissioning of Deas Slough Bridge | No interaction | <ul style="list-style-type: none"> • N/A | N/A |
| | No effect | <ul style="list-style-type: none"> • N/A | N/A |
| | Potential effect | <ul style="list-style-type: none"> • Removal of Deas Slough Bridge including substructures | <p>Potential Project-related effects include:</p> <ul style="list-style-type: none"> • Potential changes to ambient water quality from localized sedimentation during removal of instream concrete piers • Accidental spills of deleterious substances (e.g., concrete debris, asphalt debris, hydraulic fluids) into the river and slough (see Section 8.0 Accidents and Malfunctions) |

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|----------------------------------|------------------------|---|--|
| Operation and Maintenance | | | |
| Highway 99 and interchanges | No interaction | • N/A | N/A |
| | No effect | • N/A | N/A |
| | Potential effect | <ul style="list-style-type: none"> • Operating reconfigured Highway 99 and interchanges. • Highway 99 and interchange maintenance (drainage maintenance, winter maintenance, emergency maintenance, road cleaning, etc.). | Potential Project-related effects include: <ul style="list-style-type: none"> • Changes in ambient water quality resulting from increased stormwater runoff into upland watercoursees due to increase in impervious surface • Alteration of fish habitat due to watercourse maintenance activities, vegetation and debris removal, temporary disruption of natural channel flows • Accidental spills of deleterious substances (e.g., asphalt, hydraulic fluids) into upland watercoursees (see Section 8.0 Accidents and Malfunctions) |
| New bridge | No interaction | • N/A | N/A |
| | No effect | • N/A | N/A |
| | Potential effect | <ul style="list-style-type: none"> • Operating the new bridge. • Bridge maintenance (winter maintenance, emergency maintenance, structure maintenance, etc.). | Potential Project-related effects include: <ul style="list-style-type: none"> • Potential changes in ambient water quality resulting from increased stormwater runoff into the river due to increase in impervious surface • Accidental spills of deleterious substances (e.g., asphalt, hydraulic fluids) into manmade watercourses (see Section 8.0 Accidents and Malfunctions) |

"N/A" indicates that no Project works and/or activities are applicable to the category

4.5 At-risk Amphibian Assessment Highlights:

- The Project is located primarily within the existing, previously disturbed Highway 99 right-of-way, and suitable habitat within the Project alignment is limited.
- At-risk amphibians were not detected within the Project alignment during field studies undertaken in 2014 and 2015. The potential for at-risk amphibians to occur within the Project alignment is low.
- Applying mitigation, including least-risk timing windows, and adherence to standard practices for undertaking in-stream works and highway maintenance activities, will ensure that Project-related effects on at-risk amphibians are addressed.
- No Project-related residual or cumulative effects on at-risk amphibians are expected.

4.5 At-risk Amphibian Assessment

This section presents the results of the assessment of potential effects of the Project on at-risk amphibians, and includes a description of existing conditions, potential Project-related effects and proposed mitigation measures, and an evaluation of residual Project-related and cumulative effects.

4.5.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on at-risk amphibians in terms of Project setting and defines the spatial and temporal assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

No jurisdictional, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects, accessibility constraints, or gaps in data that could limit the ability to predict the effects of the Project were identified; therefore, administrative or technical boundaries do not exist for this VC and are not discussed further.

4.5.1.1 Assessment Context

Amphibians are an important component of aquatic and terrestrial ecosystems and the Lower Mainland region supports a diversity of amphibian species. Areas along the Project alignment, such as Burns Bog in Delta and the Richmond Nature Reserve in Richmond, provide habitat for amphibians. However, previous introduction of two invasive amphibian species and a variety of other stressors, including introduced pathogens and urban, industrial, and agricultural development, have likely contributed to the decline of native amphibian species in this area from historic levels (BC MOE 2014). No long-term trend monitoring is being conducted in the regional assessment area (RAA) and the variety of current projects and activities in the RAA that affect amphibians are not required to monitor and report on their effects. As such, the current ecological trend for amphibians in relation to the effects of other projects is not well understood.

This assessment is focused on the potential effects to at-risk amphibians, these being the ones with potential sensitivity to Project-related effects. In addition to having the potential to interact with and be affected by the Project, at-risk amphibians are of interest to the public, Aboriginal Groups, and/or the government agencies. There are also legally binding requirements that protect certain species and, in some cases, their habitat. Additional information supporting the selection of at-risk amphibians as a VC is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**.

4.5.1.2 Methodology

The assessment of at-risk amphibians follows the general methodology described in **Section 3.0 Assessment Methodology** and applied to all VCs. Building on this approach, the assessment of at-risk amphibians was designed to focus on two specific at-risk amphibian species that have the potential to occur within the Project alignment given the habitat available:

- Northern red-legged frog (*Rana aurora*; Special Concern under SARA Schedule 1, provincially Blue-listed).
- Western toad (*Anaxyrus boreas*; Special Concern under SARA Schedule 1, provincially Blue-listed).

Northern red-legged frog (red-legged frog) have been documented in Richmond, Delta, and Surrey (B.C. CDC 2015), including on the east, north, and west sides of Burns Bog (Delta 2003a). During studies conducted for the Project in 2014, red-legged frog DNA was not found within the Project alignment although it was detected in a roadside ditch approximately 200 m north of the Project, northeast of Highway 91 in Richmond. The species has been selected as representative of the at-risk amphibian VC.

Western toad use aquatic and terrestrial habitat, and return to the same breeding sites each year (Wind and Dupuis 2002). Although suitable habitat is available near the Project alignment (i.e., Burns Bog and Richmond Nature Reserve), western toad has not been documented within the Project alignment. Historic records exist from the Delta Nature Reserve, about 10 km from the Project alignment (Klassen et al. 1971), and from Tilbury Island, approximately four kilometres from the Project alignment (Hemmera 2006). Riparian habitat, in areas likely to be affected by the Project, is primarily grassy roadside verge and shrub-lined ditches abutting agricultural fields, and is of insufficient quality for western toad juvenile rearing. On this basis, western toad is considered unlikely to occur within the Project alignment (Dennis Knopp, pers. comm.) and is not considered further in this assessment.

The Project has the potential to interact with and affect red-legged frog through the loss or disturbance of its breeding or living habitat, or through direct mortality associated with Project construction. Interactions between Project activities and red-legged frog are discussed further in **Section 4.5.3.1**.

The presence of at-risk amphibians, change in area of available habitat, and change in water quality in aquatic habitat were used as indicators to assess trends of at-risk amphibians within the assessment area and evaluate potential Project-related effects. **Table 4.5-1** presents the indicators chosen for the assessment of Project-related effects on red-legged frog, and the rationale for their selection.

Table 4.5-1 Indicators for the At-risk Amphibians

| Indicator | Rationale for Selection |
|---|---|
| Presence of at risk amphibians | Assesses Project-related construction and operations phases' potential mortality to at-risk amphibians. |
| Change in area of available at-risk amphibian habitat | Quantifies Project-related changes in at-risk amphibian habitat availability. |
| Change in water quality in at-risk amphibian habitat | Describes indirect Project-related changes to quality of at-risk amphibian breeding and living habitat. |

4.5.1.3 Assessment Boundaries

The assessment boundaries for at-risk amphibians are defined below.

Spatial Boundaries

The local assessment area (LAA) and RAA for at-risk amphibians are defined in **Table 4.5-2** and shown on **Figure 4.5-1**. The boundaries of the assessment area take into account the scale and spatial extent of potential environmental effects deemed appropriate for red-legged frogs.

Table 4.5-2 Spatial Boundary Definitions for At-risk Amphibians

| Spatial Boundary | Description of Assessment Area |
|--------------------------------|---|
| Local Assessment Area (LAA) | Project alignment. |
| Regional Assessment Area (RAA) | Project alignment plus two km on either side. |

The LAA includes the anticipated Project footprint, where direct effects may occur including the area in which the Project could interact with and potentially have an effect on at-risk amphibians. Consideration was also given to the behaviours and characteristics of at-risk amphibians in the area and their available habitat. The RAA was established to provide a regional context for the assessment of Project-related effects. While the spatial extent of seasonal movements of red-legged frog is not well known (COSEWIC 2004, Maxcy 2004), the maximum distance of their seasonal migration of two kilometres has been chosen as the RAA.

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on at-risk amphibians were established based on the potential for each phase of the Project to interact with and have an effect on at-risk amphibians. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, both the construction and operational phases of the Project include components and activities that could interact with and affect at-risk amphibians present within the Project alignment; therefore, the following temporal boundaries will be assessed:

- Existing conditions
- Project construction (including Tunnel decommissioning)
- Project operation (including maintenance)

Temporal characteristics of the Project phases are discussed in **Section 1.1 Description of the Proposed Project**. Specific temporal considerations for the assessment of at-risk amphibians are discussed in the context of Project interactions and potential effects in **Section 4.5.3**.

Administrative Boundaries

No political, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects on at-risk amphibians have been identified; therefore, no administrative boundaries are defined.

Technical Boundaries

No technical boundaries have been identified that could impose limitations on the assessment of potential Project-related effects on at-risk amphibians.

4.5.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data, and describes the existing conditions of at-risk amphibians within the assessment areas. An overview of the regulatory context for management of at-risk amphibians as relevant to the Project is also provided.

4.5.2.1 Baseline Data Collection

In 2014, the Ministry initiated studies on at-risk amphibians to support Project planning and assessment (**Table 4.5-3**). Building on available information, these studies were designed to address known data gaps.

Table 4.5-3 Desktop and Field Studies Related to At-risk Amphibians

| Study Name | Purpose of Study |
|--------------------------------------|--|
| Desktop literature review | <ul style="list-style-type: none"> • Determine which at-risk amphibians may be present in the LAA. • Identify key data gaps and areas of uncertainty within the LAA. |
| At-risk amphibian habitat assessment | <ul style="list-style-type: none"> • Assess at-risk amphibian habitat in aquatic features (e.g., streams, wetlands, sloughs, and ditches) within the LAA. |
| Environmental DNA (eDNA) sampling | <ul style="list-style-type: none"> • Determine at-risk amphibian presence in the LAA. |

Desktop Literature Review

To determine the potential for presence of at-risk amphibians in the LAA and RAA, an ecosystem-based search of the B.C. Conservation Data Center’s (CDC) online Species and Ecosystems Explorer database (B.C. CDC 2015) was conducted. The results included attributes for at-risk status (i.e., Red- or Blue-listing and inclusion on Schedule 1 of the SARA). The list was then refined by comparing each species’ known geographic range and habitat requirements to the habitat available in the LAA. Information on the potential for presence of at-risk amphibians and their habitat in the Project alignment were compiled from the following sources:

- Species and Ecosystem Explorer (B.C. CDC 2015).
- Species at Risk Public Registry (Government of Canada 2013).
- Committee on the Status of Endangered Wildlife in Canada (COSEWIC; Government of Canada 2014).
- iMapBC (DataBC 2014).
- Delta Watersheds: Fish and Amphibian Distributions Map (Delta 2003a).

- Delta Fish and Amphibians Study: 2000-2003 Sample Site Locations Map (Delta 2002).
- COSEWIC Assessment and Status Report on Western Toad (Wind and Dupuis 2002).
- Accounts and Measures for Identified Wildlife – Red-legged Frog (Maxcy 2004).
- South Fraser Perimeter Road Environmental Assessment Application (Hemmera 2006).

Habitat Assessment and Environmental DNA (eDNA) Sampling

The red-legged frog field studies used: (i) habitat assessments based on known occurrences, (ii) habitat information from the sources above, and (iii) environmental deoxyribonucleic acid (eDNA) analysis of red-legged frog DNA present within the Project alignment aquatic features. All aquatic features (e.g., streams, wetlands, sloughs, and roadside ditches) in the LAA were examined using aerial photographs to identify probable red-legged frog living and breeding habitat for the first stage of the at-risk aquatic amphibians assessment. Field-based assessments of habitat suitability were then conducted in the LAA and eDNA sampling was completed in aquatic features determined to be potentially suitable to support red-legged frog breeding based on:

- Presence of standing fresh water deeper than 0.5 m.
- Permanent or ephemeral status of water feature.
- Presence of emergent vegetation suitable for egg mass attachment.
- Connectivity to other water features having suitable habitat for red-legged frog.
- Proximity to known occurrences of red-legged frog (based on CDC 2015 and the other sources noted above).

Fourteen sites (a site is defined as a discrete lentic aquatic feature) in the LAA had suitable red-legged frog breeding or living habitat at the time of the field assessments, and most were sampled using eDNA methods (**Figure 4.5-1** and **Table 4.5-4**). Environmental DNA is any trace fragment of DNA that is released by an organism into the environment. This method requires collection of water samples from potentially inhabited habitat, with subsequent ex-situ polymerase chain reaction (PCR) analysis of the sample for the presence of red-legged frog and western toad DNA. Reliable detection of aquatic vertebrate species using eDNA, from a variety of freshwater systems, has been confirmed as an effective survey method for amphibians (Ficetola et al. 2008, Goldberg et al. 2011, Thomsen et al. 2012).

At each aquatic feature, one location, and at one site two locations, triplicate water samples were collected using eDNA-specific methods during the red-legged frog breeding season in May 2014 and May 2015. Samples were collected in clean polypropylene bottles and labelled using an indelible marker with the site name, collection time and date, and name of collector. The biologists did not enter the water during sampling in order to prevent contamination from boots and other gear. Biologists wore clean, sterile nitrile gloves to triple rinse the sample bottles with site water, and each bottle was filled with water from the surface of the feature. Immediately after sample collection, a water quality meter was used to collect water chemistry data to facilitate the calculation of detection probabilities. Using a GIS-capable tablet, biologists marked site UTM coordinates and collected water quality data. Water chemistry parameters collected in the field included:

- water temperature (°C)
- pH
- conductivity (mS/cm)
- dissolved oxygen (mg/L)

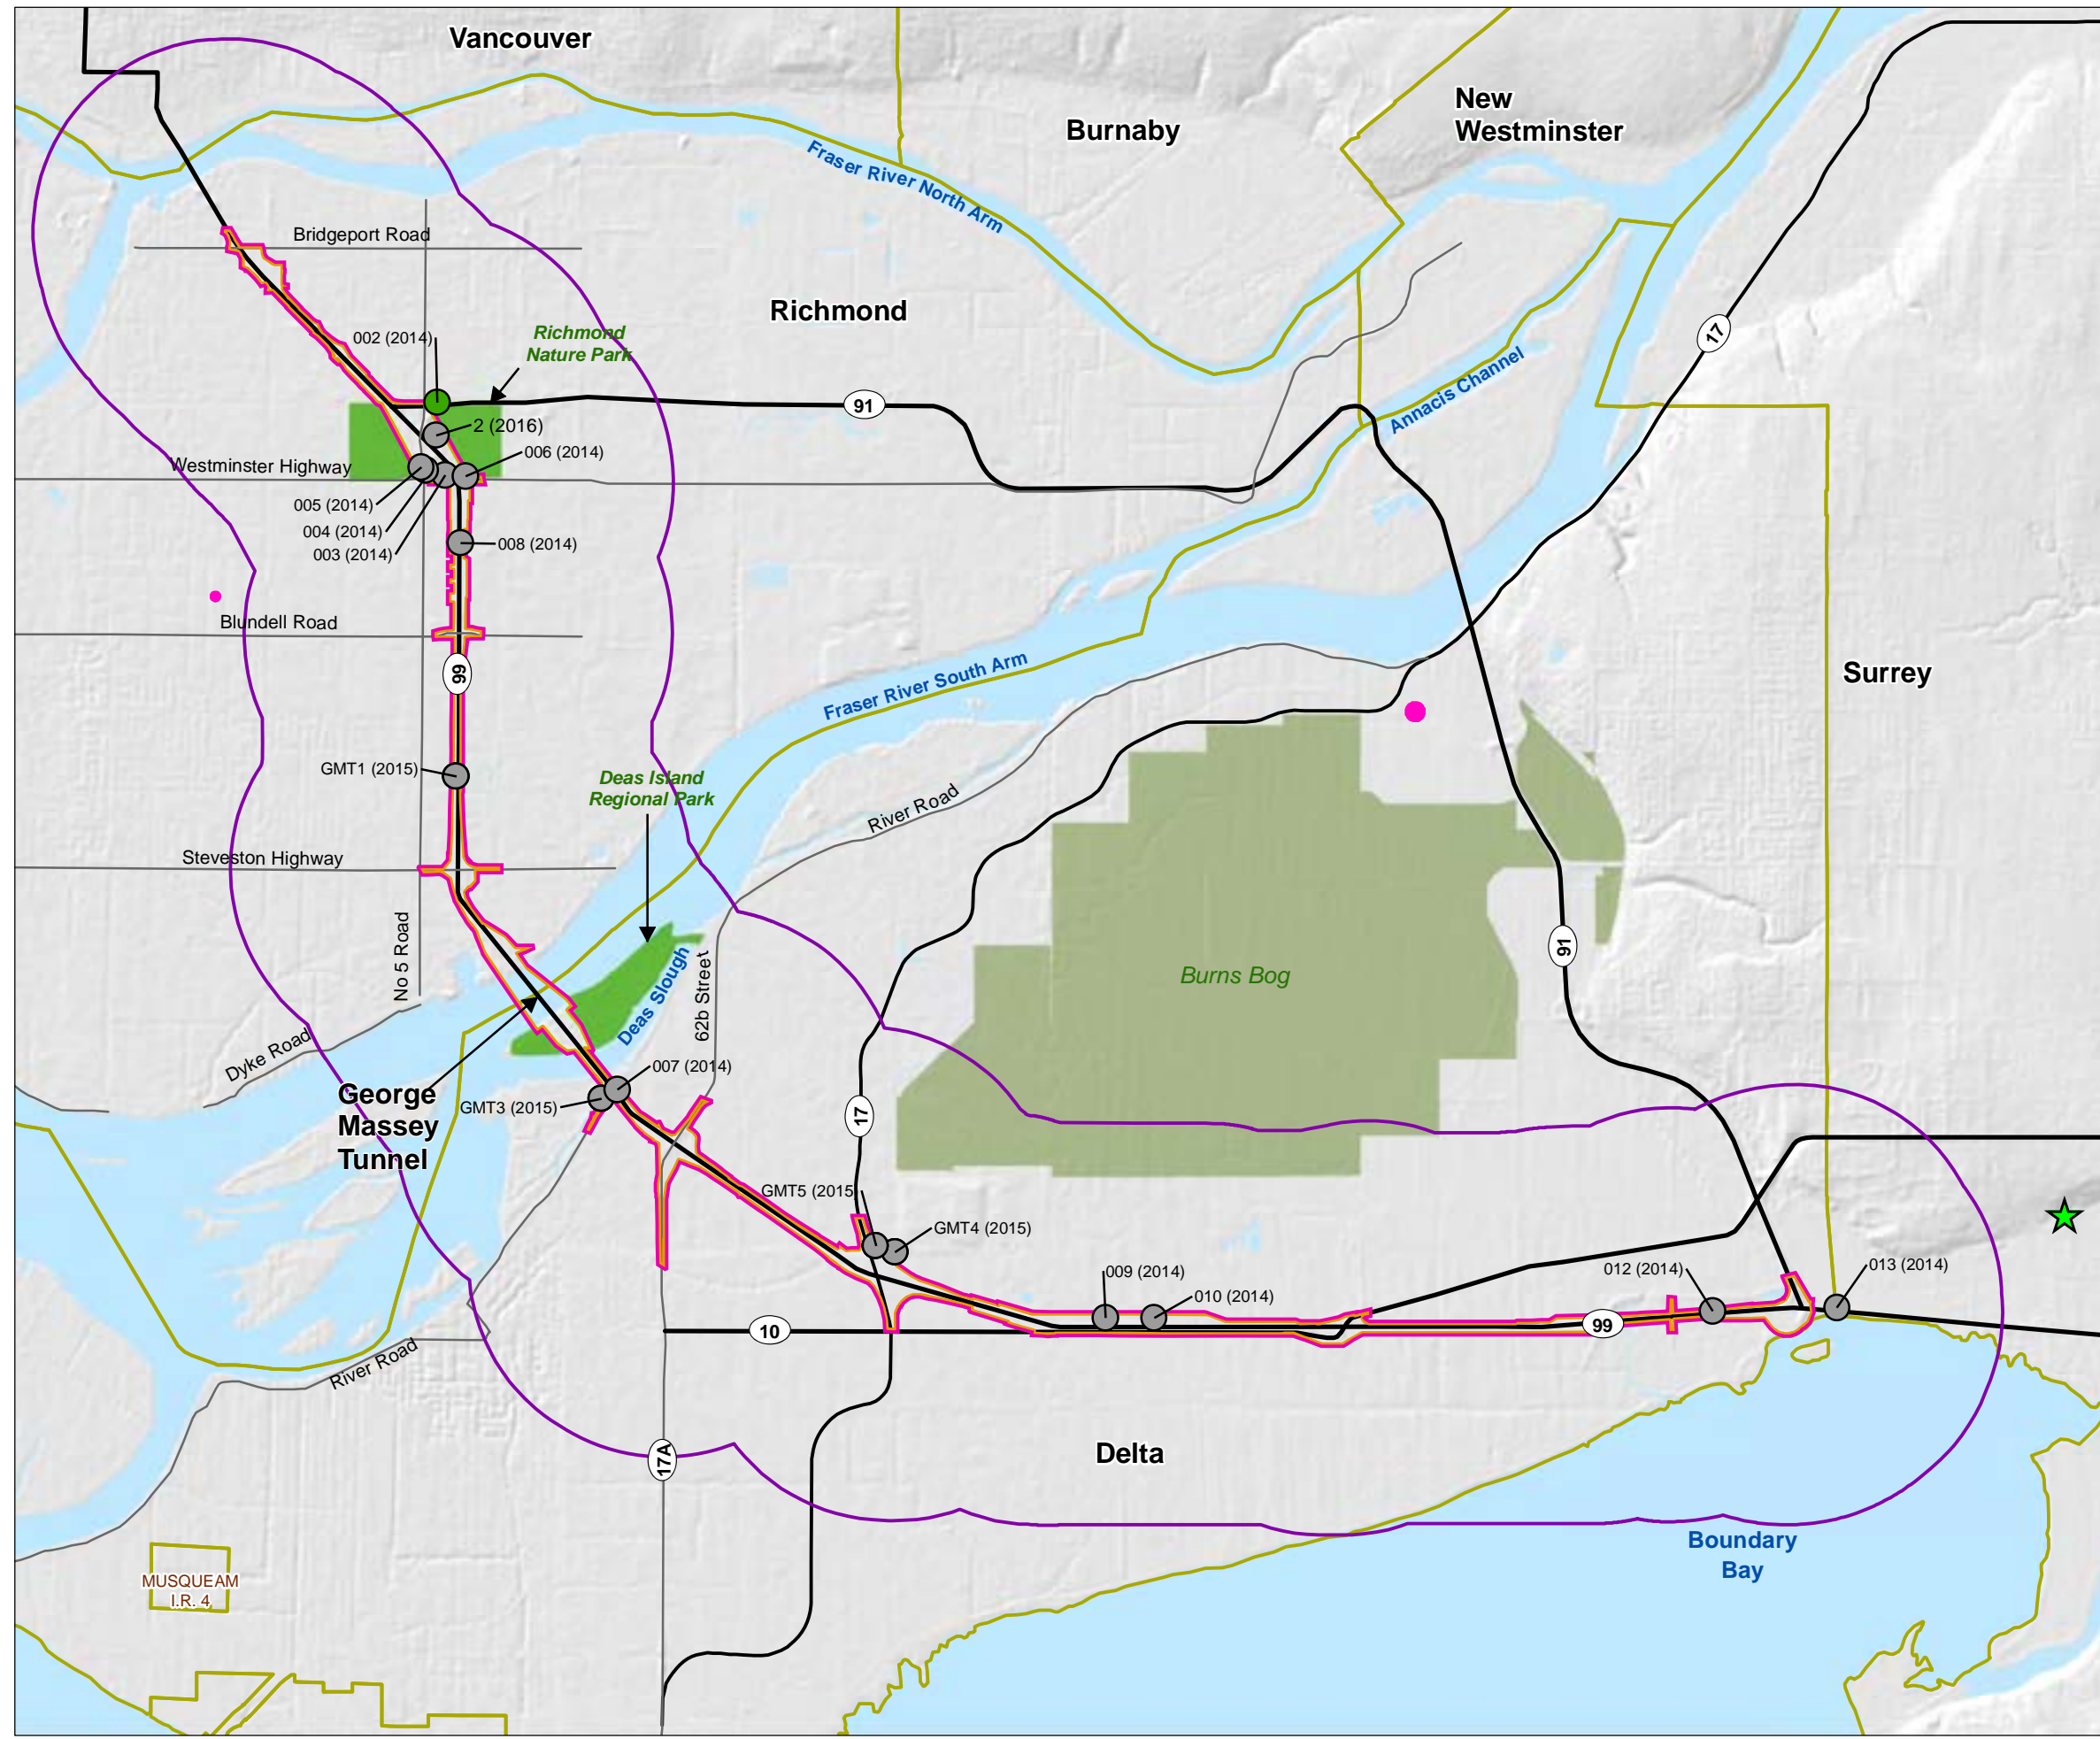

The biologists placed the sample bottles in an insulated cooler with ice packs during fieldwork to prevent DNA degradation prior to off-site filtration and preservation.

Detailed information on the habitat characteristics of the sites is provided in **Appendix A**.

Table 4.5-4 Sample Sites within the LAA with Potentially Suitable Habitat for Red-Legged Frog

| Site # | Description |
|--|---|
| Sites in LAA | |
| GMT1 (2015) | Roadside ditch immediately west of Highway 99 near Mylora Sidaway golf course. |
| 2 (2016) | Ditch beside a disused road west of the Highway 99 to Highway 91 east-bound off-ramp in Richmond. A 300 m-long continuous ditch with mixed conifer hardwood forest on one margin. Permanently wet with emergent wetland vegetation present. |
| 003 (2014) | Roadside ditch with cattails on the west side of Highway 99, just north of Westminster Highway. |
| GMT3 (2015) | Cattail wetland adjacent to Green Slough. |
| 004 (2014) | Roadside ditch with cattails on the east side of No. 5 Road, just north of Westminster Highway. |
| GMT4 (2015) | Roadside ditch with cattails west of 72 nd Street near the Vancouver Landfill entrance. |
| 005 (2014) | Roadside ditch with cattails on the west side of No. 5 Road, just north of Westminster Highway. |
| GMT5 (2015) | Cattail wetland on the north side of Burns Drive east of the South Fraser Perimeter Road near the Vancouver Landfill. |
| 006 (2014) | Roadside ditch with cattails on the east side of Highway 99, just north of Westminster Highway, adjacent to the Richmond Nature Reserve. |
| 007 (2014) | Cattail wetland adjacent to Green Slough. |
| 008 (2014) | Roadside ditch south of Westminster Highway, east of Highway 99. |
| 009 (2014) | Roadside ditch in the flooded cottonwood/red alder – salmonberry forest on the north side of Highway 99 near Highway 17. |
| 010 (2014) | A second sample from the roadside ditch in the flooded cottonwood/red alder – salmonberry forest on the north side of Highway 99 near Highway 17. |
| 012 (2014) | Roadside ditch, on the north side of Highway 99, east of the Highway 91 interchange near Boundary Bay. |
| Sites immediately adjacent to the LAA (and sampled) | |
| 002 (2014) | Roadside ditch with cattails on the west side of Highway 99, just north of Highway 91 in Richmond. |
| 013 (2014) | Ditch south of Colebrook Road. |

AT-RISK AMPHIBIANS
OVERVIEW

| | |
|--------------|------------|
| Figure 4.5-1 | 15/05/2016 |
|--------------|------------|

4.5.2.2 Regulatory Context

Regulation and management of at-risk amphibians in B.C. occur primarily through the following federal and provincial legislation.

Federal

At the federal level, legal protection for at-risk amphibian species is provided under the *Species at Risk Act* (SARA), S.C. 2002, c. 29, which enables management of species at risk to prevent extinction or extirpation from Canada. Under the SARA Section 32(1), it is an offence to kill, harm, harass, capture, or take an individual of a wildlife (including amphibian) species that is listed as Extirpated, Endangered, or Threatened under Schedule 1. The species' residence and critical habitat are also afforded legal protection under Sections 33, 56 and 58(1) of the SARA.

Provincial

The B.C. *Wildlife Act*, R.S.B.C. 1996, c. 488 is the primary provincial legislation protecting wildlife but excluding plants, plant communities, and insects. The Province of B.C., through the B.C. CDC, also assigns species and ecological communities at risk in B.C. to one of three lists (Red, Blue, Yellow) based on provincial Conservation Status Rank. Further explanation regarding the assignment of Conservation Status Rank by the CDC to species and ecosystems at risk is provided in **Section 4.7 Vegetation**.

4.5.2.3 Existing Conditions

Red-legged Frog Habitat

Red-legged frogs require different habitats for breeding and living. They breed in a wide variety of wetlands, including both temporary and permanent ditches, ponds, lakes, and slow-moving streams with emergent vegetation (Maxcy 2004). Living habitat is generally in smaller water bodies in or adjacent to damp forests.

The terrestrial ecosystem mapping (TEM; **Section 4.7 Vegetation**) identified three wetland community types in the LAA, which were evaluated during field studies in 2014 for habitat suitability of red-legged frog. Two of these wetland communities were evaluated during field studies in 2014 to determine their habitat suitability for red-legged frog. These habitats were:

- The cattail marsh adjacent to Green Slough (0.7 ha, TEM polygon 428 [see Section 4.7 Appendix A for TEM mapping figures]).
- The flooded forest on the north side of Highway 99 near the Vancouver Landfill (7.1 ha, TEM polygon 157 [see Section 4.7 Appendix A]).

The remaining identified wetland community, the Lyngbye's sedge salt marsh wetland situated on Deas Island, was not considered to be suitable habitat for at-risk amphibians because of the prevailing saline environment and was therefore not sampled.

Other cattail marsh wetlands were not field-sampled because they either did not appear to support suitable red-legged frog breeding habitat during the sampling period (i.e., TEM polygon 380, a recently constructed highway water detention pond [see **Section 4.7 Appendix A**]), or were on the south side of Highway 99, where the potential for red-legged frog to occur is very low (i.e., TEM polygon 155 [see **Section 4.7 Appendix A**]). The remainder of the aquatic features (i.e., ditches) in the LAA have low potential to support red-legged frog breeding because of poor water quality. Amphibians are sensitive to oxygen availability in aquatic habitats (Govers et al. 2010), and breeding success is partly dependant on levels of dissolved oxygen (Sacerdote and King 2009). Water quality data collected within roadside ditches, as part of the fish and fish habitat baseline study and during the eDNA baseline study, indicate that the majority of the roadside ditches within the Project alignment have levels of dissolved oxygen that fall below the B.C. ambient water quality criteria for dissolved oxygen (B.C. MOE 1997), in both spring and summer sampling periods. As such, the levels of dissolved oxygen in the majority of LAA watercourses are likely prohibitive to at-risk amphibian breeding. Furthermore, habitat in these roadside ditches is unlikely to support at-risk amphibian breeding due to lack of slow flowing, shallow water with emergent vegetation for egg-laying (Storm 1960, Licht 1969, Briggs 1987, Richter and Azous 1995). These ditches also support invasive amphibian species (green frog [*Lithobates clamitans*] and bullfrog [*L. catesbeianus*]), which prey upon native amphibian eggs and out-compete native tadpoles (Kiesecker and Blaustein 1997, COSEWIC 2012).

Pathogens, including Chytridiomycosis (caused by *Batrachochytrium dendrobatidis* (Bd)) and illness caused by rana viruses (family *Iridoviridae*) are infectious amphibian diseases that have been confirmed to cause mortality in amphibians (COSEWIC 2012). Direct evidence of disease-induced amphibian declines has been linked to Chytridiomycosis globally and in B.C. (SPES 2012). Widespread presence of these pathogens is suspected in the LAA and RAA due to the ubiquitous presence of highly mobile non-native amphibians that carry these pathogens (green frog and American bullfrog).

Based on water quality, the roadside ditches in the LAA are unlikely to support at-risk amphibian breeding habitat. They may provide living habitat for red-legged frog, as supported by observations outside the LAA of an adult red-legged frog in a roadside ditch near King George Highway and detection of eDNA from red-legged frog in a roadside ditch in Richmond. This ditch habitat, however, is also considered low quality living habitat.

Red-legged Frog Presence

When applied with strict protocols and validated methods, eDNA provides a highly effective and accepted method to identify presence of target taxa, including red-legged frog, western toad, chytrid and Bd with a high degree of efficacy (Hobbs 2015, Herder et al 2014). Accepted methods were applied during sample collection, to ensure rigour and reliability from the eDNA assessment (Hobbs et al 2015).

From the result of the eDNA sampling, no red-legged frog¹ presence was confirmed in the LAA (Table 4.5-5); specifically, there was no evidence of recent (approximately 7 to 25 days) presence of red-legged frog within the LAA (Strickler et al. 2015) at the time of sampling (Strickler et al. 2015). Since samples were collected during the breeding season in 2014 and 2015, when DNA concentration is expected to be the highest and the likelihood of positive detection is increased (Goldberg et al. 2011), the negative results provide evidence that red-legged frog is not likely to be using wetlands and ditches within the LAA for breeding. These areas could, however, be used as living habitat. Red-legged frog was detected at Site # 002 (2014) (Figure 4.5-1), immediately adjacent to the LAA.

Table 4.5-5 Red-legged Frog Observations in the LAA and RAA

| Site ID | Habitat Type | Red-legged frog detected (Yes/No) | Habitat Present | |
|---------------------|--------------|-----------------------------------|-----------------|----------|
| | | | Breeding | Living |
| Sites in LAA | | | | |
| GMT1 (2015) | Ditch | No | No | Unlikely |
| 003 (2014) | Ditch | No | No | Unlikely |
| GMT3 (2015) | Marsh | No | No | Unlikely |
| 004 (2014) | Ditch | No | No | Unlikely |
| GMT4 (2015) | Ditch | No | No | Unlikely |
| 005 (2014) | Ditch | No | No | Unlikely |
| GMT5 (2015) | Ditch | No | No | Unlikely |
| 006 (2014) | Ditch | No | No | Unlikely |
| 007 (2014) | Marsh | No | No | Possible |
| 008 (2014) | Ditch | No | No | Unlikely |
| 009 (2014) | Marsh | No | No | Possible |

¹ Although the focus of this assessment is red-legged frog, the eDNA study also evaluated the presence of western toad. No western toad presence was identified during this study

| Site ID | Habitat Type | Red-legged frog detected (Yes/No) | Habitat Present | |
|--|--------------|-----------------------------------|-----------------|-----------|
| | | | Breeding | Living |
| 010 (2014) | Marsh | No | No | Possible |
| 012 (2014) | Ditch | No | No | Unlikely |
| 2-2015 (2016) | Ditch | Not sampled | Possible | Possible |
| Sites immediately adjacent to the LAA | | | | |
| 002 (2014) | Ditch | Yes | Unlikely | Confirmed |
| 013 (2014) | Ditch | No | No | Unlikely |

4.5.2.4 Quality and Reliability

The quality and reliability of the data collected and analysed for this analysis is high because it used standard government-approved (e.g., RISC) methods for habitat assessments and peer-reviewed methods for other studies (e.g., eDNA). These methods have been developed for the specific purpose of identifying or establishing trends in amphibians, and in the case of eDNA, are particularly effective for uncommonly occurring at-risk species.

4.5.3 Potential Effects

This section discusses anticipated interactions of Project components and activities with at-risk amphibians, and potential effects of such interactions on red-legged frog. Information on mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 4.5.4**. Potential residual effects (i.e., effects remaining following the implementation of mitigation measures) are described in **Section 4.5.5**. A discussion of potential cumulative effects on at-risk amphibians is presented in **Section 4.5.6**.

4.5.3.1 Project Interactions

An overview of potential interactions between Project activities and at-risk amphibians during the construction and operation of Project components is provided in **Appendix B**. A preliminary evaluation of the potential effects of Project interactions on at-risk amphibians, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Potential effects on at-risk amphibians resulting from Project construction and operation (i.e., maintenance) activities may include direct mortality, disturbance or permanent loss of breeding/living habitat, and introduction of alien invasive species (AIS; e.g. green frog, pathogens). Project-related activities could occur year round, including during the at-risk amphibian breeding season which is a sensitive life period, generally extending from February to October (Calef 1973).

During pre-Application consultation, Aboriginal Groups expressed concern that atmospheric noise from construction activities and traffic could adversely affect wildlife and interfere with frog calls. Changes to noise, light, and visual stimuli resulting in effects on at-risk amphibians are unlikely to occur as a result of the Project and are therefore not considered further in this assessment. As at-risk amphibian breeding habitat was not identified within the LAA, disturbance to breeding activity (calling) as a result of construction is not expected.

Direct highway mortality has been acknowledged as an effect on red-legged frogs (COSEWIC 2004); however, the existing width of, and traffic volumes on, Highway 99 present a formidable barrier to red-legged frog migrations and will continue to do so after the widened highway becomes operational. Direct highway mortality is therefore not considered further.

As previously discussed, no likely at-risk amphibian breeding habitat was identified within the LAA; therefore, consideration of interactions and Project-related effects to at-risk amphibians is limited to the effects related to living habitat.

Fragmentation of at-risk amphibian habitat, and habitat avoidance as a result of sensory disturbance, was not considered a potential interaction given that Highway 99 activities that lead to such potential effects will be the same in the future as they are under existing conditions. The future alignment of Highway 99 with the Project will not change from the existing Highway 99 alignment, resulting in no fragmentation effects as a result of the Project.

Construction: Potential effects on at-risk amphibians as a result of Project-related site preparation and construction activities are as follows:

- Mortality from vegetation grubbing and clearing, and instream construction activities.
- Change in area of available living habitat from disturbance and infilling of upland ditches, as well as instream construction activities in and around roadside ditches.
- Indirect change to living habitat from changes in ambient water quality (e.g., dissolved oxygen) due to an increase in sediment input resulting from road construction activities (e.g., vegetation clearing, temporary drainage de-watering and relocation).
- Indirect change to living habitat from introduction to AIS, including pathogens, green frog, and bull frog, during construction (e.g., transfer of pathogens on equipment or machinery and introduction through relocation of AIS during salvage).

Operation: Potential effects on at-risk amphibians during Project operation may result from routine maintenance activities of the highway and upland ditches. These activities have the potential to cause changes in amphibian living habitat due to vegetation and debris removal, induced turbidity, or temporary disruption of natural channel flows.

Given that the Project is within an existing transportation corridor, and land cover in the LAA is of a disturbed nature (see **Section 4.7 Vegetation**), at-risk amphibian living habitat within these areas is influenced by a combination of direct physical activities and indirect factors such as road runoff. The Ministry has standard operating practices (e.g., B.C. MOTI 2003, B.C. MOTI 2010) to minimize the effects of highway operations and maintenance on adjacent land uses. In addition, aquatic features that do not currently support pathogens, and are therefore sensitive to pathogen transfer effects will be identified during pre-construction eDNA assessment. With these practices in place, Project-related disturbance to at-risk amphibian living habitat during operations and maintenance is anticipated to be negligible. Therefore, the effect is not considered further in this assessment.

4.5.3.2 Potential Effects

Mortality of At-risk Amphibians

Construction Phase

Site preparation activities, including vegetation clearing and grubbing, have the potential to result in direct mortality of at-risk amphibians that may be present in riparian and upland habitats within the Project alignment through crushing by heavy machinery. Because no at-risk amphibians were found within the Project alignment, interactions with vehicles are likely to have a very low probability of occurrence.

Operation Phase

The Project is not anticipated to increase the potential risk of mortality of at-risk amphibians during the operations phase. Existing conditions suggest that there is a low likelihood of at-risk amphibians using living habitat within the Project alignment and the existing risk of mortality is likely to be high given current traffic volume conditions along Highway 99. Traffic volumes in the LAA will increase; however, no measureable change from the existing risk of amphibian mortality is projected. As such, direct amphibian mortality as a result of highway operation will not be considered further in this assessment.

Potential Loss of At-risk Amphibian Living Habitat

Construction Phase

Temporary loss of at-risk amphibian living habitat may occur during instream works including clearing and grubbing of riparian vegetation, temporary de-watering of upland ditches, and installation of temporary drainage structures.

It is anticipated that there will be some overlap between Project components, specifically the support piers for the new bridge and the cattail marsh adjacent to Green Slough (TEM polygon 428 [see **Section 4.7 Appendix A**]), resulting in a potential loss of at-risk amphibian living habitat in this area.

The flooded forest wetland (TEM polygon 157 [see **Section 4.7 Appendix A**]) does not overlap with Project components and, therefore, this site will not be impacted by the Project.

Change in Water Quality in At-risk Amphibian Living Habitat

Construction Phase

Clearing and grubbing of riparian vegetation along ditches, ditch relocation for Highway 99 widening, and interchange upgrades have the potential to result in increased sedimentation and degrade ambient water quality. In addition, inadvertent transfer of AIS and pathogens may occur.

Dissolved oxygen in roadside ditches in the LAA (Sites 003 (2014), 006 (2014), and 008 (2014); **Figure 4.5-1**) and in the flooded forest (sites 9 and 10; **Figure 4.5-1**) are outside the standard *Water Quality Guidelines for the Protection of Aquatic Life* specified by the Canadian Council of Ministers of the Environment (CCME 2014), and are not of a sufficient level to support aquatic life (see **Section 4.2 Sediment and Water Quality**). However, dissolved oxygen levels in the cattail marsh adjacent to Green Slough (TEM polygon 428) meet the *Water Quality Guidelines for the Protection of Aquatic Life* (CCME 2014), and therefore could support living habitat for red-legged frog. Although red-legged frog were not detected during baseline eDNA studies despite repeated sampling (2014 and 2015), mitigation measures to prevent or reduce adverse effects to at-risk amphibians associated with degraded ambient water quality in the cattail marsh are described in **Section 4.5.4**.

Accidental spills of toxic/hazardous materials (e.g., hydrocarbon fuels, lubricants, concrete), as well as potential failure of sediment containment measures, could result in changes to ambient water quality during Project construction activities. Potential changes to ambient water quality resulting from accidents or malfunctions during Project construction are assessed in **Section 8.0 Accidents and Malfunctions**.

Operation Phase

Highway maintenance activities, including ditch cleaning and riparian vegetation maintenance, may induce turbidity within upland ditches and degrade ambient water quality.

Widening of Highway 99 and interchange upgrades are expected to result in an increase of impervious surface area and consequently the rate of stormwater runoff entering the upland ditches will increase. Mitigation measures to prevent or reduce adverse effects associated with stormwater runoff are described in **Section 4.5.4**. It is noted that highway drainage is a small component of the water in the ditches in Richmond where most of the water drains areas outside the highway right-of-way.

4.5.4 Mitigation Measures

Mitigation for the Project has been and will continue to be informed by standard industry practices and best management practices (BMP) including specific amphibian BMP recently developed by the B.C. provincial government, consideration of mitigation measures, and the results of follow up programs undertaken for past Ministry developments; input from regulators, public, and Aboriginal Groups; and evaluation of technical and economic feasibility. Standard industry practices and BMPs proposed to avoid or reduce adverse effects on at-risk amphibians were based on the following key documents:

- *2012 Standard Specifications for Highway Construction* (B.C. MOTI 2012).
- *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010).
- *Standards and Best Practices for Instream Works* (B.C. MWLAP 2004).
- *Develop with Care 2014: Guideline for Amphibian and Reptile Conservation during Urban and Rural Land Development in British Columbia* (B.C. MOE 2014).
- *DRAFT Best Management Practices for Amphibian and Reptile Salvages in British Columbia* (Wind et al. 2013).
- *Riparian Restoration Guidelines* (B.C. MOE 2008).
- *Tree Replacement Criteria* (B.C. MELP 1996).
- *National Guide to Erosion and Sediment Control on Roadway Projects* (TAC 2005).

A hierarchical approach based on the four types of mitigation as outlined below, was used in identifying strategies to avoid or minimize potential Project-related effects:

- **Avoidance:** Measures to avoid potential effects on the VC have been/will be incorporated into Project considerations such as site and route selection, project scheduling, project design, and construction and operation procedures and practices.
- **Minimization:** Where potential effects on the VC cannot be avoided through project considerations, standard mitigation measures, BMPs, and construction and operation environmental management plans (EMPs) will be implemented to minimize potential Project-related effects or reduce them to acceptable levels.

- Restoration or Habitat Enhancement: Where potential Project-related effects cannot be avoided or minimized through standard mitigation measures, best practices, or implementation of EMPs, affected components will be restored on site to pre-Project conditions.
- Compensation/offset: Where on-site restoration is not feasible, appropriate means to counteract, or make up for potential Project-related effects on the VC will be identified.

Proposed mitigation measures to avoid or minimize adverse Project-related effects on at-risk amphibians are summarized in **Table 4.5-6**.

4.5.4.1 Avoidance

The Project has been designed to be located largely within the existing Highway 99 Right-of-Way (ROW), in areas that have been previously disturbed and contain minimal natural vegetation, thereby avoiding potential overlap with at-risk amphibians. As such potential encroachment on at-risk amphibian living habitat, as well as potential temporary loss of at-risk amphibian habitat resulting from instream works, ground disturbance, clearing, and grubbing of riparian vegetation during Project construction will be minimized and restricted to within this ROW.

As described in **Section 4.4 Fish and Fish Habitat**, upland ditches will be designed to maintain ambient water quality and pre-development flow regimes to avoid or minimize potential Project-related changes to ambient water quality as a result of highway stormwater runoff during Project operation.

4.5.4.2 Minimization

Project Design

Engineering considerations indicate that an overlap between the proposed bridge support piers and the cattail marsh adjacent to Green Slough (TEM polygon 428) cannot be avoided; however, through Project design, this unavoidable overlap will be minimized and will not affect the functionality of the ecosystem. This will minimize the extent of potential at-risk amphibian living habitat.

Effects of Project construction on the recently-established cattail marsh in the Highway 17 interchange (TEM polygon 380) will be minimized during design to reduce the ground disturbance.

Best Management Practices and Environmental Management

Environmental protection measures that will be implemented during Project construction and operation to prevent or minimize potential effects on at-risk amphibians will be outlined in a Construction Environmental Management Plan (CEMP), and subsequently in an Operational Environmental Management Plan (OEMP), as described in **Section 12.0 Management Plans**. The CEMP will include a Fish and Fish Habitat Management Plan, Erosion and Sediment Control Plan, and Terrestrial Vegetation and Wildlife Management Plan. These component plans will describe standard best practices and Project-specific mitigation measures and will effectively prevent or minimize potential adverse effects on at-risk amphibians that might otherwise result from the Project during construction. Key elements of these plans are discussed below.

Mitigation Measure #1: Fish and Fish Habitat Management Plan

Mitigation proposed to avoid or minimize potential Project-related adverse effects on fish and fish habitat will also benefit at-risk amphibians. Relevant provisions from the Fish and Fish Habitat Management Plan (e.g., mitigation for upland ditches) will be implemented and are anticipated to mitigate effects to at-risk amphibian habitat related to changes in ambient water quality.

As described in **Section 4.4 Fish and Fish Habitat Assessment**, Project construction and operation activities that involve instream works will be conducted in accordance with provincial standards and best practices, including the Ministry's *Standard Specifications for Highway Construction* (B.C. MOTI 2012) and the Ministry's *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010), respectively. Also with consideration of low likelihood of at-risk amphibians to be present in upland ditches within the Project alignment, the potential for at-risk amphibian mortality during Project-related instream works is greatly reduced.

Upon completion of instream works associated with Project construction activities, channel flows will be re-established, and riparian vegetation will be restored through hydro-seeding and re-planting to pre-disturbance conditions or better. Therefore, riparian habitat quality in ditches relative to existing conditions will be maintained or improved.

Mitigation Measure #2: Erosion and Sediment Control

Erosion and sediment control measures to be included in the Erosion and Sediment Control Plan are presented in **Section 4.4 Fish and Fish Habitat**. They generally include installing and maintaining erosion and sediment control measures at potentially affected watercourses prior to the onset of Project construction and operation, operating machinery and equipment in-the-dry from the top-of-bank of watercourses, and restoring cleared areas promptly after use.

Mitigation Measure #3: Terrestrial Vegetation and Wildlife Management

A Terrestrial Vegetation and Wildlife Management Plan will be developed as part of the CEMP to avoid or mitigate potential effects to vegetation and wildlife (including at-risk amphibians) during Project construction. The plan will describe procedures for amphibian salvage and translocation, as well as mitigation approaches to minimize ground disturbance.

Project-related instream works will be conducted within prescribed regional least-risk fisheries timing windows (i.e., July 15 to September 30; Delta 2003*b*, B.C. MOE 2006) or with alternative mitigation approaches (e.g., work in-the-dry, combined with amphibian salvages) to avoid effects to water quality during sensitive amphibian breeding life stages. All maintenance activities will adhere to the provisions of the B.C. *Water Act* (where applicable) and be undertaken in accordance with provincial standards and best practices, including the Ministry's *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010).

Amphibian Salvage and Translocation

As part of pre-construction activities, amphibian salvage and translocation will be conducted to avoid or minimize potential Project-related mortality to native amphibians from instream works during Project construction. Salvage and translocation will comply with the B.C. *Wildlife Act* and pertinent permits, and will be undertaken in accordance with the DRAFT *Best Management Practices for Amphibian and Reptile Salvages in BC* (Wind et al. 2013). Salvage areas and suitable translocation habitat will be identified, and sites where salvage is conducted and amphibians are transported, will be pre-tested for pathogens to avoid the transport and introduction of AIS (i.e. green frog) to new aquatic features.

Mitigation to Minimize Ground Disturbance

Project footprint disturbance will be minimized by flagging construction boundaries in the field and marking clearing perimeters to minimize the potential for accidental encroachment on forested areas and wetlands that may be suitable living habitat for at-risk amphibians.

Disturbance to the cattail marsh adjacent to Green Slough, which has potential to support at-risk amphibian living habitat, will be minimized by:

- Limiting heavy machinery access points from River Road South to prevent substrate compaction.
- Placing site infrastructure as close as possible to the existing road verges during detailed design to minimize the need for clearing in the wetland.
- Storing machinery and construction materials outside of the wetland.

4.5.4.3 Habitat enhancement

As discussed under mitigation of Project-related effects on vegetation, the following measures are proposed to improve the functionality of the highly disturbed cattail marsh adjacent to Green Slough (TEM polygon 428), which overlaps with the Project:

- Removal of invasive species and garbage from the marsh and revegetation using native species as appropriate to improve habitat quality in the area surrounding the new bridge support piers.
- Installation of an appropriate stormwater management system for the upgraded highway and the new bridge to avoid potential introduction of contaminants into the ecosystem through road runoff.

The above measures are expected to improve the quality and viability of the ecosystem within TEM polygon 428, and counteract potential effects of the loss of amphibian habitat due to the proposed installation of new bridge piers.

4.5.4.4 Habitat Offsetting

Mitigation Measure #4: Offsetting of Effects to Cattail Marsh near River Road South

As described in **Section 4.7 Vegetation**, unavoidable Project footprint effects on the cattail marsh near Green Slough (River Road South) will be offset through the creation of a cattail marsh within a biofiltration pond near the existing south portal of the Tunnel. This habitat will be subject to monitoring during and after construction to ensure that it is functioning as intended. The establishment of the cattail marsh, which has the potential to provide suitable living habitat for at-risk amphibians, is expected to offset the partial loss of marsh area within TEM polygon 428.

Table 4.5-6 Summary of Mitigation Measures to Address Potential Adverse Project Effects on At-risk Amphibians

| Potential Effect | Mitigation Measure |
|--|--|
| Construction Phase | |
| Direct mortality of at-risk amphibians from instream works | <ul style="list-style-type: none"> • <i>Mitigation measure #3</i>: Salvage and translocate at-risk amphibians to nearby suitable habitat. |
| Loss of at-risk amphibian living habitat | <ul style="list-style-type: none"> • Project siting and design • <i>Mitigation measure #1</i>: <ul style="list-style-type: none"> ▫ Undertake instream works in accordance with standards and best practices, including the Ministry's <i>Standard Specifications for Highway Construction</i> (B.C. MOTI 2012). ▫ Restore riparian vegetation to pre-disturbance conditions or better. • <i>Mitigation measure #3</i>: Minimize ground disturbance to avoid sensitive habitats, including the cattail marsh adjacent to Green Slough. • <i>Mitigation measure #4</i>: Habitat offsetting of the cattail marsh near Green Slough with creation of new approach near south portal. |
| Changes to water quality in at-risk amphibian living habitat | <ul style="list-style-type: none"> • <i>Mitigation measure #1</i>: Undertake instream works in accordance with standards and best practices, including <i>Standard Specifications for Highway Construction</i> (B.C. MOTI 2012). • <i>Mitigation measure #2</i>: Install and maintain functional erosion and sediment controls. • <i>Mitigation measure #3</i>: prior to construction, test for presence of pathogens at aquatic features with potential exposure to machinery or equipment. |

| Loss of at-risk amphibian living habitat | <ul style="list-style-type: none"> • <i>Mitigation measure #1</i>: Undertake instream works in accordance with the Ministry's <i>Environmental Best Practices for Highway Maintenance Activities</i> (B.C. MOTI 2010). |
| Changes to water quality in at-risk amphibian living habitat | <ul style="list-style-type: none"> • Project siting and design: Design ditches to maintain ambient water quality and pre-development flow regimes. • <i>Mitigation measure #1</i>: Undertake instream works in accordance with standards and best practices, including the Ministry's <i>Environmental Best Practices for Highway Maintenance Activities</i> (B.C. MOTI 2010). |

4.5.5 Residual Effects and their Significance

4.5.5.1 Characterization of Residual Effects

Residual effects are those adverse effects that remain following implementation of mitigation measures. All potential Project-related effects on at-risk amphibians are expected to be addressed through mitigation measures, resulting in no residual effects. Implementation of mitigation measures described in **Section 4.5.4** is anticipated to address potential effects related to physical injury or mortality, change in habitat availability and quality, or introduction of AIS of at-risk amphibians. Avoidance mitigation is expected to be immediately effective in protecting at-risk amphibians from habitat loss and direct mortality. Minimization mitigation is expected to be immediately effective or effective immediately following the proposed restoration and enhancement of disturbed areas. These are standard mitigation measures that the Ministry has used on other project within the lower mainland with proven success.

4.5.5.2 Confidence and Risk

The confidence with this characterization of residual effects and its predictions is high.

A number of factors were considered in reaching this conclusion including:

- (i) The quality and reliability of the data that supported the assessment. Standard sampling methods, reliable methods published in government or peer-reviewed documents were used.
- (ii) The availability of data for the area surrounding the LAA (including in the RAA) is reasonable, in large part from MoTI studies on the nearby South Fraser Perimeter Road and the Environmental Assessment Office-sponsored amphibian work in Burns Bog (Fraker et al. 1999).
- (iii) The experience in identifying and managing effects on at-risk amphibians from the nearby MoTI South Fraser Perimeter Road gives high confidence in the likelihood of effects and the means by which they should be managed.
- (iv) The use of standard BMPs or MoTI-prescribed policies for avoiding or minimizing Project-related effects on at-risk amphibians, including pre-construction assessment of pathogens, minimizing construction-related disturbance to aquatic features in the Project area, avoiding construction-related disturbance to identified Environmentally Sensitive Areas (ESA) and invasive species (and pathogen) management to minimize transfer between sites.

No further risk assessment is considered necessary as the mitigation measures proposed address effects and uncertainty.

4.5.6 Cumulative Effects and their Significance

As discussed in **Section 4.5.5**, the Project is not likely to have any residual effect on at-risk amphibians. Therefore, a cumulative effects assessment was not necessary.

4.5.7 Follow-up Strategy

The potential for at-risk amphibians to occur within the Project alignment is low. During construction, implementation of the CEMP is expected to effectively prevent or minimize potential adverse effects on at-risk amphibians that might otherwise result from the Project during construction.

As described above, the creation of a cattail marsh within a biofiltration pond near the existing south portal of the Tunnel proposed to offset effects on the existing cattail marsh near Green Slough has the potential to provide suitable habitat for at-risk amphibians. As part of the vegetation follow-up program, this habitat will be subject to monitoring during and after construction to ensure that it is functioning as intended.

"N/A" indicates that no Project works and/or activities are applicable to the category

4.6 Marine Mammals Assessment Highlights:

- Marine mammals, specifically harbour seals and sea lions, are known to use marine areas within the Project alignment. Other species of conservation interest, including southern resident killer whales, do not occur in the Fraser River.
- Underwater noise during construction is the key area of focus for potential Project-related effects on marine mammals.
- Underwater noise in the Fraser River South Arm from existing sources currently exceed thresholds for disturbance to marine mammals approximately 20% of the time.
- The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.
- Standard industry and best management practices will be applied to activities such as impact pile driving that have the potential to generate underwater noise to ensure sound thresholds for the protection of marine mammals are adhered to.
- No Project-related residual or cumulative effects on marine mammals are expected.

4.6 Marine Mammals Assessment

This section presents the results of the assessment of potential Project effects on marine mammals and includes the rationale for selecting marine mammals as a valued component (VC), identification of Project-related effects, proposed approaches to mitigation, and evaluation of residual Project-related and cumulative effects.

4.6.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on marine mammals in terms of Project setting, and defines the spatial, temporal, administrative and technical assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

No jurisdictional, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects, accessibility constraints, or gaps in data that could limit the ability to predict the effects of the Project were identified; therefore, administrative or technical boundaries are not considered relevant.

4.6.1.1 Assessment Context

The Project is located in close proximity to the Strait of Georgia which supports a number of marine mammals, including toothed whales, baleen whales, seals, sea lions, and sea otters. In the Strait of Georgia, marine mammals are the focus of a substantial wildlife viewing and ecotourism industry and are of cultural importance to Aboriginal Groups and the public.

Within the lower Fraser River and the Project alignment, only seals, particularly harbour seals and sea lions, are likely to occur, and their presence is seasonal.

Aboriginal Groups have reported that areas within the wider Fraser River estuary were utilized by Hul'q'umi'num'-speaking peoples for harvesting marine mammals such as seals, porpoise, sea otters, sea lions, and whales). The most common marine mammals harvested within the Fraser River estuary included harbour seal, sea lion, and porpoise. It is understood that although there is currently no desire to harvest marine mammals; they remain culturally important to Aboriginal Groups. Details on how Project components and activities have the potential to interact with and adversely affect the availability of resources associated with the exercise of Aboriginal Interests by changing species abundance or habitat, or by causing sensory disturbance, changes in behavior, or harm (physical injury or mortality) to marine mammals is provided in Section 10 Aboriginal Consultation.

Table 4.6-1 details the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) designation for marine mammal species that may occur within the Project alignment. Other species of conservation concern, including southern resident killer whales, do not occur in the Fraser River or within the Project alignment.

Table 4.6-1 Marine Mammal Species with Potential to Occur within the Project alignment

| Common Name (COSEWIC Designation) | Scientific Name | Likelihood of Occurrence within the Project alignment |
|---|-------------------------------|---|
| Pinnipeds – Seals and Sea Lions | | |
| California sea lion (not at risk) | <i>Zalophus californianus</i> | Low (recorded in the Project alignment infrequently) |
| (Northern) Steller sea lion (Special Concern) | <i>Eumetopias jubatus</i> | Moderate (recorded in the Project alignment somewhat regularly) |
| Harbour seal (not at risk) | <i>Phoca vitulina</i> | High (recorded in the Project alignment in relatively high numbers) |

4.6.1.2 Methodology

The marine mammals assessment follows the general methodology described in **Section 3.0 Assessment Methodology**.

In early 2014, the Ministry initiated desktop studies and underwater noise modelling to support Project planning and the assessment of potential Project-related effects. The studies were designed to build on existing information and address known data gaps.

Table 4.6-2 provides a summary of the studies conducted to support the marine mammals assessment. Further detail relating to the underwater noise modelling methodology and results can be found in **Section 4.3 Underwater Noise**.

Table 4.6-2 Marine Mammal Studies to Support the Assessment

| Study Name | Purpose of Study |
|-------------------------------------|---|
| Literature review/ Desktop study | <ul style="list-style-type: none"> • Determine which marine mammals may be present in the local assessment area (LAA). • Identify key data gaps and areas of uncertainty within the LAA. • Sources of data included the <i>Species at Risk</i> Public Registry, COSEWIC Wildlife Species Database, and the BC Cetacean Sighting Network database, DFO Recovery Strategies and academic literature. |
| Modelling Study | <ul style="list-style-type: none"> • Acoustic models were used to predict the underwater noise footprint of proposed Tunnel decommissioning and bridge construction activities. These models were used to inform the marine mammals assessment. |

Selection of Representative Species

Seals and sea lions occur in or near the Project alignment seasonally, with peak abundance in the lower Fraser River and estuary typically coinciding with seasonal physical and biological factors such as availability of prey. Due to similar life histories, habitat requirements, prey preferences, hearing sensitivities, and ecological roles between seals and sea lions, harbour seal was selected as the representative species for the marine mammals VC for the purposes of this assessment. Harbour seals are also common, conspicuous, and well-studied with an established baseline of population information. They are culturally important to Aboriginal Groups and the public. They have the potential to experience similar Project-related effects as sea lions. During consultations, the importance of southern resident killer whale (SRKW) to Aboriginal Groups was acknowledged; however, SRKW have been excluded from the assessment for the following reasons:

- SRKW are not present in the Fraser River; therefore, there is limited potential for direct interaction with Project activities.
- Preliminary results of conservative underwater noise modelling indicate underwater noise generated during construction will not travel beyond the Fraser River.
- Preliminary results of fish and fish habitat studies suggested potential effects of the Project on availability of Chinook salmon are negligible.

Indicator

Change in the acoustic environment from underwater noise was used as an indicator to evaluate potential Project-related effects on marine mammals. Sound pressure level and sound exposure level are two metrics that are commonly used to assess the potential for injury or behavioural disturbance to marine mammals due to Project-related underwater noise. This assessment evaluates the effects of Project-related underwater and in-air noise on harbour seals.

4.6.1.3 Assessment Boundaries

This section describes the spatial and temporal boundaries for the assessment of marine mammals. No administrative or technical boundaries apply to this assessment.

Spatial Boundaries

The LAA and regional assessment area (RAA) for marine mammals are defined in **Table 4.6-3** and shown in **Figure 4.6-1**.

Table 4.6-3 Spatial Boundary Definitions for Marine Mammals

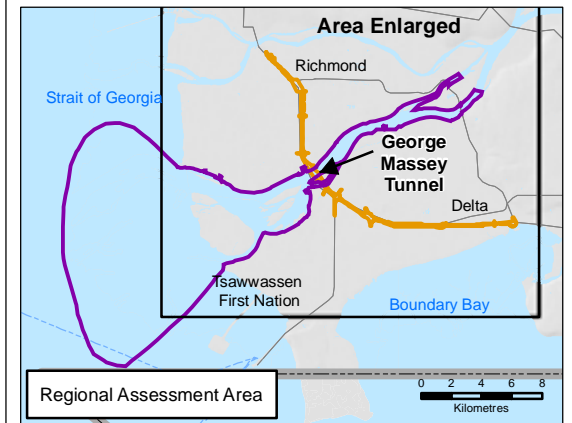

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|---|
| Local Assessment Area (LAA) | All areas where Project-related effects to marine mammals could potentially occur, including the zone of audibility for harbour seals from modelled underwater noise from construction activities. |
| Regional Assessment Area (RAA) | Encompasses a portion of the Fraser River from the river mouth upstream to Annacis Island and a portion of Roberts Bank, and provides a regional context for the ecological effects of the Project. |

The LAA boundaries were determined by considering the nature and characteristics of harbour seals as the representative VC species, as well as their potential for exposure to Project-related underwater noise, and the maximum extent of potential adverse effects. The RAA was established to provide a regional context for the assessment of Project-related effects.

Project activities during the construction phase are expected to temporarily increase underwater sound levels in the lower Fraser River above existing ambient sound levels within a certain zone upstream and downstream of the Project alignment. Within this zone, noise from Project-related activities may be audible to seals, and has the potential to cause hearing damage, or disturbance resulting in behavioural changes.

Due to the acoustic environment (e.g., riverbed sediment type, channel morphology) within the LAA, the underwater distance from the Project from which seals might hear underwater noise generated by construction activities is estimated at no more than 7.5 km. Beyond that distance, seals will not be able to differentiate Project-related underwater noise from existing ambient sound.

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on marine mammals were established based on the potential for each phase of the Project to interact with, and have an effect on, marine mammals. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, both the construction and operational phases of the Project include components and activities that could interact with, and affect, marine mammals; therefore, the following temporal boundaries will be assessed:

- Existing conditions.
- Project construction (including Tunnel decommissioning).
- Project operation (including maintenance).

Temporal characteristics of the Project phases are discussed in **Section 1.1 Description of Proposed Project**. Specific temporal considerations for the assessment of marine mammals are discussed in the context of Project interactions and potential effects in **Section 4.6.3**.

4.6.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data and describes the existing conditions of the representative species, harbour seal, in the LAA and RAA, and the factors influencing those conditions. A summary of Steller and California sea lion abundance and habitat requirements in and near the Project alignment is also provided to strengthen rationale for selection of harbour seal as a representative species for the marine mammal VC.

4.6.2.1 Regulatory Context

Regulation and management of marine mammals occurs primarily through the Marine Mammal Regulations SOR/93-56 of the *Fisheries Act*, R.S.C. 1985, c. F-14, and the *Species at Risk Act (SARA)*, S.C. 2002, c. 29.

Fisheries Act

Section 7 of the Marine Mammal Regulations prohibits the disturbance of marine mammals, unless fishing for marine mammals under the authority of the regulations. Marine animals, including marine mammals, are defined as fish under the *Fisheries Act*. The *Fisheries Act* provides for the protection of marine mammal habitat from physical alteration and introduction of deleterious substances.

Species at Risk Act

The purpose of SARA is “to prevent wildlife species from being extirpated or becoming extinct, to provide for the recovery of wildlife species that are extirpated, endangered or threatened as a result of human activity and to manage species of special concern to prevent them from becoming endangered or threatened.” Section 32 of SARA further states that “no person shall kill, harm, harass, capture or take an individual of a wildlife species that is listed as an extirpated species, an endangered species or a threatened species.”

Steller sea lion (*Eumetopias jubatus*) is the only marine mammal species listed under SARA Schedule 1 (Special Concern) that may occur in the Project alignment. The term “Special Concern” refers to species that could become threatened or endangered because of a combination of biological characteristics and identified threats (DFO 2010*b*).

Historically, Steller sea lions were the target of subsistence and commercial hunts, and were subject to predator control programs and commercial harvests. As a result, the population decreased substantially by the 1970s to approximately 25 to 33 per cent of early 1900s levels (DFO 2008). In 1971, protection for this species was provided under the *Fisheries Act*. Despite an average increase of 3.2% per year since 1971 in the B.C. population (Pitcher et al. 2007), COSEWIC upgraded the listing for this species from Not at Risk to Special Concern in 2003 for the following reasons:

- There are only three major breeding locations in B.C.
- The species is sensitive to human disturbance while on land.
- There is a threat of acute oil spills, which could hinder recovery of at-risk populations.
- There have been unexplained declines in other populations to the north and west of B.C. (COSEWIC 2003, DFO 2003, 2008).

Other potential threats to Steller sea lions include human disturbance, entanglement in fishing gear, and persecution by humans (SCBC 2009).

Provincial and Other Regulatory Designations

Steller sea lion is provincially Blue-listed (i.e., of Special Concern in B.C.; B.C. CDC 2014). Under the International Union for Conservation of Nature, the eastern Steller sea lion population (which includes the B.C. population) is listed as of Least Concern, and the western population as Near Threatened (Gelatt and Lowry 2012).

4.6.2.2 Existing Conditions

Steller Sea Lion

Steller sea lions use marine habitats to forage and terrestrial locations as haul-out sites (Jeffries et al. 2000, DFO 2010a). Steller sea lions haul out on rocky outcrops, logbooms, floats, and docks when not foraging, to avoid predators, thermoregulate, engage in social activity, rest, and reproduce. Breeding of Steller sea lions occurs from May to August (LGL Limited et al. 2009), in four rookeries: northern tip of Vancouver Island, southern tip of Haida Gwaii, as well as central and northern mainland coasts (DFO 2008, BCMCA Project Team 2011). In late summer and autumn, sea lions disperse to wintering haul-out sites. Winter haul-out sites have been identified on the southern B.C. coast, including the Strait of Georgia (Jeffries et al. 2000, DFO 2003, Olesiuk 2009). The documented haul-out site closest to the Project alignment is near Sand Heads (along the Steveston jetty) at the mouth of the Fraser River, approximately 18 km downstream of the Project (Jeffries et al. 2000, DFO 2010b). While Steller sea lions can be found year-round in marine waters (COSEWIC 2003, DFO 2010b), they occasionally venture into freshwater, as far as 35 km upriver (Olesiuk, unpublished data as cited in DFO 2010b). They also congregate in estuaries during autumn to feed on pre-spawning salmon and at the mouth of the Fraser River in spring when eulachon are running (Bigg 1985, Bigg et al. 1990, Olesiuk, unpublished data as cited in DFO 2010b). While eastern Steller sea lion may occur near the Project alignment, they are not likely to be present in large numbers. During consultation on the Project, Aboriginal Groups noted that Stellar sea lions were historically hunted in the Project area.

California Sea Lion

California sea lions congregate on rookeries off the coast of California and Mexico to mate and pup between May and August. At the end of the breeding season, they leave the rookeries and disperse. Females and juveniles remain in California and Mexico, while adult and sub-adult males travel north as far as central Vancouver Island, arriving in B.C. in September to October and departing from April to May. Approximately 3,000 California sea lions winter in B.C., where individuals feed mainly on mid-water schooling fish such as herring, hake, pollock, and dogfish (Olesiuk and Bigg 1984). Numbers have increased substantially over the past 30 years, likely due to recovery of the breeding population in California and the recovery of local herring stocks (Olesiuk and Bigg 1988). California sea lions occur in waters adjacent to the Project alignment less frequently than Steller sea lions. They have been documented hauling out near Sand Heads (along the Steveston jetty) at the Fraser River mouth (Jeffries et al. 2000, DFO 2010b).

Harbour Seal

The harbour seal is the most abundant marine mammal species in B.C. With a population estimated at about 105,000 individuals in 2008, their numbers may be approaching historic highs (Olesiuk 1999, DFO 2010a). Historically, harbour seals were hunted for pelts to the point of population depletion. Since 1970, however, there have been no commercial harvests or predator control efforts (DFO 2008, 2010a). The current population size appears to be similar to pre-exploitation levels of the 1880s, and recent increases can be attributed to population recovery since cessation of over-hunting. The highest harbour seal population density occurs in the Strait of Georgia (13.1 seals per km of shoreline), representing 37% (39,000 individuals) of the provincial population (DFO 2010a).

Harbour seals inhabit estuarine and coastal waters, and haul out on rocks, reefs, and beaches. Unlike sea lions, harbour seals do not congregate on a few large rookeries, but breed in smaller groups along shorelines throughout most of their range. In southern B.C., female harbour seals give birth to a single pup each year, from early July to late August, while hauled out on shore (Olesiuk et al. 1990, Olesiuk 1999, DFO 2010a). Harbour seal pups are relatively mature and mobile at birth and are reared in the water as well as on land (Riedman 1990). The mother and pup remain together until weaning occurs at three to six weeks after birth (Bishop 1967, Bigg 1969). Moulting (shedding of hair) occurs from late June to October during which time harbour seals are typically hauled out on shore.

During late autumn and winter, harbour seals can be at sea continuously for several weeks to feed and regain weight lost during the mating and moulting seasons. They are thought to be an inshore species, occurring within 20 km of land (Spalding 1964); however, some individuals have been observed up to 100 km from shore (DFO 2010a). Juvenile harbour seals can travel up to 525 km to forage or disperse when population densities get too high. Adults usually remain closer to their haul-outs (i.e., within about 35 km) (Frost 1997). The smaller home range used by adults suggests strong site fidelity (Pitcher and Calkins 1979, Pitcher and McAllister 1981, Lowry et al. 2001).

Harbour seals are generally non-migratory, but move locally with time of day, tides, weather, season, food availability, and to find mates (Scheffer and Slipp 1944, Bigg 1969, 1981, Frost et al. 1996, 1997, Olesiuk et al. 1995, Swain et al. 1996). They are typically seen in small groups, resting on exposed reefs, boulders, and sandbars, but can also sleep for short periods underwater on the ocean floor if no suitable haul-out is available (Baird 2001).

Harbour seals (*Phoca vitulina*) are common year-round in the Strait of Georgia (Keple 2002), relatively common in the lower Fraser River, especially in channels and sloughs (Fisher 1952), and found in proximity to the Project (Tim McCormick, personal communication, 2014). They forage at the mouth of rivers and streams and enter navigable rivers and lakes in pursuit of prey such as spawning salmon (e.g., Baird 2001). The Fraser River is one of the most important rivers in terms of seal abundance (Fisher 1952) and harbour seals have been known to travel 50 km up the Fraser River (DFO 2010a). The nearest documented haul-out site to the Project alignment is at Garry Point, on the southeastern edge of Sturgeon Bank (EAO and VFPA 2012). Fishers on the Fraser River have stated that it used to be unusual to see harbour seals far up the Fraser River, but now they are regularly observed feeding on migrating runs of eulachon and salmon (DFO 2010a, Hume 2010). Vessel operators along the river have reported seals at the river mouth and hundreds hauled-out on log booms (Hume 2010). A DFO assessment in 2000 determined that approximately 1,600 harbour seals are present in the Fraser River (Pablo 2008, DFO 2010a).

Acoustic Environment

Marine mammals use sound as a primary means of underwater communication and sensing. A considerable number of studies have been undertaken in the last decade to describe the effects of anthropogenic noise on marine organisms (Richardson et al. 1995, U.S. NRC 2003, 2005, Wright 2008).

Underwater noise due to the Project could affect marine mammal hearing, communication, or behaviour. Effects to hearing can include temporary or permanent hearing loss, or auditory masking. Behavioural effects can include increased breathing rates, more time spent under or at the water surface, changes in swimming direction or speed, or displacement or avoidance of habitat. Underwater noise could potentially result in behavioural effects, displacement, or habitat avoidance. The types and ranges of effects are highly dependent on the characteristics of the sound source, the environment in which the sound occurs, and the animal(s) receiving the sounds (Richardson et al. 1995, Southall et al. 2007).

The LAA is currently subject to underwater and in-air noise from a variety of anthropogenic sources — mainly commercial and recreational vessel traffic and industrial activity — that contribute to the ambient noise levels. Existing conditions of underwater noise currently exceed thresholds for behavioural disturbance to marine mammals approximately 20 percent of the time. Details on the existing conditions of ambient underwater sound and underwater noise levels associated with the Project are provided in **Section 4.3 Underwater Noise**.

4.6.3 Potential Effects

This section discusses anticipated interactions of Project components and activities with marine mammals, and the potential effects of such interactions. Information on the mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 4.6.4**.

4.6.3.1 Project Interactions

This section presents a preliminary evaluation of the potential effects of Project interactions on marine mammals for the purpose of focusing the assessment on those interactions of greatest importance. An overview of potential interactions between Project activities and marine mammals during Project construction is provided in **Appendix A**.

Construction: Potential interaction with, and effects on, marine mammals during Project construction may include the following:

- Physical injury during Project construction activities along the edge of Deas Slough, including pile driving, that can generate underwater noise at levels sufficient to injure the hearing of marine mammals, and injury or mortality due to collisions with construction-related vessels or equipment on land or in water.
- Behavioural changes resulting from construction activities along the edge of Deas Slough and Tunnel removal, including vibrodensification, vibratory pile driving, and operation of support vessels, that can generate underwater and in-air noise at levels sufficient to disturb, but not injure, marine mammals.
- Behavioural changes resulting from construction and operation activities that could generate atmospheric (in-air) noise at levels sufficient to disturb marine mammals hauled out on land.
- Potential effects from changes to sediment and water quality.

Operation: Project operation activities are not anticipated to generate underwater or in-air noise that can physically injure or disturb marine mammal behaviour, resulting in no adverse effects on marine mammals.

4.6.3.2 Potential Effects

Potential effects associated with the identified Project-marine mammal interactions were identified through discussions with regulators, Aboriginal Groups, stakeholders, review of the Project's Application Information Requirements, experience from past projects and activities, and professional judgement of the Project team. Potential effects from construction activities are anticipated to be similar for all marine mammals occurring in the Fraser River in the LAA.

Underwater and in-air noise generated during construction was carried forward into the assessment. Potential changes associated with other Project interactions, including potential changes to sediment and water quality and potential collisions with vessels and other construction equipment either on land or in water, were determined to have a negligible effect on marine mammals and were not considered further.

As harbour seals are not common in the Fraser River and it is not their prime habitat (marine), any short-term effects to their habitat or prey from changes in sediment and water quality will not affect their ability to feed and successfully reproduce. The change in harbour seal habitat quality between existing conditions and the Project was considered negligible.

Collisions between construction-related vessels and construction equipment and harbour seals may be fatal to a harbour seal, or an individual may recover. However, only one record of a pinniped (sea lion) strike has been reported in B.C. (2009), involving a whale watching vessel at Race Rocks Marine Reserve (DFO Marine Mammal Incident Database 1973 to October 2012). Vessel strikes were not identified as a potential threat in the DFO Management Plan for harbour seals and will not be assessed further. Due to their small size and agility, and propensity to flee terrestrial disturbance while on haulouts, the chance of a Project-related vessel or construction equipment striking a seal and resulting in injury or mortality during construction is very low and determined to be negligible and no adverse effects to marine mammals are anticipated.

Mitigation measures, including Project design measures to avoid or reduce adverse effects, are described in **Section 4.6.4**. Potential residual effects of the Project on marine mammals in terms of established criteria are discussed in **Section 4.6.5**. A determination of the significance of each residual effect, the likelihood of the residual effect, and the level of confidence in each residual effect prediction, if applicable, are also presented in **Section 4.6.5**. The potential for cumulative effects is assessed in **Section 4.6.6**.

Potential Effects of Underwater Noise

Underwater Noise Background

Sound can be classified as either pulsed or non-pulsed (i.e., continuous). Pulsed sound is brief (less than a few seconds) and intermittent, with rapid changes of sound pressure (e.g., a seismic airgun shot or an impact-hammer strike). Non-pulsed sound is characterized by gradual changes in sound pressure over time (e.g., marine vessels transiting and a vibratory pile driver in operation).

Several acoustic metrics (detailed in **Section 4.3 Underwater Noise**) are typically used to characterize pressure levels of underwater sound. Metrics used to assess potential injury and behavioural disturbance to marine mammals as a result of underwater noise generated during Project-related construction activities include:

- Root mean square (rms) sound pressure levels (SPL): the average pressure in a given time window of noise.
- Peak SPL: the maximum level attained by an acoustic pressure signal. This metric is commonly quoted for pulsed sound, and can be a criterion for assessing whether a sound could cause injury.
- Sound exposure level (SEL): the total acoustic energy received at a given location during an acoustic event, and thus the sound energy to which an organism at that location would be exposed. The SEL is also commonly used to quantify the loudness of noise.

Underwater Noise Effect Criteria

In Canada, there are currently no regulations or policies regarding underwater noise and marine mammals. Two widely acknowledged yet different sets of injury and disturbance criteria, however, are commonly used to assess sound exposure of marine mammals (see **Table 4.6-4**; refer also to **Section 4.3 Underwater Noise**):

- Regulatory criteria applied in the U.S. by the National Marine Fisheries Service (NMFS)¹ (Funk et al. 2008).
- Criteria recommended by Southall et al. (2007).

These criteria incorporate available known marine mammal reactions and various physical injury and behavioural effects due to pulsed and non-pulsed underwater noise sources.

The NMFS injury criteria are based on the rms SPL of a single pulse, averaged over the pulse duration to which a marine mammal may be safely exposed before injury occurs. The NMFS has not established injury criteria for exposure to non-pulsed sounds.

Southall et al. (2007) employ a dual criteria based on peak SPL and cumulative M-weighted SEL thresholds; the cumulative injury criteria (SEL) are specified as originating from single- or multiple-exposure events over a 24-hour period. A received sound exposure is assumed to cause injury if it exceeds either the peak SPL or the SEL criterion, or both. Southall et al. (2007) do not recommend specific SPL thresholds for marine mammal disturbance criteria.

¹ The NMFS auditory injury threshold criteria are under review but remain in use until newly proposed draft criteria are revised and formally accepted by the agency.

Table 4.6-4 National Marine Fisheries Service (NMFS) and Southall et al. (2007) Auditory Injury and Disturbance Thresholds for Seals in Water

| NMFS rms SPL Thresholds (dB re 1 µPa) | | | | Southall et al. (2007) M-weighted 24-Hour SEL Thresholds (dB re 1 µPa ² s) | Southall et al. (2007) peak SPL Thresholds (dB re 1 µPa) |
|---------------------------------------|-------------|--------------|-------------|--|--|
| Continuous Sound | | Pulsed Sound | | Pulsed Sound | |
| Injury | Disturbance | Injury | Disturbance | Injury | Injury |
| - | 120 | 190 | 160 | 186 | 218 |

Notes: SEL: sound exposure level
rms SPL: root mean square sound pressure level

Potential Effects of Underwater Noise during Construction

Proposed construction activities associated with the Project will generate underwater noise that can potentially injure or disturb marine mammals in the Fraser River. Physical injury and behavioural disturbance effects were assessed based on the distance sound propagates away from the sound source, modelled for six conservative Project construction scenarios that are likely to produce the greatest amount of underwater sound. These scenarios are as follows:

1. Localized impact pile driving along Deas Slough.
2. Localized vibratory pile driving along Deas Slough.
3. Localized vibrodensification along Deas Slough.
4. Cutter suction dredging with tug operating at the Tunnel.
5. Tugs operating at the Tunnel during Tunnel segment lifting.
6. Combined operation of tugs (Tunnel segment lifting) and sediment removal in the Fraser River.

Details on the underwater noise modelling methods, scenarios, source levels, and predicted underwater noise produced during Project construction activities are provided in **Section 4.3 Underwater Noise**. Modelling results are summarized below and in **Table 4.6-5**. It should be noted that modelled scenarios are highly conservative as they assumed construction activities in water up to 5 m in depth, and actual construction work is anticipated to occur on land or in shallow water.

Physical Injury

Project construction activities that will produce underwater noise include impact pile driving, vibratory pile driving, vibrodensification, sediment removal, lifting of the Tunnel segments, and support vessel movements. Of the six scenarios modelled (**Table 4.6-5**), in-water impact hammer pile driving in Deas Slough is the only activity that could potentially generate sound levels sufficient to physically injure the hearing of harbour seals within 53 m of the pile driving noise source. Hearing damage to harbour seals from vibratory pile driving in Deas Slough was predicted to occur within nine metres from the sound source. A worst-case scenario of 100 minutes of impact pile driving (M-weighted 24-hr SEL threshold) resulted in a zone of injury having a maximum radius of 618 m from the source (**Table 4.6-5**). Underwater noise generated during this construction scenario is not predicted to reach the mainstem of the Fraser River and will remain in Deas Slough.

These distances are conservative because they assume that 1) a seal is stationary for the duration of the sound exposure, and 2) that construction activities will occur in water. Avoidance behaviour by seals would reduce their overall sound exposure and thus the effective extent of the injury zone for impact pile driving. Furthermore, the modelled scenario considered pile driving at a depth of five metres below the water surface and localized pile installation may occur between the high and low tide water marks in dry conditions. Underwater noise is expected to be more strongly attenuated in shallow water, restricted by the surrounding slough and river banks, and absorbed by silt and clay sediments. Sediment-borne sound from impact pile driving is approximately 20 dB lower than water-borne sound (Zampolli et al. 2013). Propagation of sound through soil is expected to attenuate water-borne sound levels generated by pile driving. Thus, the six scenarios considered in this study represent the most conservative cases in terms of underwater noise emissions and potential physical injury radii.

Behavioural Disturbance

The Project-related construction activities of vibratory pile driving, vibrodensification, sediment removal, and operation of support vessels are not expected to generate sound at levels that could affect the hearing of harbour seals. However, underwater noise produced during these activities could result in behavioural disturbance.

For marine mammals, the area of potential disturbance is taken to be the zone within which sound levels exceed 120 dB rms SPL. The modelled extent of the 120 dB rms SPL zone for continuous sound sources, such as operation of tugs or vibrodensification, within which behavioural effects could occur ranges from between 441 m to 3,447 m from the source location (**Table 4.6-5**).

Although vibratory pile driving has the highest source level of all continuous sources, noise from this activity is concentrated at low frequencies (<200 Hertz), and would therefore rapidly dissipate in the shallow sediments of Deas Slough, meaning the extent of the behavioural effect zone (120 dB re 1 μ Pa SPL) would be relatively small (593 m) for this activity. The extent of the behavioural effect 120 dB re 1 μ Pa SPL zone would be smallest (441 m) for tug and barge activities during crane lifting of the Tunnel segments (scenario 5; **Table 4.6-5**).

Project-related sediment removal in preparation for Tunnel removal is assumed to occur during the prescribed least-risk timing window for the protection of juvenile salmon and eulachon (i.e., July 16 to February 28; FREMP 2006). Use of the Fraser River by seals and sea lions is known to be dependent on the seasonal migration of eulachon and salmon as a predictable and plentiful food source. This work window coincides with the time juvenile salmon and eulachon are absent from the lower Fraser River, and consequently, seals and sea lions that prey on them are also scarce or likely absent. Moreover, Project-related construction activities that have the potential to result in marine mammal behavioural disturbance will generate underwater noise that is similar to ambient acoustic levels measured in the lower Fraser River 20% of the time (see **Section 4.3 Underwater Noise**).

Seals and sea lions are known to habituate readily to human activity, including underwater noise. Previous monitoring of disturbance of seals and sea lions, at Race Rocks Ecological Reserve (Strait of Juan de Fuca, B.C.), from underwater noise generated by blasting of explosives during nearby military training indicated that behavioural changes, including displacement from a haul-out, were short term with little or no consequence on long-term use (Demarchi 2010). Shortly after each observable disturbance, animals typically returned to the haul-out, suggesting their resilience to this type of disturbance. With repeated disturbance over a period of a year, individuals continue to use Race Rocks as habitat with no measureable effect on seal or sea lion populations (Demarchi 2010).

Potential Effects of In-Air Noise during Construction

In-air noise during Project construction will not propagate into waters in the LAA at levels that could result in injury or behavioural effects to marine mammals. However, atmospheric noise could be audible to seals hauled out on land. Behavioural responses of seals to physical and acoustic disturbance range from increased alertness and sometimes threat displays to moving towards and flushing into the water. Some species have been observed to be more habituated to human disturbance (e.g., sea lions), while other species are more sensitive to disturbance (e.g., harbour seals). Studies of the distance of the disturbance source, whether land or water-based, from hauled-out harbour seals have found that the closer the disturbance,

the more likely seals are to flush into the water. The actual distance at which most flushing to the water occurs has varied from study site to study site, but has been given as approximately <100 m from disturbance, including vessels and pedestrian traffic (Allen et al. 1984, Jackson and Wilson 1990, Calambokidis et al. 1991, Brown and Prior 1998, Suryan and Harvey 1998, Jansen et al. 2010). However, the distance at which seals become alert and begin to move towards the water can be as much as 500 to 800 m at some sites (Henry & Hammill 2001, Wilson et al. 2011), and some seals begin to move into the water at 200 to 300 m for all vessels (Suryan and Harvey 1998), 300 to 500 m for cruise ships (Calambokidis et al 1991), 300 m for tour boats (Young 1998), 140 m for kayaks (Henry and Hamill 2001), and 137 m and 371 m for kayaks and stopped power boats respectively (Johnson and Acevedo-Gutiérrez 2007). Habituation to noise has also been observed in seals and sea lions hauled out on docks in direct proximity to regularly scheduled float plane operations in Victoria, B.C. (S. Meier, personal communication). In locations with regular vessel traffic, harbour seals have been observed to habituate and to allow close approach by touring boats that repeatedly visit haul-out locations (Bonner 1982, Johnson et al. 1989).

Potential behavioural effects to hauled-out harbour seals on land are not expected because of habituation. Any temporary behavioural changes will be short-term, and are not anticipated to result in population-level effects. Given this, potential changes in in-air noise levels from the Project are not anticipated to result in adverse effects to marine mammals.

Table 4.6-5 Predicted Distances within which Physical Injury and Behavioural Disturbance to Harbour Seals May Occur from Modelled Construction-related Underwater Noise Scenarios

| Construction Scenario ² | National Marine Fisheries Service Thresholds rms SPL (dB re μ Pa) | | | Southall et al. (2007) M-weighted 24- Hour SEL Threshold (186 dB re 1 μ Pa ² s) | Southall et al. (2007) peak SPL Threshold (218 dB re 1 μ Pa) |
|---|--|--|--|---|---|
| | 120 rms Behavioural Disturbance Radius Continuous Sound (m) | 160 rms Disturbance Radius Pulsed Sound (m) | 190 rms Injury Radius Pulsed Sound (m) | Injury Radius Pulsed Noise (m) | |
| 1. Impact pile driving in Deas Slough | 3,043 | 1,233 | 53 | 618 | 27 |
| 2. Vibratory pile driving in Deas Slough | 593 | 58 | 9 | n/a | n/a |
| 3. Vibrodensification in Deas Slough | 951 | <10 | n/a | n/a | n/a |
| 4. Cutter suction dredging with tug operating at Tunnel crossing | 2,726 | 11 | n/a | n/a | n/a |
| 5. Tugs operating at Tunnel crossing during Tunnel segment lifting | 441 | n/a | n/a | n/a | n/a |
| 6. Combined operation of tugs (Tunnel segment lifting) and sediment removal in the Fraser River | 3,447 | 10 | n/a | n/a | n/a |

Note: n/a = not applicable (levels were not reached).

² Construction scenarios represent the most conservative scenario in terms of potential levels of underwater noise generated

4.6.4 Mitigation Measures

As described in **Section 12.0 Management Plans**, a Construction Environmental Management Plan (CEMP) and an Operational Environmental Management Plan (OEMP) will be developed for works to be undertaken during Project construction and operation. Pertinent to marine mammals, the CEMP will include component plans, organized by environmental topic, including a Marine Mammal Management Plan. The Marine Mammal Management Plan will describe standard best practices and mitigation measures, as well as monitoring efforts, to prevent or minimize potential adverse effects to marine mammals that might otherwise result from the Project during construction. In consultation with Fisheries and Oceans Canada (DFO), mitigation measures will be developed to avoid or reduce the potential adverse effects of the Project on marine mammals (as represented by harbour seals).

4.6.4.1 Mitigation Measure #1: Marine Mammal Management

A Marine Mammal Management Plan of the CEMP will be developed in consultation with DFO to mitigate potential effects of the Project to marine mammals during Project-related underwater construction activities and will describe the measures to be followed to minimize underwater noise. Specifically, construction activities that have the potential to generate underwater sound at levels that can physically injure marine mammals, such as impact pile driving, will adhere to standard industry and best management practices such that sound thresholds for the protection of marine mammals (**Section 4.6.3.2**) are not exceeded. For example, piles could be driven through construction pads to reduce sediment-borne sound levels generated during pile driving before they reach the aquatic medium.

The Marine Mammal Management Plan will focus on best practices and mitigation measures that will be implemented to minimize underwater noise generated during marine-based construction activities, and to mitigate the potential for physical injury to marine mammals. Mitigation and monitoring measures that will be described in the plan will include, but will not be limited to:

- Limited use of engines and propellers on stationary vessels, whenever possible.
- Maintaining consistent navigation courses and speeds.
- Conducting land-based pile driving whenever possible.
- Conducting activities with the potential to generate underwater noise as efficiently as possible.
- Avoiding unnecessary idling of marine-based equipment.

- Procedures to prevent direct or indirect discharge of deleterious substances (including soil, sediment, sediment laden or turbid water, or fuel, and oils) into the marine environment.
- Implementation of marine mammal monitoring during activities anticipated to generate underwater noise, including an underwater noise monitoring program.

4.6.4.2 Mitigation Measure #2: Underwater Noise Monitoring

As part of the Marine Mammals Management Plan, underwater noise monitoring will be conducted during Project construction activities that have the potential to generate underwater sound levels that may exceed auditory thresholds that can cause physical injury to fish and marine mammals. In consultation with DFO, underwater noise monitoring is expected to be conducted during Project construction in the Fraser River South Arm and Deas and Green Sloughs to confirm underwater noise levels and ensure that injury thresholds are not exceeded, as described in **Section 4.3.4.2 Underwater Noise, Underwater Noise Monitoring**.

4.6.5 Residual Effects and their Significance

Residual effects are those that are expected to persist after implementation of mitigation measures. Implementation of mitigation measures described in **Section 4.6.4** is anticipated to prevent physical injury and minimize the potential for behavioural disturbance of marine mammals (as represented by harbour seals). Potential effects of the Project to marine mammals will be temporally limited to the construction phase and spatially limited to those activities occurring within or along the Fraser River South Arm, Deas Slough and Green Slough. Mitigation is expected to be immediately effective in protecting harbour seals from underwater noise levels that could result in injury or mortality. These mitigation measures have been used worldwide for decades to effectively mitigate potential effects of marine industrial noise on marine mammals. As a result of the implementation of mitigation measures, Project-related construction activities are not anticipated to result in population-level effects to marine mammals, including species at risk, and no residual effects on marine mammals are anticipated.

4.6.6 Cumulative Effects and their Significance

Cumulative effects result from interactions between Project-related residual effects and incremental effects of other certain and reasonably foreseeable projects and activities. The Project is not likely to result in any residual adverse effects on marine mammals. Consequently, cumulative effects are not discussed further in this assessment.

4.6.7 Follow-up Strategy

As described above, underwater noise monitoring will be conducted during Project construction in the Fraser River South Arm and Deas and Green Sloughs to confirm underwater noise levels and ensure that injury thresholds are not exceeded, as described in **Section 4.3.4.2 Underwater Noise, Underwater Noise Monitoring**.

No follow-up strategy is proposed for marine mammals.

"N/A" indicates that no Project works and/or activities are applicable to the category

4.7 Vegetation Assessment Overview

- The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development.
- Project components and activities will be primarily located within the existing Highway 99 ROW, where the vegetation consists mainly of grassy, mowed verges.
- Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary marsh, that occur in the vicinity of the Project.
- Creating comparable habitat within the Project alignment will offset unavoidable potential Project-related effect, which is limited to a small reduction in area of the cattail marsh that overlaps with Project components.
- No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.
- Applying best practices such as flagging of at-risk ecosystems to avoid encroachment during construction, removal of invasive species within areas required for the Project, and replanting of disturbed areas with native species will ensure that Project-related effects on vegetation are effectively addressed.
- No Project-related residual or cumulative effects on vegetation are expected.

4.7 Vegetation

This section presents the results of the assessment of potential effects of the Project on vegetation, and includes a description of existing conditions, potential Project-related effects and proposed mitigation measures, and an evaluation of residual Project-related and cumulative effects. The assessment of potential Project-related effects on vegetation presented in this section is confined to non-agricultural vegetated ecosystems. Potential effects of the Project on agricultural lands are described in **Section 5.4 Agricultural Use**.

In this assessment, vegetation refers to terrestrial and wetland plant species and ecosystems, particularly those considered federally or provincially to be at-risk (i.e. native species, subspecies, or ecological communities identified as being vulnerable to population declines). Potential Project interaction with aquatic vegetation species is discussed in **Section 4.4 Fish and Fish Habitat**.

4.7.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on vegetation in terms of Project setting and defines the spatial, temporal, administrative, and technical assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

No jurisdictional, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects, accessibility constraints, or gaps in data that could limit the ability to predict the effects of the Project were identified; therefore, administrative or technical boundaries are not considered relevant.

4.7.1.1 Assessment Context

The Project is located largely within the right-of-way (ROW) of an active transportation corridor and vegetation within the Project alignment is generally indicative of intense management associated with urban and agricultural development. There are, however, small portions of the Project alignment that support native vegetation, which may include species or ecosystems that are considered to be at risk by provincial or federal regulators, or are of interest to Aboriginal Groups. Additional information supporting the selection of vegetation as a VC is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**.

4.7.1.2 Methodology

The assessment of vegetation follows the general methodology described in **Section 3.0 Assessment Methodology** and applied to all VCs. Building on this approach, the assessment of vegetation was designed to focus on specific vegetation species and ecosystems considered most appropriate in the context of existing conditions in the Project area. In this context, the assessment of vegetation focuses on two sub-components as presented in **Table 4.7-1**.

Table 4.7-1 Sub-components of Vegetation

| Sub-Component | Rationale for Selection |
|-----------------------|--|
| At-risk ecosystems | Considered to be at risk (Red- or Blue-listed) by provincial regulators and potentially present within the Project alignment. |
| At-risk plant species | Considered to be at risk by provincial regulators (Red- or Blue-listed) or federal regulators (Endangered, Threatened, or Special Concern) and potentially present within the Project alignment. |

The presence and extent of at-risk ecosystems, described in terms of spatial extent and location, and species populations were used as indicators to assess trends of vegetation within the assessment area and evaluate potential Project-related effects. **Table 4.7-2** presents the indicators chosen for the assessment of Project-related effects on the two vegetation sub-components, and the rationale for their selection.

Table 4.7-2 Indicators for Assessment of Vegetation Sub-components

| Vegetation Sub-component | Indicators | Rationale for Selection |
|--------------------------|---|---|
| At-risk plant species | Presence and extent of individual species | Quantifies existing abundance and possible reduction in abundance due to Project-related clearing and habitat alteration. |
| At-risk ecosystems | Presence and extent of population(s) | Quantifies existing abundance and possible reduction in abundance due to Project-related clearing and habitat alteration. |

4.7.1.3 Assessment Boundaries

The assessment boundaries for vegetation are defined below.

Spatial Boundaries

The local assessment area (LAA) for vegetation is defined in **Table 4.7-3**, and shown in **Figure 4.7-1** and **Appendix A, Figures 1a to 1p**). The boundaries of the assessment area take into account the scale and spatial extent of potential environmental effects that are appropriate for the two sub-components.

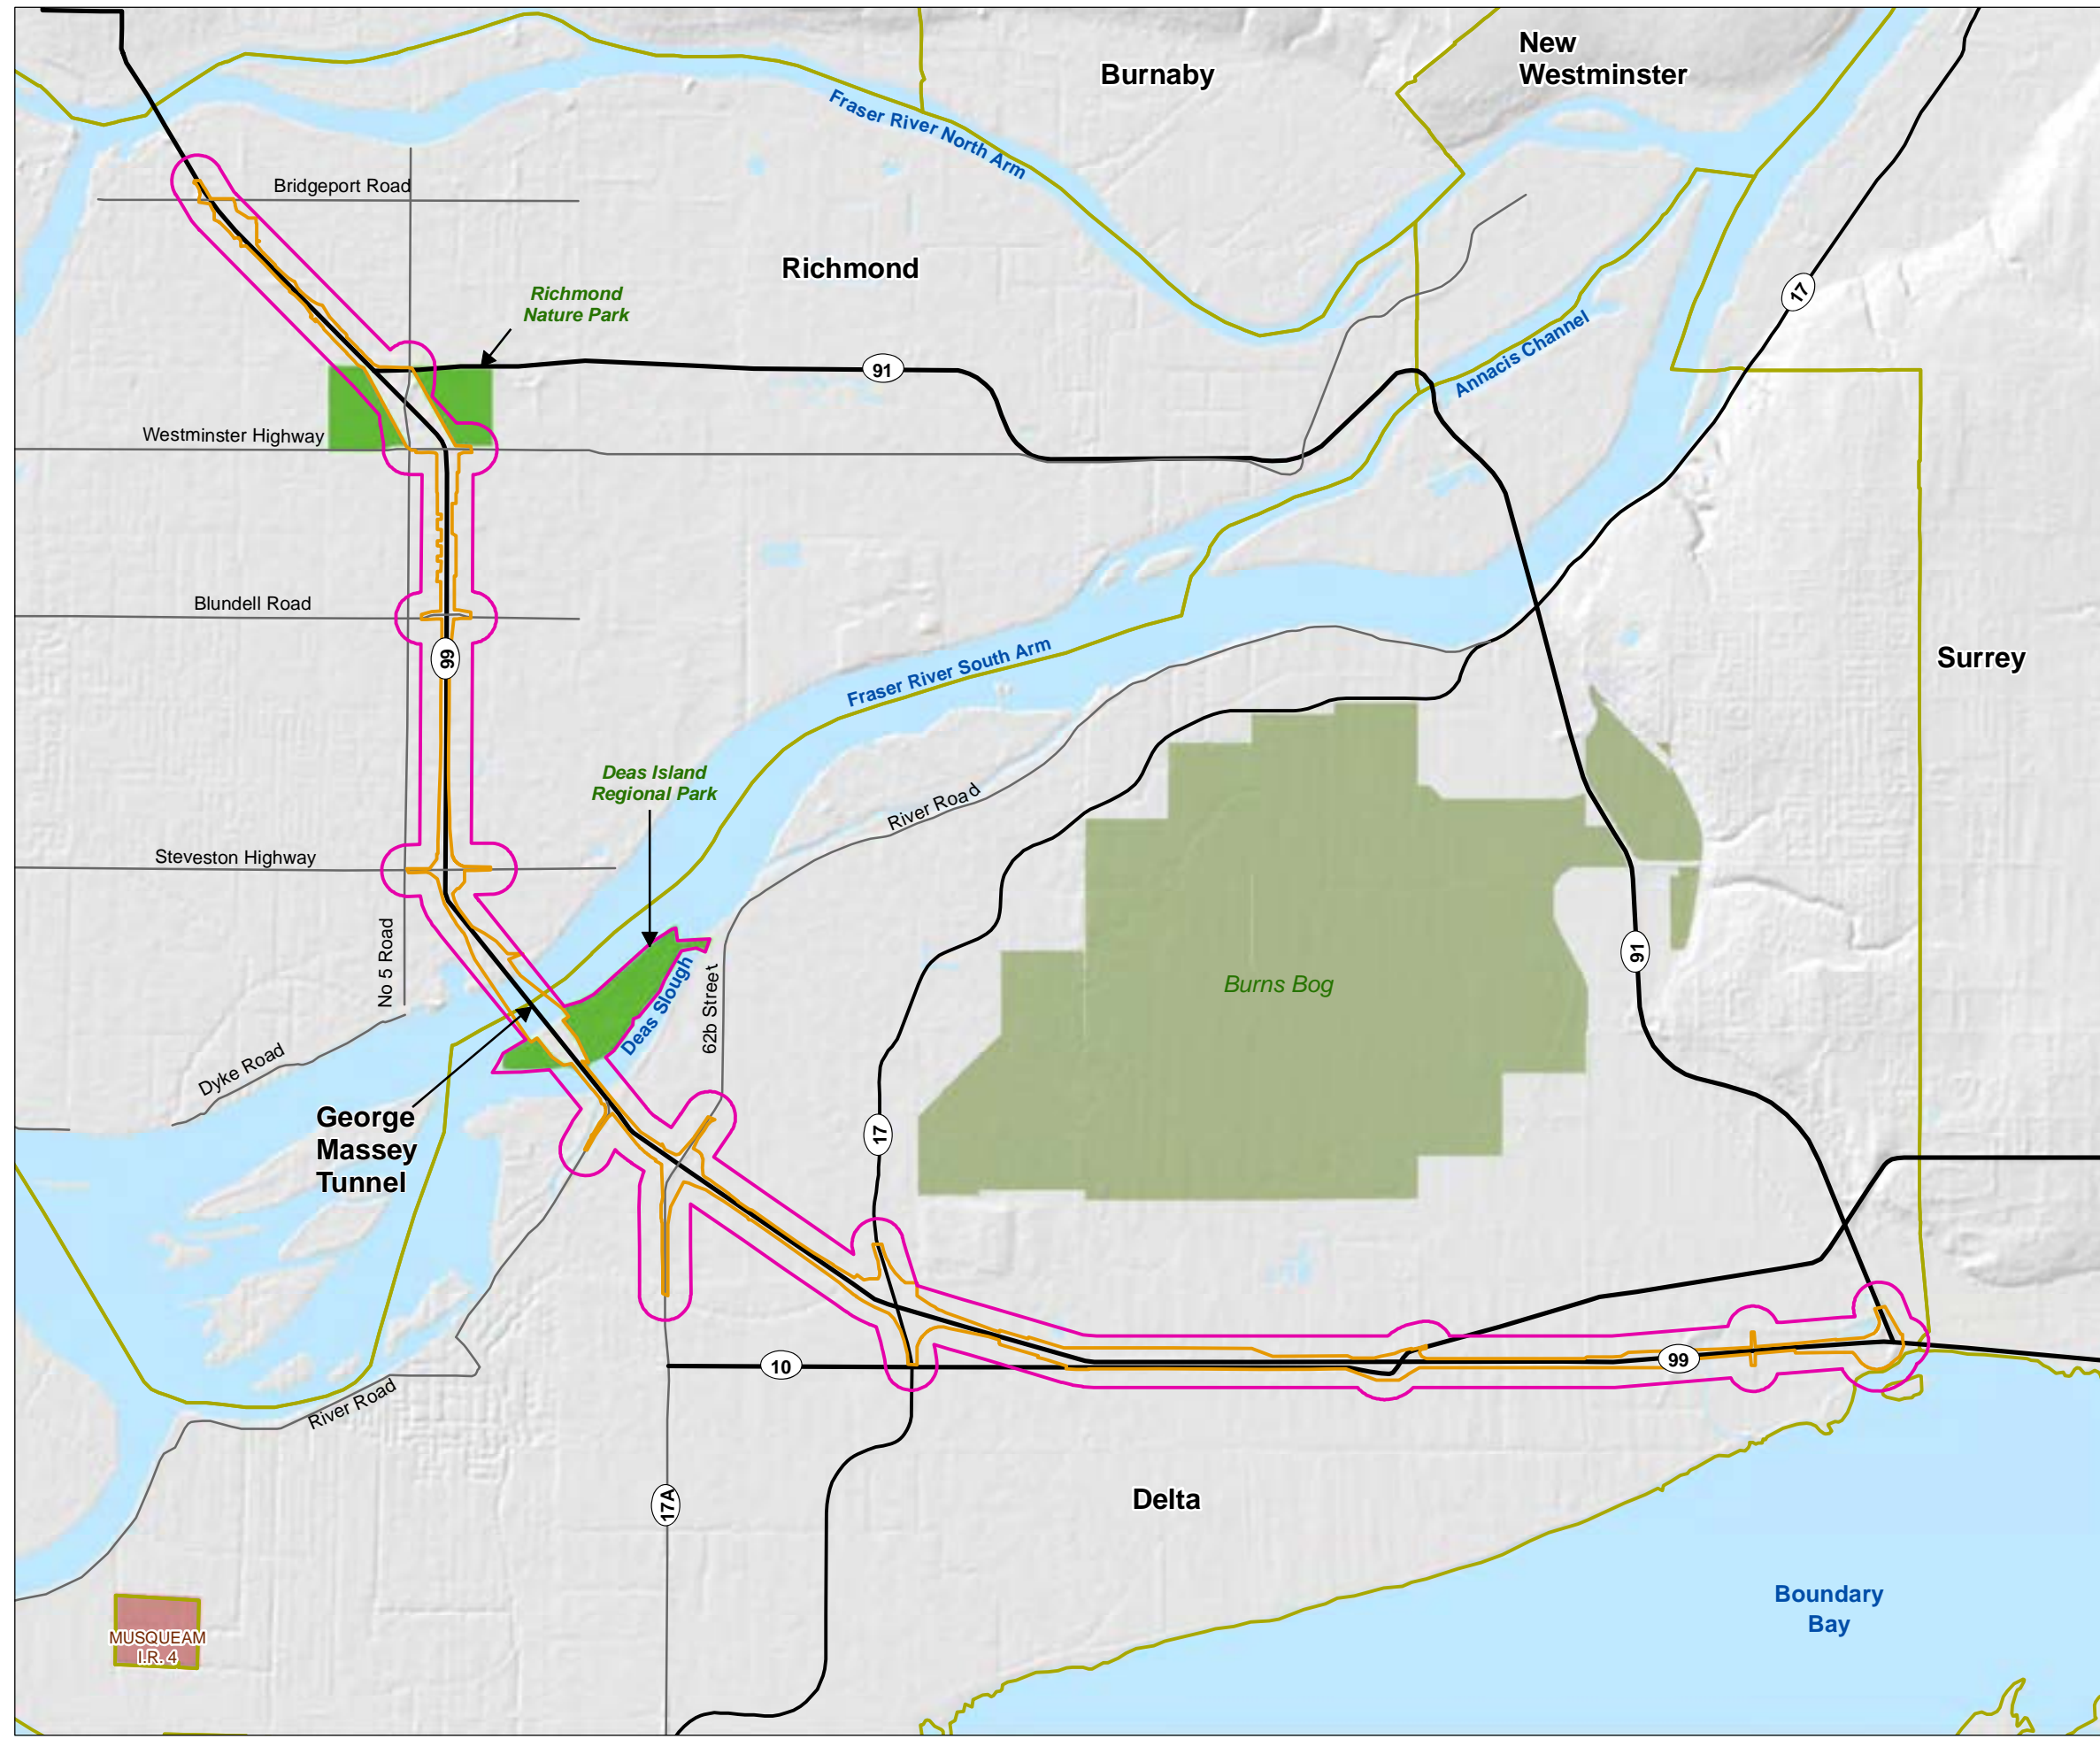

Table 4.7-3 Spatial Boundaries for Vegetation Assessment

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|---|
| Local Assessment Area (LAA) | The area within a 500-m wide corridor, extending 250 m from either side of the Highway 99 centreline, over the length of the Project alignment, including interchanges. In the area of Deas Island, the LAA is extended to include the entire island, some of which extends beyond 250 m on either side of the Highway 99 centreline. |
| Regional Assessment Area (RAA) | Project-related effects on vegetation are expected to be limited to within the LAA; therefore the RAA is defined the same as the LAA. |

The LAA for vegetation (**Table 4.7-3**) was established to encompass the area within which the Project is expected to interact with, and potentially have an effect on vegetation. In determining the LAA boundaries, consideration was given to the nature and characteristics of the vegetation sub-components, their potential exposure to habitat loss due to Project-related activities, and the maximum extent of potential effects. The Project is part of an existing transportation corridor and is located within a highly disturbed urban setting. The extent of plants and ecosystems likely to be affected by Project-related activities is constrained by the nature of adjacent land uses; therefore, a 500-m wide corridor that incorporates the Project alignment is considered sufficient to understand potential Project-related effects and to design appropriate mitigation measures where needed. Deas Island was included into the assessment in April 2016 as an extension to the vegetation study area.

Since Project-related effects on vegetation are expected to be limited to within the LAA, the RAA has been defined same as the LAA (i.e. extending over the length of the Project alignment, including interchanges).

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on vegetation were established based on the potential for each phase of the Project to interact with and have an effect on vegetation. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, both the construction and operational phases of the Project include components and activities that could interact with and affect vegetation present within the Project alignment; therefore, the following temporal boundaries were defined for vegetation assessment:

- Existing conditions
- Project construction (including Tunnel decommissioning)
- Project operation (including maintenance)

Temporal characteristics of the Project phases are discussed in **Section 1.1 Description of the Proposed Project**. Specific temporal considerations for the assessment of vegetation and its sub-components are discussed in the context of Project interactions and potential effects in **Section 4.7.3**.

Administrative Boundaries

No political, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects on vegetation have been identified; therefore, no administrative boundaries are defined.

Technical Boundaries

No technical boundaries have been identified that could impose limitations on the assessment of potential Project-related effects on vegetation.

4.7.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data, and describes the existing conditions of vegetation within the assessment areas. An overview of the regulatory context for management of vegetation as relevant to the Project is also provided.

4.7.2.1 Baseline Data Collection

In 2014, the Ministry initiated vegetation studies to support Project planning and effects assessment. Building on available information, these studies were designed to address known data gaps. Desktop and field studies conducted with respect to vegetation are summarized in **Table 4.7-4**. A comprehensive description of methods is provided in **Appendix B**, and highlights are provided below.

Table 4.7-4 Desktop and Field Studies Related to Vegetation

| Study Name | Purpose of Study |
|--|--|
| Terrestrial ecosystem mapping | To provide a baseline map of vegetation types, including agricultural lands, within the LAA and identify potential locations of at-risk plants or ecosystems for guiding rare plant surveys. |
| Assessment of at-risk plant species and ecosystems | Field surveys of selected terrestrial ecosystem mapping (TEM) polygons to verify presence of at-risk ecosystems and determine presence of at-risk plant species. |

Baseline data collected for the Project consisted of obtaining high resolution orthophotos from the Ministry and digitizing terrestrial ecosystem mapping (TEM) polygons (ecosystems) based on observable land cover. The orthophotos were of sufficient quality to accurately delineate ecosystems to a high level of confidence.

Vegetated and non-vegetated land cover types were first defined and delineated on the orthophotos using methods described in the *Standard for Mapping Terrestrial Ecosystems in British Columbia* (RIC 1998). Because much of the assessment area is disturbed, modifications to the standard approach were applied so that some cover types (e.g., roads, bare soil) could be adequately described. Factors that were considered in delineating ecosystems and other land cover types included parent material (e.g., soil), slope, aspect, and nature of vegetation cover. In addition to the desktop TEM work, a list of rare plant species that have some likelihood of occurring in the LAA was compiled based on knowledge of species habitat requirements. Further details on the TEM objectives, methods, and results are provided in **Appendix B**.

The provincial TEM standard data collection methods, as well as the provincial standard *Field Manual for Describing Ecosystems in the Field* (B.C. MOF 2010), were followed in collecting data during the field program. All ecosystems delineated as being at-risk during desktop studies were surveyed to confirm presence and habitat quality. Sampling of vegetation was conducted within 20 m-radius plots and data collected on a standard Ground Inspection Form (GIF). Within each plot, data were collected on stand structure and plant species composition. Per cent cover per species was recorded, and plant species were identified at minimum to the genus level. Total per cent cover for trees, shrubs, and herbs respectively was also recorded. TEM data for each plot were recorded on standard ground inspection forms.

In the absence of provincial standards in B.C., at-risk plant species followed methods outlined in the *Guidelines for Rare Vascular Plant Surveys* (ANPC 2012). At-risk ecosystems were mapped following the provincial *Standard for Mapping Ecosystems at Risk* (B.C. MOE 2006).

Federal, provincial, and municipal mapping and databases as well as existing reports were also consulted prior to the field surveys to understand the potential for at-risk plant species and ecosystems and included the following:

- *Species at Risk Act (SARA)* Registry
- Committee on the Status of Endangered Wildlife in Canada (COSEWIC)
- B.C. Conservation Data Centre (B.C. CDC)
- Province of B.C. online geospatial system (Hectares B.C.)
- Electronic Atlas of Flora of B.C. (e-Flora B.C.)
- Province of B.C. online mapping system (iMapBC)
- City of Surrey online mapping system (COSMOS)
- Corporation of Delta online mapping system (DeltaMap)
- City of Richmond Interactive Map (RIM)
- South Fraser Perimeter Road (SFPR) Environmental Assessment Application

The rare plant species and at-risk ecosystems surveys were focused on the Highway 99 component of the Project alignment. Roadside ditches were visually scanned as encountered. The rare plant surveys were conducted by a qualified professional using accepted protocols for field surveys

4.7.2.2 Regulatory Context

Federal

Legal protection for at-risk plant species is provided at the federal level under the *Species at Risk Act (SARA)*, S.C. 2002, c. 29, which aims to protect species at risk from becoming extinct or lost from the wild. The Act covers all Canadian wildlife species, including vascular plants, mosses and lichens, along with their critical habitats¹, that have been identified as being at risk of extinction.

The *SARA* Schedule 1 lists all plant and animal species that the Government of Canada considers to be at risk, or trending towards becoming at risk. This list is periodically updated based on recommendations provided by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC), an expert group that assesses and designates which wildlife species are in danger of disappearing from Canada (see **Table 4.7-5** for definitions of species status designations).

¹ Habitat that is necessary for the survival or recovery of a listed wildlife species and that is identified in the recovery strategy or in an action plan for the species.

Cabinet makes the final decision on whether a species will be listed under SARA Schedule 1, based on COSEWIC recommendations. Such a decision is made after the federal government has held consultations with affected stakeholders and other groups, and has considered the economic and social implications. An endangered or threatened listing under SARA mandates the formation of a species recovery team and strategy, which may in turn lead to designation of critical habitat to be protected by law.

Provincial

Although B.C. has no stand-alone endangered species legislation, the provincial *Forest and Range Practices Act (FRPA)*, SBC 2002, c. 69 enables species at risk to be designated as identified wildlife by the Deputy Minister of Environment, if the species requires special management to address the impacts of forest and range activities. Under the *FRPA*, wildlife includes endangered, threatened, or vulnerable plant species. In addition, conservation and recovery planning of at-risk species and ecosystems in B.C. are guided through the B.C. Ministry of Environment (MOE) and the B.C. Task Force on Species at Risk, and informed by the B.C. CDC.

The task of identifying at-risk species, subspecies, populations, and ecosystems (referred to collectively as elements), rests with the CDC, which is aligned with national and international organizations that cooperate to gather and exchange information on threatened elements of biodiversity. The CDC systematically collects and disseminates information on elements at risk in B.C. and assigns a provincial conservation status rank according to set criteria. Elements are placed on either a Red or Blue list for the purposes of helping to set conservation priorities and to inform more formal designations, such as by COSEWIC. The CDC designations are similar to those under SARA (**Table 4.7-5**). A Red- or Blue-list designation does not confer protection to the element or its habitat, but does highlight species and ecological communities that have particular threats, declining population trends, or restricted distributions.

Table 4.7-5 Designations for Species at Risk

| Species Status | Federal Definition ¹ | Provincial Equivalent ² |
|-----------------|--|------------------------------------|
| Extinct | No longer exist in the wild anywhere. | Red-listed |
| Extirpated | No longer exist in the wild in Canada, but occur elsewhere. | Red-listed |
| Endangered | Face imminent extirpation or extinction. | Red-listed |
| Threatened | Likely to become endangered if the factors that limit their numbers and/or range are not reversed. | Red-listed |
| Special Concern | Sensitive to or at risk from human activities or natural events but are not Extirpated, Endangered, or Threatened. | Blue-listed |
| data deficient | Insufficient information to assign a status ranking. | n/a |

Notes: ¹ COSEWIC 2014 ² B.C. CDC

4.7.2.3 Existing Conditions

General Vegetation Conditions

The LAA is within the Coastal Douglas-fir Moist Maritime (CDFmm) and Coastal Western Hemlock Eastern Very Dry Maritime (CWHxm1) biogeoclimatic subzones (BEC WEB 2014). Given the disturbance history of the area, which includes infrastructure, industrial, commercial and residential development, and agriculture, vegetated areas within the LAA typically consist of young forests or intensively managed lands. Forested areas are generally limited to the riparian areas on Deas Island. All of the ecosystems mapped in the CWHxm1 are anthropogenic.

The TEM study identified seven types of vegetated ecosystems in the LAA, comprising six wetland types, seven forested types, and one sand dune ecosystem. Four agricultural land cover types and eight non-vegetated or anthropogenic land cover types constitute the remainder of the LAA. **Appendix B** provides a summary of all mapped land cover types in the LAA.

At-risk Ecosystems

Seven at-risk ecosystems, as summarized in **Table 4.7-6** and described below, occur in the LAA (**Appendix A, Figures 1b to 1p**).

Table 4.7-6 Summary of At-risk Ecosystems within the LAA

| At-risk Ecosystem | | Description | Area within the LAA (ha) |
|--|---|---|--------------------------|
| Class Code (Polygon Number(s)) | Name (Status) | | |
| Em02 (295) | Glasswort – Sea-milkwort Herbaceous Vegetation (Red-listed) | Estuary marsh | 23.2 |
| Em05 (194 and 295) | Lyngbye’s sedge Herbaceous Vegetation (Red-listed) | Estuary marsh | 5.6 |
| Fm50 (157) | Black cottonwood – red alder/salmonberry flooded forest (Blue-listed) | Forest with long periods of seasonal flooding | 7.1 |
| Wm05 (117, 155, 367, 380, 428, 556, and 547) | Cattail marsh (Blue-listed) | Wetland dominated by emergent vegetation. Polygon 380: an artificial feature where cattails have established. | 22.6 |
| Ws51 (562) | Sitka willow – Pacific willow – Skunk cabbage (Red-listed) | Wetland ecosystem located on Deas Island, outside of Project alignment | 5.4 |
| Ws53 (564) | Western redcedar – Sword fern – Skunk cabbage (Blue-listed) | Wetland ecosystem located on Deas Island, outside of Project alignment | 6.0 |
| CDFmm/00 (427) | Large-headed sedge Herbaceous Vegetation (Red-listed) | Sandy beach dune ecosystem | 0.4 |

Notes: Class codes refer to Ecosystem class codes and are described in **Appendix B**. Numbered polygons are shown in **Appendix A, Figures 1b to 1p**.

Wetlands

Six of the seven at-risk vegetation communities identified in the LAA during the 2014 and 2016 field surveys are classified as wetlands (**Appendix A**), comprising Blue-listed cattail marsh (polygons 117, 155, 367, 380, 428, 556, and 547), Red-listed Lyngbye’s sedge salt marsh (polygon 194) and glasswort – sea-milkwort salt marsh (polygon 295), and Blue-listed black cottonwood – red alder/salmonberry flooded forest (polygon 157). Two additional wetland ecosystems, Red-listed Sitka willow – Pacific willow – skunk cabbage (polygon 562) and Blue-listed western redcedar – sword fern – skunk cabbage (polygon 564), are located on Deas Island and outside of the Project footprint.

Cattail communities are very common in the CDFmm and surrounding area, often occurring in association with shallow, open water, and roadside ditches. Such communities tend to consist of almost pure stands of common cattail (*Typha latifolia*) and often develop when cattail seeds, which germinate readily in open standing water, establish in a site. In general, such marshes can be readily created in artificial features such as roadside ditches and retention ponds. During consultation, Aboriginal Groups noted that cattails and bulrushes (tule, or 'wool' in Hul'qumi'numm) were common in the area and are important for cultural purposes (see **Section 10.1.3 Aboriginal Interests Assessment**). Aboriginal Groups have also noted that wapato, a wetland-dependent species, also occurs in the area and roots were harvested for food.

Optimal conditions for wetlands in the Lower Mainland are small (<0.5 ha) marshes within 200 m of each other, close to agricultural fields or forests with a 50:50 open water to dense vegetation cover ratio (SCCP 2015). Based on TEM and field observations completed as part of Project-related studies within the RAA, approximately 22.6 ha of cattail marsh are present along the Highway 99 corridor between Bridgeport Road in Richmond and the Highway 91 Interchange in Delta. Cattail marshes in the vicinity of the Project are isolated, characterized by dense vegetation cover with little to no open water, and thus do not provide optimal wetland conditions.

Conditions of the cattail marshes in the LAA are as follows:

- Polygon 380 (**Appendix A, Figure 1k**), situated at the Highway 99/Highway 17 interchange, is an example of a cattail marsh that has established in an artificial feature. Originally a depression created by construction of the SFPR project, this polygon now has an established cattail population that has expanded due to soil compaction and water accumulation. This marsh lacks the diversity of a natural marsh due to its young age.
- Polygon 428 (**Appendix A, Figure 1i**), situated between Green Slough and River Road, is a more natural cattail marsh than polygon 380, having been formed as part of a larger wetland complex. It supports common cattail, skunk cabbage (*Lysichiton americanum*), rein orchids (*Piper* sp.), sedges (*Carex* sp.), and rushes (*Juncus* sp.). Historical aerial photographs show this wetland was originally connected to Deas Slough but was isolated from the slough when Highway 99 was built. It is likely that this wetland is connected to Green Slough and influenced by groundwater and runoff from the surrounding area. Some standing water is also present, but pools are small and disconnected. The overall condition of this wetland is moderate to poor. There are pockets of standing water where cattails are dominant, but grasses and invasive species such as purple loosestrife (*Lythrum salicaria*) are present. The wetland margins are characterized by grassy verges dominated by sedges, agronomic grasses, and weedy herbaceous vegetation species (see **Figure 4.7-2**). The wetland is likely affected by contaminants from surface runoff associated with Highway 99 and River Road.

- Polygon 155 (**Appendix A, Figure 1l**), located on the south side of Highway 99, to the east of a series of greenhouses along Highway 10, and south of polygon 157. The wetland was likely developed as a detention pond or habitat compensation for the adjacent greenhouses, or may have been part of a historically larger wetland complex connected to Burns Bog to the north. This wetland is located just outside of the Project alignment.
- Polygons 117 and 367 (**Appendix A, Figure 1p**) on the east side of the Highway 99 and Highway 91 interchange. The wetlands appear to be constructed, either as part of the Delta Golf Course development, or during development of the highways, and are located within the highway rights-of-way. The wetlands are vegetated, with open water ditches flowing through the middle of each polygon. The ditches are likely connected by a culvert running underneath the rail tracks located parallel to Highway 99, and flow into Boundary Bay. The wetlands are dominated by reed canarygrass and the highway side is also regularly mowed. The current scope of the Project will not impact these polygons.
- Polygons 556, 547, and 562 (**Appendix A, Figures 1h and 1g**) are located on Deas Island outside of Project footprint and will not be impacted by the Project.

Note: Non-native grasses as well as cattails are visible in the foreground; willows and cottonwood are visible in the mid-ground and background.

Figure 4.7-2 Blue-listed Cattail Wetland at Highway 99 and River Road, near Green Slough (Polygon 428)

The Red-listed Lyngbye’s sedge estuary marsh in the LAA (polygon 194) is a 2.4-ha wetland located in Deas Island Regional Park (**Appendix A, Figure 1h and 1g**). This ecosystem has very limited distribution along B.C.’s coast, and requires very specific site conditions associated with estuarine systems (B.C. CDC 2013). This wetland is in good condition and is sheltered from disturbance by the park, given its location away from trails. Additional Lyngbye’s sedge estuary marsh is located at the eastern end of the LAA (polygon 295) at Boundary Bay. However, since the marsh is located on the water side of the dyke (i.e. outside of the proposed Project footprint), Project-related affects are not anticipated.

The Red-listed glasswort – sea-milkwort estuary marsh (polygon 295) is also located on the water side of the dyke at Boundary Bay and is not expected to be negatively affected by the Project footprint.

The black cottonwood – red alder/salmonberry association (Polygon 157) is a Blue-listed deciduous forest ecosystem that occurs on fluvial benches that are flooded frequently, perhaps annually, for moderately long periods, and have a high water table for prolonged periods. These conditions inhibit conifer establishment. In the LAA, this ecosystem comprises a 7.1-ha polygon near the north edge of Highway 99 (polygon 157; **Appendix A, Figure 1I**), south of Burns Bog. This ecosystem is dominated by balsam poplar (*Populus balsamifera*), willow (*Salix* sp.), red elderberry (*Sambucus racemosa*), and salmonberry (*Rubus spectabilis*). Several invasive species are present, including Himalayan blackberry, and reed canarygrass. Pools of standing water are present.

The two additional wetland ecosystems, Sitka willow – Pacific willow – skunk cabbage (polygon 562) and western redcedar – sword fern – skunk cabbage (polygon 564), are located on Deas Island and are not expected to be affected by Project-related activities since they are not within the Project footprint.

Other At-risk Ecosystems

One sand dune ecosystem, the Red-listed large-headed sedge Herbaceous Vegetation plant association, was identified during the 2014 field surveys in Deas Island Regional Park. This ecosystem is restricted to habitat found on sand beaches, dunes, and spits. It is characterized by sparse occurrences of large-headed sedge (*Carex macrocephala*) growing on medium to coarse, well-drained sand (B.C. CDC 2014). Occurrences are typically less than 0.5 ha but can occasionally cover larger areas in open dunes (0.5 to 2 ha). The occurrence in the LAA (polygon 427; **Appendix A, Figures 1h and 1g**) is a highly degraded area of about 0.4 ha that is bisected by several trails and invaded by several invasive species, including Scotch broom (*Cytisus scoparius*), and Himalayan blackberry.

At-risk Plant Species

No at-risk plant species were encountered in the areas observed during the 2014 rare plant surveys. Aboriginal Groups reported observations of two species of lupine: the native streambank lupine (*Lupinus rivularis*) and the introduced tree lupine (*Lupinus arboreas*). Streambank lupine is listed under Schedule 1 of SARA as endangered and is on the B.C. red list. The two are very similar in appearance, and it is unclear whether the observed species is the native or introduced species. One of these species has been seen in the Project LAA on

Deas Island. A critical habitat polygon is located on the east end of Deas Island (EC 2016) likely where the lupine was observed. There are no mapped occurrences of streambank lupine or critical habitat polygons within the Project alignment (iMapBC 2016, EC 2016) and no plants were observed during the at-risk plant surveys.. The suspected occurrence of streambank lupine in the LAA was not field-checked as it lies well outside of the Project alignment and no negative effects are anticipated.

Because of the highly disturbed condition of the habitats in the LAA, the occurrence of other at-risk plant species in the LAA is considered unlikely; therefore the at-risk plant species subcomponent of the vegetation VC is not considered further in this assessment. The remainder of the assessment focuses on at-risk ecosystems.

4.7.3 Potential Effects

This section discusses anticipated interactions of Project components and activities with vegetation, and potential effects of such interactions on at-risk ecosystems. Information on mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 4.7.4**. Potential residual effects (i.e., effects remaining following the implementation of mitigation measures) are described in **Section 4.7.5**. A discussion of potential cumulative effects on vegetation is presented in **Section 4.7.6**.

4.7.3.1 Project Interactions

An overview of potential interactions between Project activities and at-risk ecosystems during the construction and operation of Project components is provided in **Appendix C**. A preliminary evaluation of the potential effects of Project interactions on at-risk ecosystems, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Construction: Potential interactions of Project-related construction activities with at-risk ecosystems include the following:

- Potential disturbance of the cattail marshes, which are at-risk ecosystems, at polygons 367, 380, 428, and 117 during installation of temporary roads, bridges and detours, or clearing and grubbing of vegetation. There is also some potential for indirect disturbance through the introduction of invasive alien plants via construction vehicles or equipment.
- Potential overlap of Project components with at-risk ecosystems, including small portions of the cattail marsh located between Green Slough and River Road, adjacent to the support piers of the new bridge (polygon 428), the cattail marsh that has established at the Highway 17 interchange (polygon 380).

Operation: Once operational, Project activities (including routine maintenance) are not expected to affect at-risk ecosystems. The new bridge and interchanges will be designed in a manner that prevents the direct release of stormwater runoff from road surfaces into wetlands and waterbodies. Application of Ministry standard best practices for maintenance and vegetation management will ensure that maintenance of the new infrastructure does not affect at-risk ecosystems. Therefore, activities associated with Project operation are not expected to interact with vegetation and are not considered further in this assessment.

4.7.3.2 Potential Effects

To the extent possible, Project construction is proposed within the existing Highway 99 ROW. Potential effects to vegetation resulting from ground disturbance, clearing and grubbing, and other site preparation activities during Project construction will generally be minimized and restricted to within this ROW.

To identify at-risk ecosystems within the ROW that may be affected by the Project and determine the extent of potential effects, the areas of overlap between Project components and each at-risk ecosystem were calculated by overlaying the proposed alignment on the terrestrial ecosystem maps for the assessment area. As shown in **Table 4.7-7**, this exercise indicated that the Project alignment overlap with at-risk ecosystems is expected to be limited to small portions of two cattail marshes.

Table 4.7-7 Overlap between At-risk Ecosystems and Project Components

| Ecosystem Name | Location (Polygon Number) | Project Component Overlap (ha) |
|--|--|--------------------------------|
| Lyngbye's sedge Herbaceous Vegetation | Within Deas Island Regional Park (polygon 194) | 0 |
| Glasswort – sea-milkwort Herbaceous Vegetation | At Boundary Bay (polygon 295) | 0 |
| Large-headed sedge Herbaceous Vegetation | Within Deas Island Regional Park (polygon 427) | 0 |
| Cattail marsh | Adjacent to River Road and Green Slough (polygon 428) | 0.09 |
| | Along north edge of Highway 99, south of Burns Bog (polygon 157) | 0 |
| | East of Highway 99 and 91 interchange (polygons 117 and 367) | 2.0 |

A small portion of the cattail marsh adjacent to Green Slough at River Road (polygon 428) will be cleared of vegetation and grubbed during site preparation to accommodate installation of piles and piers for the new bridge (**Table 4.7-7**). This cattail marsh is already disturbed due to the presence of invasive plants, roadside runoff, and garbage (**Section 4.7.2.3**). Because this marsh is already degraded, due to previous activities and adjacent land uses, and is situated at the outer edges of the Project alignment, potential effects are considered minor.

The cattail marsh adjacent to the Highway 91 and Highway 99 interchange (polygons 117 and 367) could potentially be affected during Project construction (**Table 4.7-7**). The portion of the marsh polygons that overlap with proposed Project components are located within the existing ROW and are dominated by invasive plant species. Because the marshes are located within the existing highway ROW, regularly managed, and situated at the outer edges of the Project alignment, potential effects are considered minor.

Project components are not expected to overlap with the other at-risk ecosystems (polygons 194, 427, 157, and 295) identified within the Project alignment, and interaction with these polygons during site preparation activities can be avoided through appropriate planning and placement of temporary construction works and facilities.

The toe of the fill for the proposed Highway 17 off-ramp may encroach into the verges of the cattail marsh Highway 99/Highway 17 interchange (polygon 380). As described in **Section 4.7.2.3**, this cattail marsh, which has developed in a depression that was created during the construction of Highway 17, is surrounded by roads and a managed grassy verge and is currently subject to periodic disturbance for highway maintenance purposes.

4.7.4 Mitigation Measures

A hierarchical approach based on the four types of mitigation as outlined below was used in identifying strategies to avoid or minimize potential Project-related effects:

- **Avoidance:** Measures to avoid potential effects on the VC have been/will be incorporated into project considerations such as site and route selection, scheduling, design, and construction and operation procedures and practices.
- **Minimization:** Where potential effects on the VC cannot be avoided through project considerations, standard mitigation measures, best management practices (BMPs), and construction and operation environmental management plans (EMPs) will be implemented to minimize potential Project-related effects or reduce them to acceptable levels.

- Restoration or Habitat Enhancement: Where potential Project-related effects cannot be avoided or minimized through standard mitigation measures, best practices, or implementation of EMPs, affected components will be restored on-site to pre-Project conditions.
- Compensation/offset: Where on-site restoration is not feasible, appropriate means to counteract, or make up for potential Project-related effects on the VC will be identified.

4.7.4.1 Avoidance

The Project has been designed to be located largely within the existing Highway 99 ROW, in areas that contain minimal natural vegetation, thereby avoiding potential overlap with sensitive ecosystems. Temporary facilities, such as construction laydown areas and site access roads, will be designed to avoid overlap with at-risk ecosystems present within and adjacent to the Project alignment. Perimeters of at-risk ecosystems with the potential to be affected by Project construction activities will be annotated on construction drawings and flagged in the field to minimize accidental encroachment. These measures are expected to prevent any potential adverse effects on the at-risk ecosystems within Deas Island Regional Park (polygons 194 and 427) and along the north edge of Highway 99, south of Burns Bog (polygon 157).

4.7.4.2 Minimization

Project Design

Engineering considerations indicate that a slight overlap between the proposed bridge support piers and the cattail marsh adjacent to River Road (polygon 428) cannot be avoided; however, through Project design, this unavoidable overlap will be minimized and confined to the edges of the marsh, where it will not affect the functionality of the ecosystem.

Effects of Project construction on the recently-established cattail marsh near the Highway 17 Interchange (polygon 380) will also be mitigated by applying design considerations to minimize the amount of ground disturbance within the marsh.

Best Management Practices and Environmental Management

Environmental protection measures that will be implemented during Project construction and operation to prevent or minimize potential effects on vegetation will be outlined in a Construction Environmental Management Plan (CEMP), and subsequently in an Operational Environmental Management Plan (OEMP), as described in **Section 12.0 Management Plans and Follow-up Programs**. The CEMP will include a Terrestrial Vegetation and Wildlife Management Plan that will describe standard best practices and Project-specific mitigation measures to prevent or minimize potential adverse effects on vegetation that might otherwise result from the Project during construction. Key elements of the plan are discussed below.

Terrestrial Vegetation and Wildlife Management

A Terrestrial Vegetation and Wildlife Management Plan will be developed as part of the CEMP to minimize potential construction-related effects on vegetation and wildlife. The plan will describe measures to be implemented to minimize disturbance and loss of vegetation—specifically, the cattail marshes at River Road (polygon 428) and the Highway 17 Interchange (polygon 380). Such measures include, but are not limited to the following:

- Limiting access points for heavy machinery to prevent soil compaction within and adjacent the cattail marshes.
- Placing site infrastructure as close as possible to the road verges during detailed design to minimize the area to be cleared within the cattail marshes.
- Not storing machinery and construction materials in or on the edge of the marshes.
- Incorporating a collection and distribution system to convey and discharge stormwater runoff to appropriate upland infrastructure for proper treatment.
- Replanting exposed soil and reclaimed areas with native plant species, including species of importance to Aboriginal Groups, such as cattails, wapato, and berry-producing species such as *Vaccinium* sp.

Implementation of mitigation measures listed above, which reflect standard mitigation and best management practices, is expected to prevent any effects associated with encroachment on the ecosystems.

Invasive Species Management

To reduce potential invasion of at-risk ecosystems by alien vegetation species, monitoring and, if necessary, control of invasive plant species will be undertaken during construction. Species for which there is a legal requirement to control under the B.C. *Weed Control Act*, R.S.B.C. 1996, c. 487, as well as species that are listed by the Invasive Species Council of Metro Vancouver will be targeted. Invasive species management measures, including site-appropriate monitoring and control methods for different species and conditions, will be prepared and implemented as part of the Terrestrial Vegetation and Wildlife Management Plan.

Equipment hygiene is essential to managing the spread of invasive species. Contractors will comply with *Best Practices Guide for Managing Invasive Plants on Roadways* (B.C. MOTI and ISC B.C. 2013), including cleaning, inspecting, removing, and safely disposing of propagules of invasive plants (e.g., roots, stems, segments) from vehicles and equipment prior to entering the Project construction area. To reduce the spread of invasives in other areas via dumping, the Terrestrial Vegetation and Wildlife Management Plan will also include the requirement for disposal of invasive species and soils contaminated with invasive species at appropriate facilities, in accordance with the BC Organic Matter Recycling Regulation.

The above measures are expected to prevent potential effects of introduction and propagation of invasive species on the extent and functionality of at risk ecosystems.

4.7.4.3 Habitat Enhancement

As discussed in **Section 4.7.2.3**, the cattail marsh adjacent to River Road (polygon 428), which overlaps with the Project, is currently in a highly disturbed state and is influenced by stormwater runoff from the adjacent road network. The following measures are proposed to improve the functionality of this ecosystem:

- Removal of invasive species and garbage from the marsh, and revegetation using native species as appropriate to improve habitat quality in the area surrounding the new bridge support piers.
- Installation of an appropriate stormwater management system for the upgraded highway and the new bridge to avoid potential introduction of contaminants into the ecosystem through road runoff.

The above measures are expected to improve the quality and viability of the ecosystem within polygon 428, and counteract potential effects of the small overlap with the proposed bridge support piers.

The cattail marsh near the Highway 17 interchange (polygon 380), which may also overlap with the Project, developed within the past three years as a result of colonization of standing shallow water by cattails (**Section 4.7.2.3**). It is anticipated that shallow water conditions will persist in and around this area during and after Project construction. Once Project construction is complete, available areas of open water will be revegetated with native cattails. Given the history of its development, this marsh is expected to be recolonized successfully and recover from construction-related disturbance if shallow-water habitat is retained during and after construction.

Habitat enhancement features are generally anticipated to become fully productive and viable within two to four years following restoration, based on cattail recolonization of the wetted area (Sojda and Solberg 1993) The biggest risk associated with using habitat enhancement as a mitigation measure, is if the habitat never becomes fully functional and consequently does not result in the rehabilitation of the cattail habitats. To address this risk, the effectiveness of the proposed enhancement features for the Project described above will be confirmed through a follow-up monitoring program.

4.7.4.4 Habitat Offsetting

Unavoidable Project footprint effects on the cattail marsh near River Road will be offset through the creation of comparable cattail marsh habitat within the Project alignment. This habitat will be determined in consultation with Aboriginal Groups and created during Project construction and will be subject to monitoring during and after construction to ensure that it is functioning as intended. The establishment of comparable cattail marsh within the Project alignment is expected to offset the partial loss of wetland area within polygon 428.

4.7.5 Residual Effects and their Significance

All potential Project-related effects on vegetation that cannot be avoided through Project design and implementation considerations are expected to be fully addressed through minimization, enhancement, and offsetting measures discussed in **Sections 4.7.4.2 to 4.7.4.4**, and result in no residual effects.

Measures proposed to avoid or minimize Project-related effects on vegetation, including minimizing construction-related disturbance, invasive species management, and stormwater management, were identified based on standard best practices and proven methodologies. Accordingly, there is a high level of confidence in the effectiveness of these measures and their ability to prevent Project-related effects on sensitive ecosystems.

As evidenced by the recent establishment of the cattail marsh at the Highway 17 intersection (polygon 380), viable conditions for the successful establishment of native cattail marshes exist within and adjacent to the Project alignment. Therefore, the likelihood of success of revegetation as part of restoration of the cattail marsh at Highway 17 and development of a comparable ecosystem to offset the partial loss of the cattail marsh along River Road, resulting in no adverse residual effect on at-risk ecosystems, is considered high.

There is a high level of confidence in the above predictions based on good understanding of the development of the wetland (anthropogenic vs. natural), an analysis of current condition, location relative to the Project area, and consideration of potential for recovery. Uncertainty surrounding this determination is the potential for failure of the ecosystem due to hydrology changes; however, if the landscape surrounding the wetland is not altered, there should be sufficient surface runoff to support cattail regrowth. Based on these criteria, and considering that no residual effect is anticipated, no risk analysis is required.

4.7.6 Cumulative Effects and their Significance

As discussed in **Section 4.7.5**, the Project is not likely to have any residual effect on vegetation. Therefore, a cumulative effects assessment is not necessary, and was not undertaken.

4.7.7 Follow-up Strategy

The habitat cattail marsh that will be established to offset the partial loss of wetland area within polygon 428, will be subject to monitoring during and after construction to ensure that it is functioning as intended.

APPENDIX B

Terrestrial Ecosystem Mapping Methods, Objectives, and Results

Overview and Objectives

A review of the existing information and the state of knowledge pertaining to TEM was undertaken to identify key data gaps and areas of uncertainty regarding vegetation and other land cover in and around the LAA. Study components included searches of available online databases for at-risk ecosystems, as defined by B.C. MOE, and wetlands, as defined by regulations under the *FRPA*, and the *Federal Policy on Wetland Conservation* (CWS 1991).

The results of the TEM study provided information necessary to understanding not only the existing conditions of the vegetation VC and its sub-components, but also the value of habitat in the study area for terrestrial wildlife.

The TEM study area included a broader spatial scope than the Project alignment. The study area selected was of sufficient size to adequately represent existing vegetation conditions in and around the Project alignment and to capture local variability and area uniqueness. The study area comprised a 500-m wide corridor along the existing Highway 99 corridor and the interchanges associated with the Project (i.e., 250 m on either side of the highway and interchange centrelines), extending from Bridgeport Road to Highway 91 Interchange in Delta.

The study objectives were to develop a quantitative inventory of vegetated, non-agricultural land cover types, with emphasis on at-risk ecosystems and locations having potential for at-risk species. Several at-risk ecosystems, generally wetlands, occur within the Coastal Douglas-fir Moist Maritime (CDFmm) biogeoclimatic subzone variant that comprises the study area. Wetlands are sensitive to disturbance, are rare on the landscape, and have potential to contain habitat for at-risk plant and wildlife species that occur infrequently in the Lower Mainland, and typically in small, highly fragmented locations adjacent to developed areas.

Methods

Two ecological systems of classification were used to describe the ecology in the study area: Ecoregion Classification and the Biogeoclimatic Ecosystem Classification (BEC). Ecosystems were defined and delineated based on the methods outlined in the *Standard for Terrestrial Ecosystem Mapping in British Columbia* (RIC 1998). Much of the study area is disturbed, and some modifications to the standard were therefore necessary; for example, hedgerows and abandoned fields were identified because they may provide wildlife habitat. Classification of land cover was designed to support wildlife habitat suitability modelling.

TEM Pre-typing and Delineation

Preliminary typing of land cover was carried out using high-resolution ortho-imagery to delineate terrestrial ecosystems before field surveys were undertaken. Delineation was done by viewing each orthophoto and drawing polygons around homogeneous landform or vegetation elements to separate areas into similar-looking units. Factors considered in delineation included parent material, slope, aspect and vegetation cover. For the purposes of the vegetation surveys, farm fields were delineated based on crop type and level of activity (actively farmed vs. fallow or abandoned). Due to the low relief and highly disturbed nature of the landscape, stereoscopic air photo interpretation was not necessary, and polygon interpretation confidence was high.

Ecosystem Classification

Each ecosystem polygon was classified and the details entered into a Microsoft Excel TEM database. Core information entered in the ecosystem database for each polygon included:

- Polygon number.
- Biogeoclimatic zone, subzone and variant.
- Ecosystem labels (decile, site series, modifier(s) and structural stage: recorded up to two times per polygon).
- Polygon area (ha).
- Comments: additional information on the polygon, such as field check plot numbers.

Each ecosystem polygon was classified as either a single ecosystem unit (simple label) or a complex unit, with one to three (maximum) ecosystem units per polygon. Each unit included a number of site series. Each site series was further described using ecosystem site modifiers. Site modifiers are site-specific factors that can be directly related to management interpretations of different site series. These include factors such as aspect, soil texture, depth and certain specific terrain features.

Each polygon was assigned one or two site series, which were recorded as a two-digit number or letters and transcribed onto the map with their corresponding two-letter code, based on the characteristics listed above. A complete list of site series and additional non-vegetated codes for each polygon is stored in a TEM database. Vegetated ecosystems were defined as any forested, shrubby, or grassy ecosystem. Agricultural ecosystems are vegetated areas that are managed for crops or livestock. Non-vegetated and anthropogenic ecosystems include site series codes with sparse to no vegetation cover, such as exposed soil, developed areas and road surfaces. For the complex units, only those ecosystems estimated to cover approximately 10 per cent or more of the total polygon area were recorded. Anthropogenic disturbances, such as roads, buildings and rail lines, were assigned non-vegetated TEM codes.

TEM Field Sampling

In total, 490 polygons were mapped for the entire TEM study area (which is larger than the LAA). Of these, 110 polygons were excluded from field-checking because they were easily identified and classified on images as urban, rural, or road surface. The study area was further reduced to 100 polygons that are within the LAA. The entirety of Deas Island, was also included in the mapping in April 2016. Field-checking of the remaining polygons was done by a team of two, composed of a TEM mapper and an at-risk plant botanist or wildlife biologist, depending on location.

Mapping, field work, and data collection were based on provincial TEM standards and methods (RIC 1998, B.C. MOF and B.C. MOE 2010). Field-checking was conducted using level-five intensity (i.e., five to 15 per cent of polygons were field-checked), a level considered appropriate for the large size and disturbance history of the study area. A total of 11 ground inspection forms (Form No. FS882) cards were completed and 41 visual assessments were conducted equalling 55% of the Project footprint being field-checked.

Sampling was conducted within 20 m-radius plots. Within each plot, data were collected on stand structure, and vascular and non-vascular plant species composition, where applicable. Plants were identified to the genus level, at minimum, and per cent cover per species. Total cover for trees, shrubs and herbs was also recorded. In agricultural areas, information on age of the field (if abandoned or fallow) and cover crop type were recorded. Other data gathered at each plot included landscape form, ecosystem, crown closure (where applicable), and structural stage (where applicable).

Photographs were taken from the centre of each plot towards each cardinal compass point, with additional photographs showing crown closure and a general overview of understory vegetation. Coordinates of the centre of the plot were collected using a GPS.

To assess wetland plant communities that had been identified within the study area, systematic surveys of vegetation cover within these areas were conducted using the procedures for site description and identification described in the *Wetlands of British Columbia: A Guide to Identification* (MacKenzie and Moran 2004).

At-risk ecosystems were identified and field-checked to confirm presence and habitat quality. Sensitive ecosystems were defined to include old-growth forests, mature forest stands, and wetlands.

Vegetation field sampling involved the collection of detailed information on forest cover, shrub, and herb layers, and general site characteristics. Vegetation survey plots were completed in pre-selected (non-random) locations where the occurrence of at-risk plants was possible. The information collected in the field was then used to update and confirm the digital TEM product. Methods and data collection followed the *Field Manual for Describing Terrestrial Ecosystems* (RIC 1998, B.C. MOF and B.C. MOE 2010), using visual assessments to ground-truth vegetated ecosystems.

Results

The study area (described above) is in the Lower Mainland (LOM) Ecoregion (Demarchi 1996). The LOM ecoregion is divided into ecosections; the study area falls within the Fraser Lowland (FRL) ecosection, which comprises the Fraser delta, estuary, lowlands, and associated uplands. The FRL has been formed primarily by sediments washed down the Fraser River (Demarchi 1996). The assessment is within the Coastal Douglas-fir Moist Maritime (CDFmm) biogeoclimatic subzone.

In general, the vegetated areas within the study area are representative of young forests and intensely managed areas. Urban and agricultural development within the study area has resulted in a landscape that is highly modified from its natural state. In the study area, most of the land cover comprises cultivated fields and built-up areas (i.e., residential, industrial and commercial). Small areas of remnant forest occur, however the forests in these areas are young, having been logged or cleared one or more times in the last century. Patches of remnant forest are also located within protected areas such as Deas Island Regional Park, Richmond Nature Park, and Burns Bog.

Table 1a provides a summary of CDFmm ecosystems and other land cover types identified in the study area. Descriptions of the non-forested ecosystem types are provided in the main body of the vegetation VC assessment. Forested ecosystem types identified in the study area follow **Table 1a**.

Table 1a Summary of Ecosystems and Other Land Cover Types in the Study Area

| Coastal Douglas-fir Moist Maritime (CDFmm) | | | |
|---|--|---|------------------------------|
| Code | Name | Description | Area (ha)¹ |
| DS | Douglas-fir – salal (CDFmm/01) | Zonal | 14.1 |
| RK | Western redcedar / Douglas-fir – Kindbergia (CDFmm/05) | Very poor to medium, somewhat dry to fresh | 3.5 |
| RF | Western red cedar/grand fir – foamflower (CDFmm/06) | Rich to very rich, somewhat dry to fresh | 170.3 |
| RS | Western redcedar – Snowberry (CDFmm/07) | High bench floodplain | 7.4 |
| CD | Black cottonwood – Red-osier dogwood (CDFmm/08) | Medium bench floodplain | 7.4 |

The Coastal Douglas-fir Moist Maritime Douglas-fir-Salal (**CDFmm/01**) sites are zonal (neutral slope) forested sites characterized by slightly dry to fresh soil moisture regime, with very poor to medium nutrient levels within the soil. These sites occur around mid-slope on gently sloping landforms (Meidinger and Pojar 1991). Soils on these sites vary depending on parent material ranging from Regosols on lava flows and recent burns to Podzols in forested ecosystems.

Western redcedar/Douglas-fir – *Kindbergia* (**CDFmm/05**) are considered medium sites. These have very poor to medium soil nutrients, and somewhat dry to fresh moisture.

Richer site series are represented by the Western redcedar/Grand fir–Foamflower (**CDFmm/06**). These contain rich to very rich soil nutrients and moderately dry to very moist soil moisture. Vigorous vegetation growth and species diversity, including a greater number of herbaceous species in the understory, are characteristic of these ecosystems.

Poor, wet bog sites (Lodgepole pine – sphagnum (**CDFmm/10**) occur mainly in Richmond Nature Park. These sites have poor soil nutrients and saturated soils. Vegetation diversity tends to be low, restricted to only a few species that are tolerant of fluctuating water levels. Soils are generally organic peat mosses.

Floodplain sites are represented by western redcedar – Snowberry (**CDFmm/07**) (high bench floodplain) and black cottonwood – Red-osier dogwood (**CDFmm/08**) (medium bench floodplain). High bench sites are most infrequently flooded (>5 years), while medium bench floodplains are flooded at least every five years and often annually.

Sites with strongly fluctuating water tables, western redcedar – Indian-plum (**CDFmm/13**), have a soil moisture regime that fluctuates over the growing season. These sites are usually saturated during wet winter months and dry during the summer.

4.8 Terrestrial Wildlife Assessment Highlights:

- Terrestrial wildlife along Highway 99 consists primarily of common species of raptors, riverine birds, and small mammals.
- Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge.
- No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.
- The application of best practices during future stages of design and construction will largely avoid or mitigate Project-related effects on wildlife and wildlife habitat.
- Installation of flight deflectors such as hedgerows at appropriate locations along the highway will mitigate potential Project-related increase in traffic collision risk for barn owls.
- Nesting opportunity provided by the new bridge will offset the loss of barn swallow nesting habitat due to removal of the Deas Slough Bridge.
- Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed.
- No significant Project-related residual or cumulative effects on terrestrial wildlife are expected.

4.8 Terrestrial Wildlife Assessment

This section presents the results of the assessment of potential effects of the Project on terrestrial wildlife, and includes a description of existing conditions, potential Project-related effects and proposed mitigation measures, and an evaluation of residual Project-related and cumulative effects.

Terrestrial wildlife includes the birds and mammals that live predominantly or entirely on land. Amphibians are addressed in **Section 4.5 At-Risk Amphibian Assessment**, and plants and ecosystems are addressed in **Section 4.7 Vegetation Assessment**.

4.8.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on terrestrial wildlife in terms of the Project, and defines and rationalizes the spatial, temporal, administrative and technical assessment boundaries.

4.8.1.1 Assessment Context

Terrestrial wildlife species and their associated habitat occur within the Project alignment, and could interact with activities associated with proposed highway widening and interchange upgrades, construction of the new bridge, and decommissioning of the Deas Slough Bridge. Terrestrial wildlife that may be affected by Project-related activities includes species that are of interest to the public, Aboriginal Groups or regulatory agencies. In addition, there are legally binding requirements that protect certain species and, in some cases, their habitat (see **Section 4.8.2.2**).

The VC selection for wildlife species is briefly described below (**Table 4.8-1**), and in greater detail in **Section 3.1 Issues Scoping and Selection of Valued Components**. The following species / species groups were excluded as VCs:

- Sandhill crane (*Grus canadensis*), short-eared owl (*Asio flammeus*), and grouse are unlikely to occur within the Project alignment because no suitable habitat has been identified.
- Ring-necked pheasant (*Phasianus colchicus*) have been identified as important to Aboriginal Groups but is not a native species.
- Red fox (*Vulpes vulpes*), American black bear (*Ursus americanus*), elk (*Cervus elaphus*), North American porcupine (*Erethizon dorsatum*), snowshoe hare (*Lepus americanus*), and grey wolf (*Canis lupus*) were traditionally harvested by Aboriginal Groups but are believed to be extirpated from the Project alignment.
- American beaver (*Castor canadensis*), common muskrat (*Ondatra zibethicus*), American mink (*Neovison vison*), American marten (*Martes americana*), striped skunk (*Mephitis mephitis*), Douglas's squirrel (*Tamiasciurus douglasii*), and raccoon (*Procyon lotor*) have been identified as important to Aboriginal Groups and likely occur within the Project alignment; however, Project-related Highway 99 improvements are not anticipated to impact their habitat requirements.
- Deer are found in nearby habitats (e.g., Burns Bog) and are important to Aboriginal Groups; however, Project-related Highway 99 improvements are not anticipated to result in an increase of current collision risk, based on the review of existing Ministry collision data.

Project-related effects anticipated to have a direct influence on terrestrial wildlife include habitat loss, habitat alteration, and mortality. Changes to habitat availability and function may occur during Project construction as a result of habitat loss or alteration. Indirect effects to terrestrial wildlife may occur through changes to other environmental components such as sediment and water quality (**Section 4.2 Sediment and Water Quality**), atmospheric noise (**Section 4.10 Atmospheric Noise**), and vegetation (**Section 4.7 Vegetation Assessment**).

Where appropriate, information from these sections has been cross-referenced in this assessment. Information on Project design, construction, and operation as it relates to potential terrestrial wildlife effects have also been included (**Section 1.1 Description of the Proposed Project**). There is no indication that river hydraulics and morphology changes as a result of the Project will have any influence on wildlife habitat. There are no in-river piers and Tunnel decommissioning will be a temporary activity that is not anticipated to alter the riparian area (**Section 4.1 River Hydraulics and River Morphology**). For example, sedimentation as a result of Tunnel decommissioning will likely be within the range of what occurs naturally during freshet. Accordingly, river hydraulics and morphology effects on terrestrial wildlife are not considered further.

4.8.1.2 Methods

The assessment of terrestrial wildlife follows the methodology described in **Section 3.0 Assessment Methodology** and applied to all VCs. Building on this approach, the assessment of terrestrial wildlife was designed to focus on specific wildlife species considered most appropriate, given existing conditions within and adjacent to the Project alignment. In this context, the assessment of terrestrial wildlife focuses on three sub-components: upland birds, riverine birds and bats, and mammals (**Table 4.8-1**).

Table 4.8-1 Sub-components for the terrestrial wildlife VC

| Sub-component | Rationale for Selection |
|---------------|--|
| Upland birds | <p>Individual birds, eggs, and active nests are protected under the <i>Migratory Birds Convention Act</i> (MBCA), S.C. 1994, c. 22.</p> <p>Section 34 of the <i>Wildlife Act</i>, R.S.B.C. 1996, c. 488 prohibits possessing, taking, or destroying (i) a bird or its egg, (ii) the nest of an eagle, peregrine falcon, osprey, or heron, or (iii) the nest of a bird not mentioned in (ii), when the nest is occupied by a bird or its egg.</p> <p>American bittern, great blue heron (<i>fannini</i> subsp.), rough-legged hawk, peregrine falcon (<i>anatum</i> subsp.), barn owl, short-eared owl, olive-sided flycatcher, common nighthawk, and barn swallow are federally or provincially listed as at-risk and have been observed in the local assessment area (LAA) or regional assessment area (RAA). Raptors (e.g., bald eagle and osprey) and herons have been identified as culturally important to Aboriginal Groups. During consultation activities, Aboriginal Groups have noted that bald eagle have been observed within the LAA.</p> |

| Sub-component | Rationale for Selection |
|-------------------------|---|
| Riverine birds and bats | As above for the MBCA and section 34 of the <i>Wildlife Act</i> . Double-crested cormorant, cackling goose, tundra swan, Caspian tern, and western grebe are provincially listed as at-risk (Red or Blue), and have been observed in the LAA. Bat species occur in the LAA, including at least one federally or provincially listed at-risk species (little brown myotis, <i>Myotis lucifagus</i>). Riverine birds (e.g., ducks, loons, grebes, murre, cormorants, geese, swans, and seagulls) have been identified as culturally important to Aboriginal Groups. |
| Mammals | Trowbridge’s shrew, southern red-backed vole, <i>occidentalis</i> subspecies, Olympic shrew, and Pacific water shrew are provincially listed (Red or Blue) and are considered potentially present within the Project alignment. Pacific water shrew is an identified wildlife species under the <i>Forest and Range Practices Act</i> (FRPA), S.B.C. 2002, c. 69 and is federally listed. River otter (<i>Lontra canadensis</i>) was identified as a species that is culturally important to Aboriginal Groups during consultation activities and is included for assessment. |

4.8.1.3 Indicators

Habitat loss, sensory disturbance, and collision risk were used as indicators to assess trends of terrestrial wildlife within the assessment area and evaluate potential Project-related effects.

Table 4.8-2 presents the indicators chosen for the assessment of Project-related effects on the three terrestrial wildlife sub-components, and the rationale for their selection.

Table 4.8-2 Indicators for the Terrestrial Wildlife VC

| Sub-component | Indicators | Rationale for Selection |
|---|--|---|
| Upland birds, riverine birds and bats, and mammals | Habitat loss: Amount and quality of foraging or breeding habitat that overlaps with Project components | The area of lost habitat, and anticipated reductions to its quality, is quantification of potential Project-related changes to foraging and/or breeding for upland birds, riverine birds and bats, and mammals. |
| Upland birds, riverine birds and bats, and mammals | Sensory disturbance: Changes to usability of foraging or breeding habitat within the Project alignment | Access to usable foraging and breeding habitat affects the distribution and abundance of upland birds, riverine birds and bats, and mammals. |
| Upland birds, riverine birds and bats, and mammals. | Collision mortality: Risk of mortality | Mortality affects population size and sustainability; a qualitative assessment of mortality due to vehicle collisions with wildlife, and collisions with the bridge for upland birds and riverine birds and bats. |

4.8.1.4 Assessment Boundaries

The assessment boundaries for terrestrial wildlife are defined below.

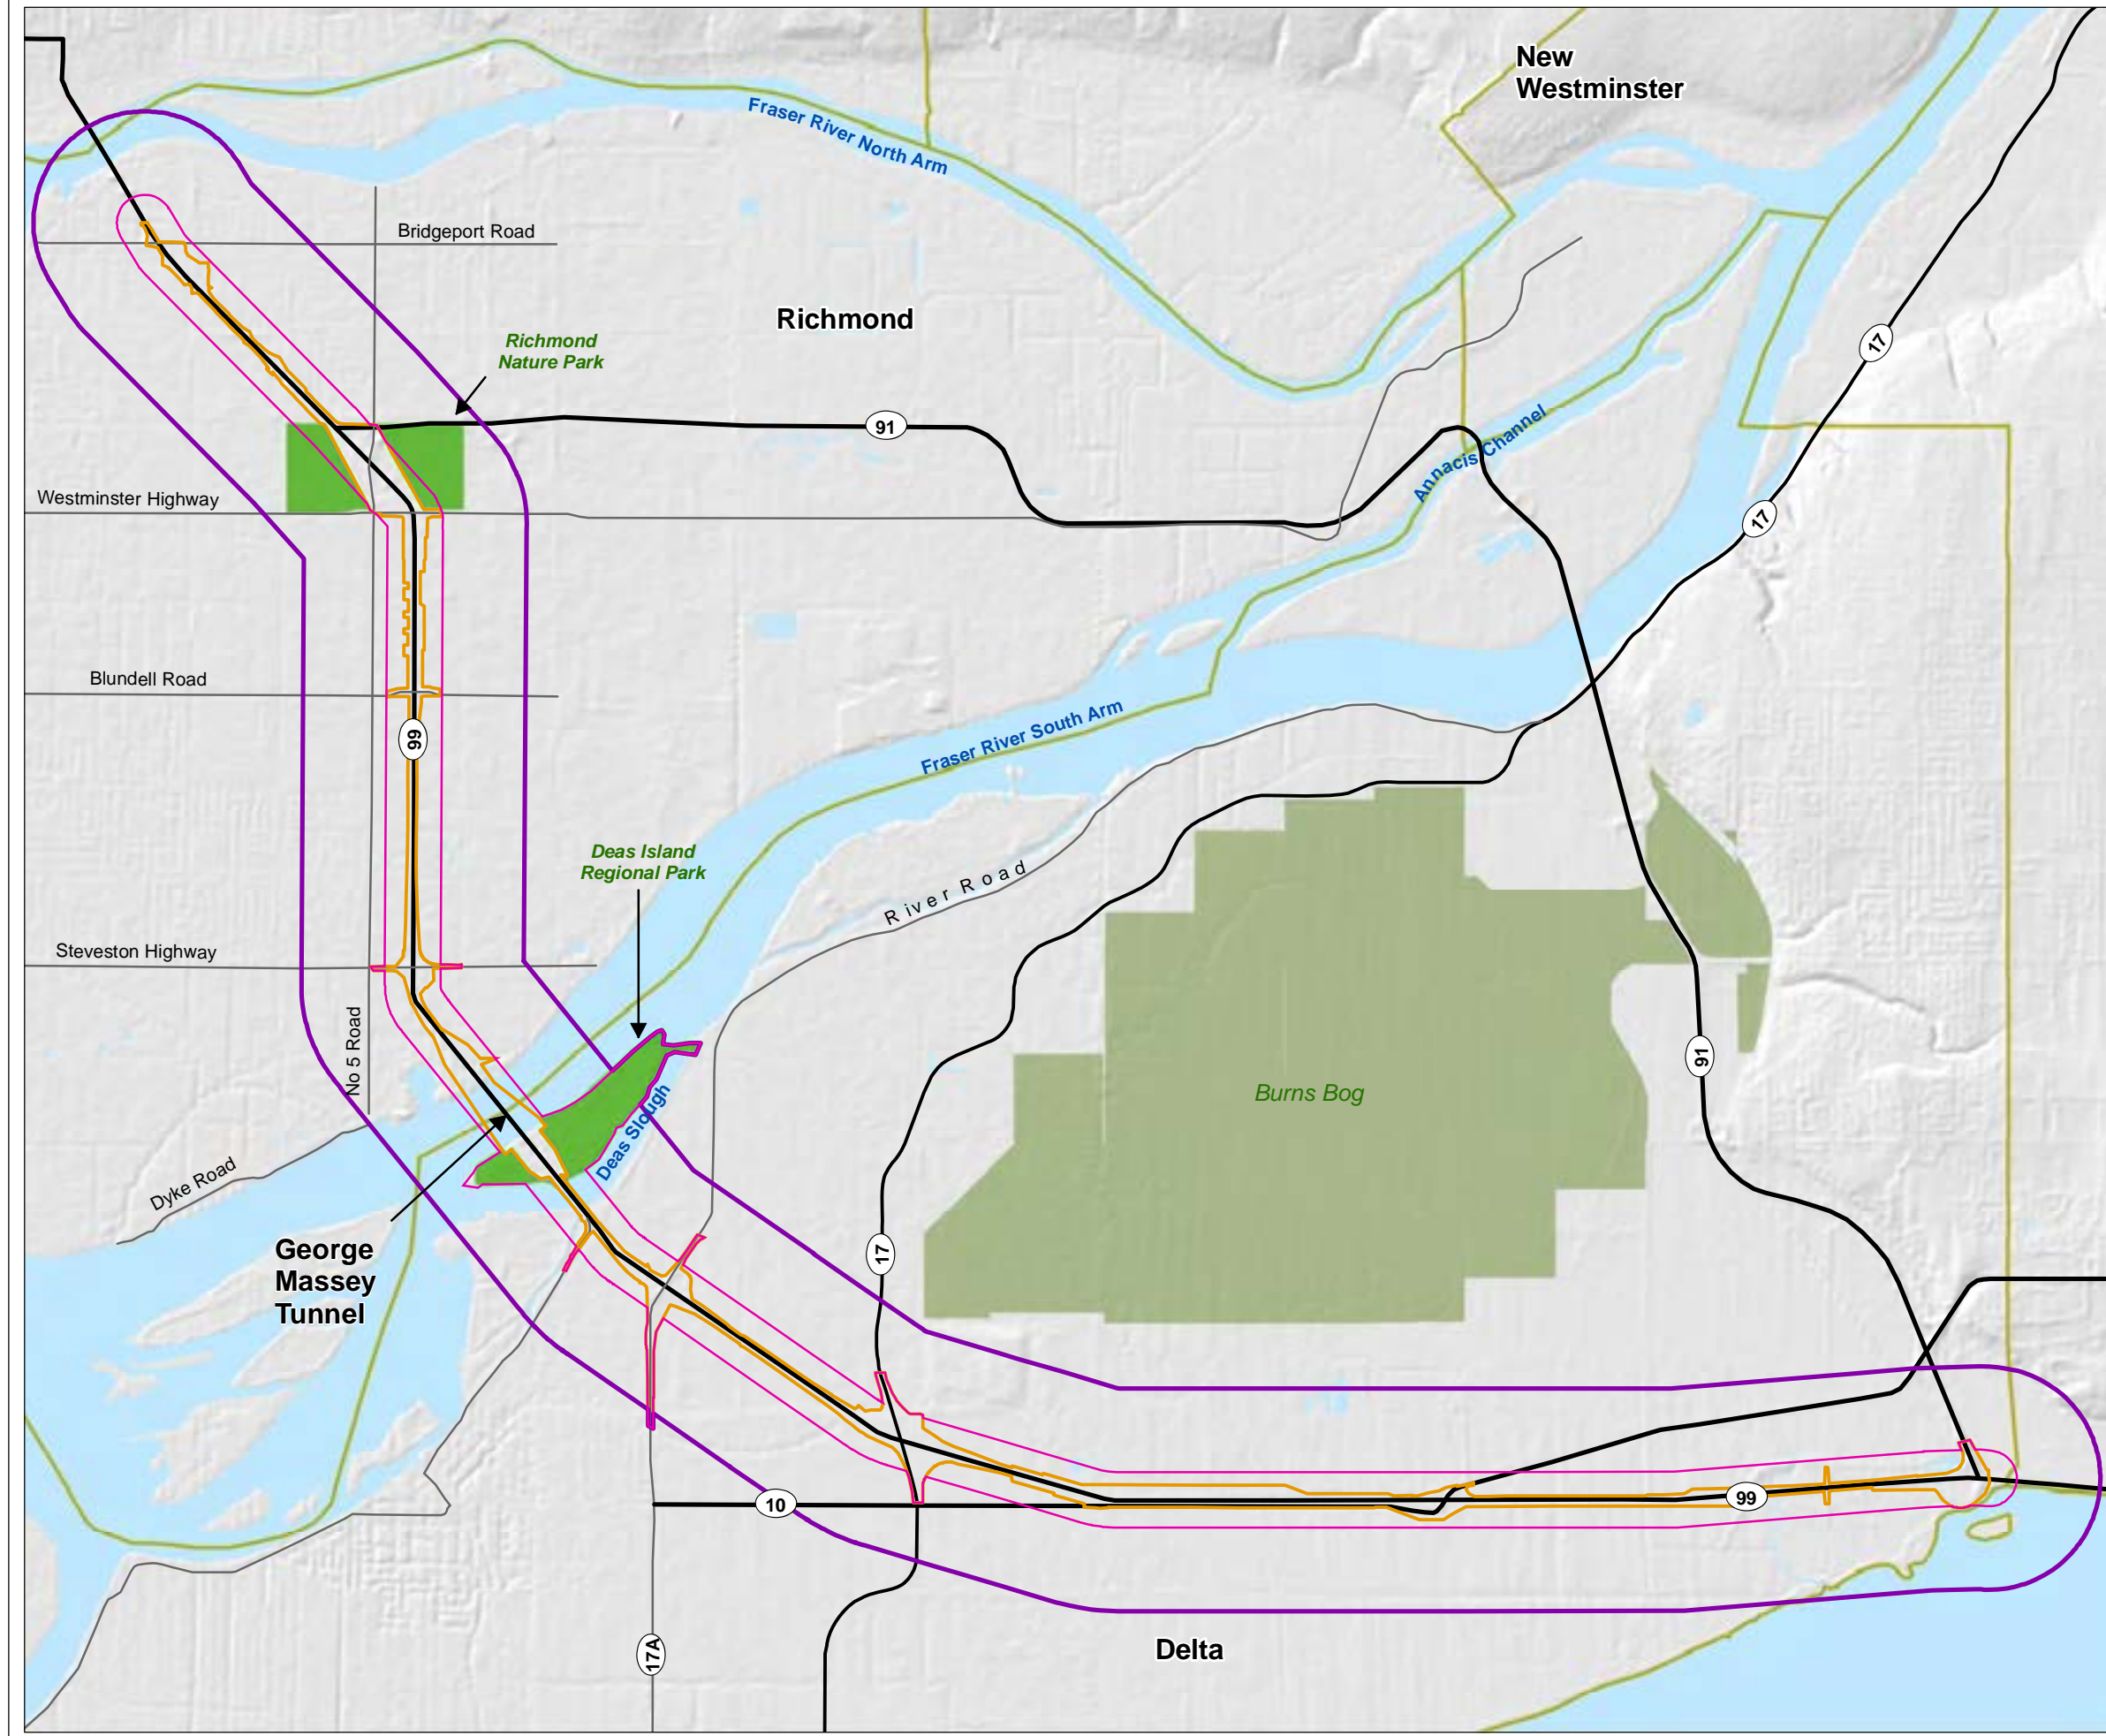

Spatial Boundaries

The LAA and RAA for terrestrial wildlife (**Table 4.8-3** and **Figure 4.8-1**) take into account the scale and spatial extent of potential environmental effects appropriate for the three sub-components.

The LAA encompasses the area within which the Project is expected to interact with and potentially affect terrestrial and semi-aquatic wildlife. In determining LAA boundaries, consideration was given to the nature and characteristics (i.e., sensitivities) of terrestrial wildlife, their potential exposure to various influences (e.g., habitat loss, traffic, infrastructure), and the maximum geographic extent of potential adverse effects on terrestrial and semi-aquatic wildlife given the existing environment. The RAA was established to provide a regional context for the assessment of Project effects.

Table 4.8-3 Spatial boundary definitions for terrestrial wildlife

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|---|
| Local assessment area (LAA) | Upland birds: Project alignment. Riverine birds and bats, and mammals: Project alignment plus 250 m on either side of the Highway 99 centreline, extending over the length of the Project. The area for all subcomponents is expanded in the vicinity of the new bridge to include Deas Island and Deas Slough, some of which extends beyond 250 m on either side of the highway. |
| Regional assessment area (RAA) | A 2 km wide corridor (1 km on either side of the Highway 99 centreline) over the length of the Project, and including all of Deas Island, part of which extends beyond 1000 m upstream of the Highway 99 centreline. |

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on terrestrial wildlife were established based on the potential for each phase of the Project to interact with and affect terrestrial wildlife. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, this includes both the construction and operational phases of the Project. The following temporal boundaries were defined for terrestrial wildlife assessment:

- Existing conditions
- Project construction (including Tunnel decommissioning)
- Project operation (including maintenance)

Temporal characteristics of the Project phases are discussed in **Section 1.0 Overview of the Proposed Project**. Specific temporal considerations for the assessment of terrestrial wildlife (e.g., nesting periods) are documented and considered in the existing conditions (**Section 4.8.2 Existing Conditions**), and Project interactions and potential Project-related effects (**Section 4.8.3 Potential Effects**).

Administrative Boundaries

No jurisdictional, economic, or social constraints that could limit the assessment of potential Project-related effects on wildlife have been identified; no administrative boundaries were identified.

Technical Boundaries

Constraints that could limit predictions of Project-related effects on wildlife have been identified. Such limitations are standard in biology impact assessment and relate to the absence of a full-knowledge of species and their distributions and the representative sampling that is implicit and commonplace in biological surveys. Predictive modelling is also used and such methods incorporate assumptions. Most of the methods used are supported by government-sponsored documentation that suggests they are standard procedures for surveying and sampling. These technical boundaries are not considered to limit the predictions.

4.8.2 Existing Conditions

This section provides an overview of the methods for collecting baseline data, and describes the existing wildlife conditions in the assessment areas. An overview of the regulatory context for management of wildlife relevant to the Project is also provided.

4.8.2.1 Baseline Data Collection

In 2014, the Ministry initiated studies on terrestrial wildlife to support Project planning and environmental assessment (**Table 4.8-4**). These studies were designed to augment existing knowledge and address known data gaps.

Table 4.8-4 Terrestrial Wildlife Studies

| Study Name | Purpose of Study |
|--|--|
| Upland Birds | |
| Barn owl habitat suitability assessment | Determine suitability of the LAA as foraging habitat for barn owl by assigning habitat suitability rankings. |
| Raptor and heron surveys | Document the presence of conspicuous raptors and herons and nest activity in the LAA in spring, summer, autumn, and winter. |
| Songbird surveys | Establish species presence in areas proposed for clearing or construction using point count methods. |
| Common nighthawk call-playback surveys | Establish baseline data for common nighthawk in the Project alignment (Deas Island only) using call-playback methods. |
| Structure survey for nesting swallows | Map presence of swallow nests in structures that would be removed or altered during Project construction. |
| Riverine Birds and Bats | |
| Marsh bird call-playback surveys | Identify marsh bird species presence in areas proposed for clearing or construction using call-playback methods. |
| Radar, standwatch, and ultrasonic acoustic surveys for riverine birds and bats | Identify collision risk for avian and bat species relative to the new bridge and associated infrastructure. |
| Mammals | |
| Small mammal habitat suitability modelling | Determine the ability of habitat in the LAA to provide life requisites for small mammal focal species using habitat suitability modelling. |
| Pacific water shrew eDNA studies | Establish presence/not detected status of Pacific water shrew in the LAA using eDNA sampling. |
| River otter assessment | Establish presence of river otter in the LAA and assess late-spring (breeding period) use and activity using meander transect survey methods to identify active latrines (river otter high-use areas). |

Studies for Upland Birds

Barn Owl Habitat Suitability Assessment

Barn owl (*Tyto alba*) are not known to nest in, or immediately adjacent to, the Project alignment. Accordingly barn owl studies in the LAA focussed on modelling suitable foraging habitat in accordance with provincial standards (RIC 1999a). Habitat suitability ratings were assigned to ecosystem units defined in the terrestrial ecosystem mapping (TEM; **Section 4.7 Vegetation Assessment**). A four-class rating scheme (i.e., high, moderate, low, nil) was used, based on each unit's potential to provide barn owl foraging requisites (i.e., habitat suitable for Townsend's vole, *Microtus townsendii*) within 250 m of the Highway 99 centreline. The values for each ecosystem unit were analyzed and mapped to create a barn owl habitat suitability model.

Raptor and Heron Surveys

Roadside surveys were conducted to document raptor and heron species in the LAA. A total of 16 surveys (four surveys per season) were conducted in 2014, following methods adapted from the *Inventory Methods for Raptors* (RIC 2001). For each survey, two driving transects (one in each direction) along Highway 99 were completed. The methods employed adhered to the standards with the exception of not exceeding a vehicular speed of 40 km/hr. Driving transects were conducted at approximately 60 km/hr, which allowed the surveyors to effectively search for raptors and herons while travelling safely on Highway 99.

The location of each bird observed, the species, age and sex (if possible), behaviour (perching, standing, or flying), and the perpendicular distance from the highway were recorded. Agricultural areas were scanned from a vehicle, and treed areas near the Tunnel and on Deas Island were surveyed on foot. For each nest detected, the location, condition, activity level, substrate, and species were recorded.

Songbird Surveys

Point counts (visual and aural observations) were conducted at 15 stations in the LAA in accordance with provincial standards to establish species presence (RIC 1999b), with the exception that standards recommend point counts of five-minute duration, but a 10-minute duration was used because high noise levels associated with existing Highway 99 traffic interfered with bird detectability. Bird detections were classified within or beyond a 50-m radius of each station. Nine point count stations in the LAA were surveyed three times: May 2015, June 2015, and May 2016. One point count station was added in June 2015 and only surveyed once. Five additional point count stations were surveyed on Deas Island in May 2016.

Common Nighthawk Call-playback Surveys

Common nighthawk (*Chordeiles minor*) call-playback surveys were completed in accordance with provincial standards (RIC 1998a) in June 2015 at Deas Island to establish presence/not detected during the breeding period. Common nighthawk have been recorded infrequently at Deas Island (eBird 2015). Two call-playback surveys in mid- and late-June were conducted on a 3.5-km transect on Deas Island, based on historical presence in the area and potential for interaction with the Project.

Structure Survey for Nesting Swallows

Surveys for colonial nesting swallows using highway infrastructure for nesting were conducted in 2015 and 2016. All Highway 99 interchange and bridge structures, and the bridges on intersecting roads and railway lines, in the LAA were surveyed in winter or spring (January or May 2015). Those structures that had confirmed or possible use were re-surveyed in summer (June and July 2015). Presence of nests or nesting activity by barn (*Hirundo rustica*), cliff (*Petrochelidon pyrrhonota*), and northern rough-winged (*Stelgidopteryx serripennis*) swallow was documented. Incidental observations of other nesting species were also documented.

Studies for Riverine Birds and Bats

Marsh Bird Call-playback Surveys

The presence of wetland birds was surveyed in the only likely habitat for such species, Green Slough. Call-playback surveys to elicit responses from American bittern (*Botaurus lentiginosus*), Virginia rail (*Rallus limicola*), and sora (*Porzana carolina*) were conducted using standard survey techniques (Gibbs and Melvin 1993, RIC 1998b). Two surveys were during the peak breeding season (May 20 to July 10) to take advantage of enhanced detectability associated with territorial or nesting behaviours. To avoid replication (RIC 1998b), call-playback stations were spaced 250 m apart.

Radar, Stand-watch, and Ultrasonic Acoustic Surveys for Birds and Bats

Replacement of the Tunnel with a new bridge could result in new obstructions for avifauna. A collision risk study was conducted to understand seasonal use and behaviours by birds, and to estimate collision risk at the new bridge crossing location in the LAA. Studies of species present, and their flight patterns and behaviours (e.g., flight direction, flight height, obstacle avoidance reaction) were conducted in 2015 at the new bridge crossing location and at a reference site (Port Mann Bridge, which is of similar design to the Project). The study was conducted across four seasons (i.e., spring migration, breeding season, autumn migration,

early winter), representing four time periods with different bird species present and distinct behaviours for those species. Studies were conducted in the day (standwatch) and night (radar surveys), using approaches adapted from Environment Canada (2007) to accommodate the urban situation and the Project objectives.

Stand-watch surveys were conducted twice per site in each period, starting at or just before dawn, for four hours duration, and for approximately four hours preceding dusk on the same day. Data were summarized at the flock level rather than individual level to ensure sample independence. Each individual bird and all groups of birds flying together were considered a single flock observation.

During the spring and autumn survey periods, nocturnal radar surveys were conducted twice per site (eight total surveys). During radar surveys, two observers assessed bird and bat movement on vertical and horizontal axes from 30 minutes before sunset for three hours, and again from approximately 2.5 hours before dawn until 30 minutes after dawn. Radar surveys used two high-frequency marine radar units (Burger 2001, 2002). Concurrent ultrasonic bat call detection units (Echometer Touch) recorded, where possible, the species of bat that were observed on radar.

Potential risk of interaction with existing and proposed Project structures was categorized as:

- At risk: flight paths intersecting the projected bridge airspace
- Undetermined risk: flight path or behaviour indicating a potential interaction that the observer cannot confidently assess
- Not at risk: flight path not intersecting the projected bridge airspace

The heights used to determine this risk were:

- Port Mann Bridge min. 45 m, max. 160 m
- Proposed new bridge min. 60 m, max. 220 m

Collision risk at the reference site (Port Mann Bridge) was assessed by documenting obstacle avoidance behaviour categorized as follows:

- Collision: collision with structure
- Abrupt: avoidance reaction initiated within five metres of a structure
- Delayed: avoidance reaction initiated between 5 and 15 m from a structure
- Gradual: avoidance initiated more than 15 m from a structure
- None: no avoidance required, flying height maintained

Studies for Mammals

Small Mammal Habitat Suitability Modelling

Habitat suitability modelling was conducted to rate the available habitat in the LAA for providing the life requisites for small mammal species. The LAA was rated in accordance with provincial standards (RIC 1999a) for each focal species: southern red-backed vole, *occidentalis* subspecies (*Myodes gapperi occidentalis*), Olympic shrew (*Sorex rohweri*), Pacific water shrew and Trowbridge's shrew (*Sorex trowbridgii*). Habitat ratings for each species were assigned to ecosystem units identified in the TEM (**Section 4.7 Vegetation Assessment**). The ratings were based on the ability of each unit to provide the life requisites for each species. Information for Pacific water shrew, and Trowbridge's shrew allowed the use of a four-class rating scheme (i.e., high, moderate, low, or nil habitat value). Limited information for southern red-backed vole, *occidentalis* subspecies and Olympic shrew only allowed for the use of a two-class rating scheme (i.e., habitat useable, or likely of no value). The values for each ecosystem unit were analyzed and mapped using GIS software to create species-specific habitat suitability models.

Pacific Water Shrew Environmental DNA Study

Environmental DNA (eDNA) studies were conducted in sites with suitable habitat within the footprint to detect presence of Pacific water shrew (**Appendix B, Figures 1a to 1c**). This method samples water features used by Pacific water shrew to search for shed genetic material (i.e., DNA) such as feces, exfoliation, mucus, and urine. Three sites in the LAA were deemed suitable habitat for Pacific water shrew, and were sampled on May 28 and 30, 2014, a time of year when Pacific water shrew actively forage in water. One sample at Fergus Creek in Surrey (with 12 replicates) was also collected. While outside the study area, this is a location where Pacific water shrew is historically known to occur (B.C. CDC 2008) and served as a reference site. Environmental DNA sampling methods followed a modified¹ standard eDNA protocol (Goldberg and Strickler 2013) to address the specifics of the species under study. Details on eDNA methods (identical to the proposed RISC standard) are provided in **Section 4.5 At-Risk Amphibian Assessment**.

River Otter Assessment

Meander transect surveys were conducted in April 2016, by boat and on foot, to assess river otter use of riverine and riparian habitats within the Fraser River portion of the LAA and RAA. Evidence of use focussed on latrine sites. At each latrine site photographs were taken of scat

¹ Minor modifications to the pump and other equipment did not influence the validity of the process or results.

and sign (tracks, trails and borrow/den entrances) to document species use, sign abundance, and habitat values. Search intensity was focused on areas of perceived high and moderate habitat potential (i.e., steep complex rip-rap shorelines with riparian forest). The methods followed recommendations from researchers in the USA and BC (Cait Nelson and Kim Sagar *pers. comm.*) and used modified provincial standard data forms to accommodate river otter specifics (RIC 1998c).

4.8.2.2 Regulatory Context

Terrestrial wildlife in B.C. is protected under federal and provincial legislation. Management of wildlife and wildlife habitat is the responsibility of provincial and federal regulatory agencies, including the B.C. Ministry of Forests, Lands and Natural Resource Operations (MFLNRO), and Environment Canada – Canadian Wildlife Service (CWS).

Regulation and management of terrestrial wildlife occurs primarily through:

- The federal *Species at Risk Act* (SARA), S.C. 2002, c. 29
- The federal *Migratory Birds Convention Act* (MBCA), S.C. 1994, c. 22
- The B.C. *Wildlife Act*, R.S.B.C. 1996, c. 488
- The B.C. *Forest and Range Practices Act* (FRPA), S.B.C. 2002, c. 69

The Committee on the Status of Endangered Wildlife in Canada (COSEWIC) and the B.C. Conservation Data Centre (CDC) assess, designate, and recommend species at risk for protection under the SARA and the *Wildlife Act*, respectively.

Federal

The SARA protects species, subspecies, and distinct populations listed on Schedule 1 of the SARA as endangered, threatened or extirpated. Species listed on Schedule 1 are afforded protection by the SARA on federal lands where critical habitat has been identified in a recovery strategy or action plan. There is no federal land or critical habitat within the Project alignment.

The federal MBCA regulates human activities that may be harmful to migratory birds, protecting species (and their eggs and nests) that are listed under Occasional Paper No. 1 (CWS 1991) on all federal, provincial, and private land. Raptors are not protected by the MBCA.

Provincial

In B.C., wildlife² are protected from direct harm, except as allowed by regulation (e.g. hunting or trapping) by the provincial *Wildlife Act*. The *Wildlife Act* extends to virtually all vertebrate animals, including raptor species not protected under the MBCA. Any vertebrate other than fish can be legally designated as endangered or threatened under the *Wildlife Act*.

Habitat protection is offered to specific species under the provincial FRPA through the Identified Wildlife Management Strategy. This strategy guides the establishment of Wildlife Habitat Areas (WHA) and general wildlife measures for species at risk.

4.8.2.3 Existing Conditions

This section describes existing conditions of terrestrial wildlife in the LAA and surrounding environment, and factors influencing terrestrial wildlife.

Aboriginal Groups have identified traditional use of terrestrial wildlife in the LAA, including the harvesting of waterfowl and mammal species. The South Arm of the Fraser River was a prime spot for hunting waterfowl and trapping American beaver, American mink, river otter, and common muskrat. Grouse were hunted in the open fields of Lulu Island. Deer and bear have been taken at Burns Bog within living memory, and American beaver and bear are said to have been taken at the heads of the Serpentine and Nicomekl rivers. Consistent and long-term trend monitoring of wildlife is not conducted by governments in the RAA. A small number of species and or discrete locations have had dedicated one-off sampling conducted (i.e., for species at risk inventory). The majority of current projects and activities in the RAA that affect terrestrial wildlife VCs are not required to monitor and report on their effects (Highway 17 data used in this assessment is one exception). While localized parts of the RAA have some monitoring for one or two of the VCs, (e.g., Christmas Bird Counts, wildlife collision impacts on highways, and Delta Farm and Wildlife Trust effectiveness monitoring), collectively these efforts are limited and insufficient to establish an ecological trend for terrestrial wildlife VCs.

Despite the absence of long-term trend monitoring, it is clear that species that are present in the Project alignment are tolerant of or adaptable to the effects of the existing highway, agriculture, and urban development. These species tolerate the existing activities, and in some cases utilise project footprints for day to day or seasonal life requisites. For example; great-blue heron use of highway ditches, and red-tailed hawk foraging in highway rights-of-way). Species that are not tolerant of such activity, and were intolerant of the historical conversion of the study area to

² Except “controlled alien species”, plants and invertebrates as defined by the *Wildlife Act*.

agriculture, are largely absent. Barn owl was likely not present in the study area before about the 1930s when large-scale agricultural conversion created open farm fields and barns suitable for establishment of a population in the Lower Mainland.

Current trends in species presence based on professional judgement and inference from previous monitoring suggests mostly stable to increasing populations for those species that are present (esp. raptors such as bald eagle and red-tailed hawk). Habitat availability and the trend toward cranberry and blueberry crops versus vegetable crops and hedgerow removal has a large influence on wildlife presence. The Delta Farm and Wildlife Trust's efforts in creating medium-term set-asides for wildlife and hedgerows have had a positive influence. Exceptions to that general rule of population stability include barn owl, for which barn demolition and highway mortality have a negative influence, and aerial insectivorous birds (i.e., swallows) which are understood to be facing continent-wide declines (Environment Canada 2012).

Upland Birds

Barn Owl

Barn owl presence in the Lower Mainland is limited to agricultural areas. The highest known barn owl densities in the Lower Mainland occur in agricultural lands of southwest Delta (Campbell et al. 1990a).

Barn owl generally forage in open fields, grasslands, and agricultural areas where they prey almost exclusively on small mammals, particularly Townsend's vole (CDC 2015). In the Lower Mainland, barn owl habitat is positively correlated with habitat suitable for Townsend's vole, and includes moist fields and sedge meadows (Campbell et.al. 1987). Townsend's vole are common in fields, especially less-disturbed ones, in and adjacent to the LAA (Hemmera 2013a).

Barn owl typically breed from April through August, but with abundant food and warm weather may nest outside this period (COSEWIC 2010). Availability and use of nest and roost sites in southwest Delta has remained relatively consistent since 1990 (Andrusiak 1994, Hemmera 2013b). Barn owl nest and roost mainly in man-made structures such as barns, silos, and industrial buildings. Nesting was documented in 2014 on the steel substructure supporting the old Port Mann Bridge (Hagmeier 2014). During 2012 and 2013 field surveys conducted for the Highway 17 and the Roberts Bank Terminal 2 (RBT2) projects, collectively identified, 49 barn owl occupied sites were identified, of which 31 had evidence of breeding, seven were occupied but breeding was not confirmed, and 11 were identified as roost sites only (Hemmera 2014). No occupied nest sites have been identified in the LAA, but there are many in the RAA.

Based on the barn owl habitat suitability model, 15.7% (245.6 ha) of the LAA was estimated to provide moderate- to high-suitability foraging habitat for barn owl. Low-suitability foraging habitat comprised 48.8% (766.5 ha) of the LAA, whereas 35.5% (557.7 ha) was rated as nil-quality, offering no estimated foraging habitat for barn owl (Table 4.8-5; Appendix B, Figures 5b to 5p).

Table 4.8-5 Amount (in ha and % of LAA) of foraging barn owl habitat within each suitability rating class

| Life Requisite | Barn Owl | | | | | | | |
|---------------------------|----------|-----|----------|------|-------|------|-------|------|
| | High | | Moderate | | Low | | Nil | |
| | ha | % | ha | % | ha | % | ha | % |
| Living – Foraging Habitat | 39.7 | 2.5 | 205.8 | 13.1 | 766.5 | 48.8 | 557.7 | 35.5 |

Literature sources estimate the rate of mortality on high-use roads such as Highway 99 in agricultural areas at between 1.64 to 1.85 barn owl per km per year (Boves and Belthoff 2012, Bishop and Brogan 2013). Highway traffic exposure and the length of highways was shown to be the strongest predictor of collisions in a Lower Mainland study (Hindmarch et al. 2012). The collision risk is highest in highway segments through open pasture (Bond et al 2004, Moore and Mangel 1996).

Applying a median rate of 1.7 mortalities per km per year over the 11.5 km of concentrated barn owl habitat in the LAA (between Highway 17A and Highway 91 in Delta) translates to an estimated twenty mortalities per year in the LAA. Although barn owl mortality data along Highway 99 is not formally collected, incidental mortalities that confirm a current collision risk are regularly noted. Since 2010, three to seven mortalities per year have been noted in the LAA between Highway 17A and Highway 91 (S. Hindmarch and C. Palmer personal observation and non-systematic survey data). Mortalities on Highway 17 (SFPR) are monitored daily and, since monitoring started in late 2013, no barn owl mortalities have been reported along the section of Highway 17 that falls within 1km on either side of the Project alignment.

Raptors

The Fraser River delta is home to Canada’s highest concentration of wintering raptors, including bald eagle (*Haliaeetus leucocephalus*), rough-legged hawk (*Buteo lagopus*), red-tailed hawk (*Buteo jamaicensis*), and northern harrier (*Circus cyaneus*). In the winter there are winter resident species, overwintering species, and species that occur rarely or accidentally

(Butler and Campbell 1987). The open grassy verges and ditches of the Highway 99 right-of-way provide small mammal, amphibian, and minnow prey, which attract foraging raptors. Red-tailed hawk and bald eagle breed in the Lower Mainland, and can be observed along Highway 99 year-round. Trees and tall structures in and near the right-of-way provide nesting and perching sites for red-tailed hawk and bald eagle. Some raptor species, and possibly some individual raptors, have fidelity to nest sites, however nest site locations change from year to year. Most other raptor species are usually only present along Highway 99 in winter.

Studies undertaken in 2003 and 2004 for the South Fraser Perimeter Road (SFPR, Highway 17) documented 15 raptor species, including bald eagle, red-tailed hawk, northern harrier, American kestrel (*Falco sparverius*), peregrine falcon (*F. peregrinus*), and rough-legged hawk. In 2004, six raptor nests that belonged to either bald eagle or red-tailed hawk were identified in black cottonwood (*Populus trichocarpa*) or paper birch (*Betula papyrifera*) (B.C. MOTI 2006) near the bridge where Highway 17 traverses Highway 99.

During roadside surveys conducted for the Project in spring, summer, autumn, and winter 2014, raptor species observed along the Highway 99 corridor included bald eagle, red-tailed hawk, northern harrier, American kestrel, peregrine falcon, rough-legged hawk, and Cooper's hawk (*Accipiter cooperii*) (**Table 4.8-6; Appendix B, Figures 2a to 2d**). The most abundant species observed was bald eagle, followed by red-tailed hawk. Turkey vulture (*Cathartes aura*) was not detected in the LAA during the 2014 surveys; however, this species is likely present.

In spring, raptors were detected along most of Highway 99, but in greater concentrations near the Vancouver Landfill and Deas Slough. During summer, raptors were seen primarily near the landfill. No raptors were detected between Westminster Highway and the north end of the LAA in summer. In autumn, raptors were observed in low numbers (one to three detections) throughout the LAA except between Deas Slough and the west side of the Vancouver Landfill where no raptors were observed. Winter distribution was similar to spring, with raptors detected along most of Highway 99 with greatest concentrations near the Vancouver Landfill.

Nine raptor nests were identified in the LAA, including four nests that were confirmed to be active during the 2014 breeding season (**Table 4.8-7; Appendix B, Figure 3**). The activity of the five remaining nests was not determined, but no birds or signs of nesting activity were documented at these nest sites during spring or summer. Four nests were observed in the Project alignment. Of these, only one, a bald eagle nest adjacent to the Highway 91 / Highway 99 interchange, was confirmed to be active in 2014. A red-tailed hawk nest approximately 30 m from the alignment in Green Slough was also confirmed active in 2014 and 2015. Great horned owl nests are likely present in forested areas outside the study area (Delta Naturalists pers.comm.).

Active bald eagle nests are regularly present in Deas Island Regional Park. Aboriginal Groups have previously noted bald eagle breeding habitat along the Highway 99 corridor on Lulu Island. Elders have indicated that eagle numbers in the Richmond area have been declining.

Great Blue Heron

The Fraser River delta supports the largest winter resident great blue heron (*Ardea herodias* ssp. *fannini*) population in B.C (Campbell et al. 1990b). Herons forage in a variety of wetland habitats; including ditches and agricultural fields. In autumn and winter they roost alone or in small groups in coniferous trees, and in early spring (i.e., mid-March) breeding birds return to nesting colonies that are typically located in disturbance free mature coniferous and deciduous trees within eight kilometres of suitable foraging habitat (Campbell et al. 1990b). In the lower Fraser River, nest-building can begin as early as February (Butler and Baudin 2000, Vennesland 2004). There are no colonies in the LAA or RAA, but there is a large colony with several hundred nesting pairs in Tsawwassen (Delta Farmland and Wildlife Trust 2014).

During roadside surveys conducted for the Project in spring, summer, autumn, and winter 2014, 33 great blue herons were detected within the LAA (**Table 4.8-6; Appendix B, Figure 4**). The majority (18 total) were detected in the winter. Herons were most often seen adjacent to the stretch of Highway 99 that is closest to Boundary Bay. Very few herons were observed in areas where Highway 99 is bordered by residential or industrial development, though this is confirmed habitat for the species. No great blue heron nests were detected in the LAA (**Table 4.8-7**).

Table 4.8-6 Seasonal abundance of conspicuous raptors and herons in the LAA during 2014 roadside surveys

| Common Name | Scientific Name | Spring | | Summer | | Autumn | | Winter | |
|------------------------------|---------------------------------|------------|-----------|------------|-----------|-----------|-----------|------------|-----------|
| | | Count | Mean ± SD | Count | Mean ± SD | Count | Mean ± SD | Count | Mean ± SD |

| Unidentified raptor | - | 1 | <1 ± 1 | 3 | 1 ± 1 | 0 | - | 4 | 1 ± 2 |
| Great blue heron | <i>Ardea herodias fannini</i> | 6 | 2 ± 1 | 4 | 1 ± 1 | 5 | 1 ± 1 | 18 | 5 ± 3 |
| Total count by season | | 683 | | 216 | | 28 | | 229 | |

Note: Count is the total detections per season.
 Mean is the mean count by season (four surveys per season) plus or minus the standard deviation (SD).

Table 4.8-7 Raptor nests observed in the LAA

| Nest ID | Species | Structure | General Area | Distance from Alignment (m) | Activity Status ¹ |
|---------|---------------------|------------------|---|-----------------------------|------------------------------|
| 01 | Unidentified raptor | Black cottonwood | North side of the Tunnel | 9 | Unknown |
| 02 | Red-tailed hawk | Black cottonwood | Forest near the Hwy 99 S-bound off-ramp to River Rd | 33 | Active |
| 03 | Bald eagle | Black cottonwood | Deas Island | 869 | Active |
| 04 | Bald eagle | Black cottonwood | Deas Island | 255 | Active |
| 05 | Unidentified raptor | Black cottonwood | South of Westminster Hwy | Within alignment | Unknown |
| 07 | Unidentified raptor | Deciduous tree | Golf course | 606 | Active |
| 08 | Bald eagle | Deciduous tree | NW side of Highway 91 / Highway 99 interchange | Within alignment | Active |
| 09 | Bald eagle | Deciduous tree | South of Vancouver Landfill, near 88 Street | 294 | Active |
| 10 | Unidentified raptor | Deciduous tree | South of Vancouver Landfill, near 88 Street | Within alignment | Unknown |
| 11 | Unidentified raptor | Black cottonwood | Highway 17 on-ramp to Highway 99 southbound | Within alignment | Unknown |
| 12 | Bald eagle | Deciduous tree | Near Highway 17 on-ramp to Highway 99 southbound | 172 | Active |
| 13 | Unidentified raptor | Black cottonwood | Near Highway 17 and Ladner Trunk Road | 64 | Unknown |
| 14 | Red-tailed hawk | Black poplar | Golf course north of Steveston Highway | 54 | Active |

Note: ¹ Activity status was determined based on bird presence or signs of nesting observed during summer 2014 surveys.

Songbirds

The Fraser River delta is an important feeding and resting stop for migratory birds travelling along the Pacific Flyway (FREMP 2003). Bird surveys conducted for Highway 17 (SFPR) in 2003 and 2004 documented 62 passerine species in terrestrial habitats along the 40 km-long Highway 17 corridor (B.C. MOTI 2006), a small part of which overlaps with the LAA. Monitoring for Highway 17 (2009-2014) shows 42 species in the closest sampling stations to the LAA; the majority of bird species detected are considered common occurrences in the Lower Mainland. Only two listed species were detected at these stations: barn owl and barn swallow. In farm fields the most abundant songbird species accounting for nearly 92% of total observations were European starling (*Sturnus vulgaris*), savannah sparrow (*Passerculus sandwichensis*), barn swallow, American robin (*Turdus migratorius*), and house sparrow (*Passer domesticus*). During songbird surveys conducted in 2015 and 2016 for the Project, 39 species were detected at the survey stations (Table 4.8-8). All species observed were common birds of developed locations in the Lower Mainland. Caspian tern (*Hydroprogne caspia*) is a provincially blue-listed species, the only federally or provincially listed species at risk observed flying over the Project area during songbird surveys.

Table 4.8-8 Bird species observed during songbird bird surveys conducted in the LAA (spring and summer 2015 and spring 2016)

| Songbird species in the LAA | | |
|-----------------------------|------------------------|--------------------------|
| American goldfinch | Common yellowthroat | Pacific-slope flycatcher |
| American robin | Dark-eyed junco | Pine siskin |
| Anna's hummingbird | Downy woodpecker | Red-winged blackbird |
| Bald eagle | Eurasian-collared dove | Rufous hummingbird |
| Bewick's wren | European starling | Song sparrow |
| Black-capped chickadee | House finch | Spotted towhee |
| Black-headed grosbeak | House sparrow | Swainson's thrush |
| Brown creeper | Marsh wren | Violet-green swallow |
| Brown-headed cowbird | Mourning dove | Western wood-pewee |
| Bushtit | Northern flicker | White-crowned sparrow |
| Caspian tern | Northwestern crow | Willow flycatcher |
| Cedar waxwing | Orange-crowned warbler | Yellow warbler |
| Chipping sparrow | Pacific wren | Yellow-rumped warbler |

Across Canada, approximately 35 birds per kilometre of road are estimated killed during the breeding and fledging season due to vehicle collisions; mostly these are perching songbirds and owls (Bishop and Brogan 2013). For upland birds, changes to Highway 99 are not expected to markedly alter the level of effects over those currently seen. Traffic volumes are currently high, and will stay high with or without the Project.

Common Nighthawk

Common nighthawk have been infrequently observed within the LAA and RAA (eBird 2015). Between 1985 and 2013, eight sightings have been documented in the RAA, seven in the LAA, all on or near Deas Island. Two surveys at Deas Island in June 2015 did not find any evidence of presence or breeding. Due to the infrequent observations of this species, and the absence during species-specific surveys, it is concluded that common nighthawk is an infrequent visitor to the Project alignment and, as such, is not considered further in this assessment. Quality breeding habitat for common nighthawk is un-vegetated areas in open situations.

Swallows

Three swallow species (tree swallow (*Tachycineta bicolor*), violet-green swallow (*T. thalassina*), and barn swallow) commonly occur during the summer in Delta and Richmond. Cliff swallow are uncommon, while northern rough-winged swallow, and bank swallow (*Riparia riparia*) are rare visitors (Campbell et al. 1997). Of these, cliff swallow and barn swallow, which typically nest in mud nests attached to buildings, cliffs, and bridges, are of interest. Three occupied barn swallow nests and a single cliff swallow nest were observed beneath the Deas Slough Bridge on May 14, 2014. During follow-up surveys in spring and summer 2015, 13 barn swallow nests and three cliff swallow nests were observed under the Deas Slough Bridge, and barn swallow nesting activity was documented. Nesting activity was detected on other infrastructure near the LAA (e.g., boathouses, barns, building eaves). The cliff swallow nests were not observed to be active, and no cliff swallows were noted. Nine to 15 barn swallows were observed during the surveys. On July 16, 2015 two fledgling barn swallows were observed. Quality breeding habitat varies among swallow species, key for consideration in this project are cliff / structure nesting species which variously require clay or other banks for their cavities, or mud to build nests on vertical structures (natural or man-made).

Riverine Birds and Bats

Marsh Birds

During marsh bird surveys conducted at Green Slough in May and June 2015, no bittern, rail, or sora were detected. While reasonable habitat appears to be present, it is neither large in extent nor free of nearby disturbances; a general requirement for these species.

Riverine Birds and Bats

Based on results from radar and stand-watch surveys in May 2015, bird diversity and abundance were greater at the Project’s proposed bridge crossing (LAA) relative to the Port Mann Bridge reference site (**Table 4.8-9**).

Table 4.8-9 Bird diversity and abundance day (stand-watch) and night (radar) in the new bridge crossing portion of the LAA and the Port Mann reference site

| Site | Day/night | Diversity and Abundance |
|----------------|-----------|---|
| LAA | Day | 58 species, 1,598 flocks, and approximately 7,736 individuals recorded. |
| | Night | 3,925 on horizontal radar and 4,792 on vertical radar. |
| Reference site | Day | 43 species, 748 flocks, and approximately 3,267 individuals recorded. |
| | Night | 2,297 on horizontal radar and 1,808 on vertical radar. |

At the new bridge crossing site in the LAA, more nighttime-active birds were observed on vertical radar flying at elevations that could intersect with the proposed bridge structure (60 - 220 m) than those above or below and therefore not intersecting (**Figure 4.8-2**). However, swallows (violet-green, barn, and tree swallow), and pigeons (in “other”) comprised the majority (>71%) of the intersecting birds, and these species are not considered at any collision risk because they use structures for nesting and roosting. At the Port Mann reference site there were very few birds in the interaction zone (45 - 160 m), most were above, some were below (**Figure 4.8-2**). This avoidance is likely a result of learned behavior and observation.

During the daytime, less than a third of flocks observed were flying in the interaction zone at the proposed new bridge crossing site in the LAA (**Table 4.8-10**). Many in the interaction zone were species not considered at risk of impact because they regularly use structures for nesting and roosting; pigeons, swallows and cormorants (part of the diving waterbirds group).

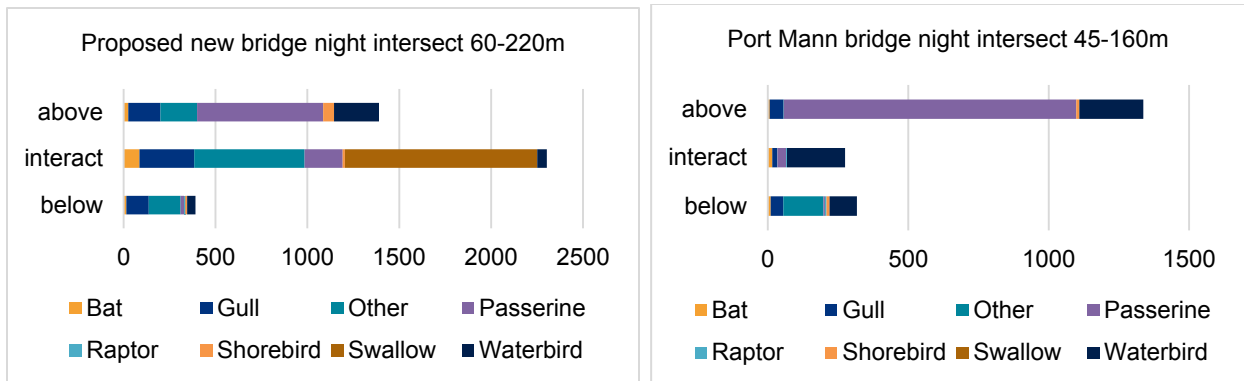

Figure 4.8-2 Nighttime bat and bird flight heights relative to proposed bridge infrastructure in the LAA and at existing infrastructure at the Port Mann reference site.

Table 4.8-10 Proportions of species group flocks in the potential interaction zone (height and trajectory) at the new bridge crossing in the LAA.

| Species Group | No. of flocks | % of flocks flying at 60-220 m |
|----------------------------|---------------|--------------------------------|
| Cranes | 2 | 100% |
| Crows, Jays, and Ravens | 67 | 46% |
| Dabbling Waterbirds | 35 | 64% |
| Diving Waterbirds | 13 | 18% |
| Geese | 6 | 30% |
| Gulls and Terns | 186 | 23% |
| Hérons and Bitterns | 10 | 29% |
| Kingfishers | | 0% |
| Pigeons and Doves | 22 | 51% |
| Raptors | 26 | 42% |
| Shorebirds | 9 | 43% |
| Songbirds and Hummingbirds | 10 | 27% |
| Swallows and Nighthawks | 15 | 31% |
| Swans | 0 | 0% |
| Woodpeckers | 0 | 0% |
| Total | 401 | 29% |

The behaviours of birds at the Port Mann reference site was noted during day and night surveys, however the daytime observations provided more reliable data. Most birds appeared to be aware of the bridge structure either flying above or below it, or exhibiting planned or gradual avoidance flight paths (**Figure 4.8-3**). Collisions were rare, and only a small number, under 10%, exhibited abrupt or delayed avoidance behaviours that suggested a lack of awareness of the structure.

Figure 4.8-3 Seasonal avoidance behaviours exhibited by bird flocks (daytime) at the Port Mann reference site.

Seven at risk species were observed during the diurnal standwatch and nocturnal radar studies; great-blue heron, California gull (*Larus californicus*), Caspian tern (*Sterna caspia*), barn owl, barn swallow, double-crested cormorant (*Phalacrocorax auritus*) and common nighthawk. Aside from barn swallows which were often in flocks of multiple birds, most of the observations were individual birds. Except for barn swallow, most of the observations were above or below the interaction zone for existing or proposed new structures.

- Barn swallow; 30 flocks all at the Project site, multiple observations in the flocks (up to 25 individuals), just over half the individuals in the interaction zone for proposed structures.
- Barn owl; one individual at the project site and below the interaction zone of proposed structures.
- California gull; 13 flocks, all single bird observations except a flock of 14, half at the reference site, half at the new bridge crossing site, only two individuals in the interaction zone of the current structures.

- Caspian tern, eight flocks, mostly single bird observations, half at the reference site, half at the project site, mostly below the interaction zone for current or proposed structures.
- Great-blue heron; 92 flocks, mostly single bird observations, half at the reference site, half at the project site, ~70% below the current or proposed structures.
- Common nighthawk; one individual at the project site and below the interaction zone of proposed structures.
- Double crested cormorant; 56 flocks, all in the day, and most (80%) outside of the interaction zone.

Spring and fall acoustic and radar sampling surveys (four nights and four morning surveys) confirmed bat presence around the proposed location of the new bridge. The evidence collected also indicated an absence of uncommon species, and suggested that interactions with the new bridge were likely to be minimal. The most common species present were Yuma and California myotis (*Myotis yumanensis* and *Myotis californicus* respectively). They were observed at, below, and above the proposed new bridge. Many of the below-bridge observations were at the river surface and difficult to detect on radar due to reflection. Bat activity at the surface of the Fraser River is likely more common than those at altitude, as evidenced by the ultrasonic call detection data and the common feeding practices of these species – both are over-water feeders predominantly focussed on caddisflies and mayflies. There is a Yuma myotis, and possibly little brown and California bat, maternity colony approximately 1 km from the Project alignment in Deas Island Regional Park. The large distance between the colony and the Project footprint, and the small potential for interaction in time indicates little potential for interaction with the colony. Bats are summer only and nighttime active. Because nighttime work will occur in areas of Deas Slough that are already well lit and noisy, characteristics that indicate low bat use (Fensome and Matthews 2016), no interactions are predicted.

Mammals

Small Mammals

Although approximately 83% of the LAA was mapped as sparsely or non-vegetated, and human-disturbed, these types of habitat (i.e., agricultural fields, roadside verges, hedgerows) support an assemblage of small mammals, including Townsend's vole, long-tailed vole (*Microtus longicaudus*), creeping vole (*M. oregoni*), deer mouse (*Peromyscus maniculatus*), and shrews such as common (*Sorex cinereus*), dusky (*S. monticolus*), and vagrant (*S. vagrans*) (B.C. CDC 2015a). Of these, Townsend's vole is the most abundant found in the old field, pasture, and grassy verge habitats common in the LAA (Hindmarch et al. 2012). This species is considered to be the highest value to the raptors, herons, and owls that forage in the area.

Based on habitat suitability modelling conducted for the Project, high and moderate suitability habitat for Trowbridge's shrew were four and six per cent, respectively (**Appendix B, Figures 6b to 6q**). Approximately nine per cent of the habitat in the LAA is rated as moderate suitability for Pacific water shrew; less than one per cent is high-rated habitat (**Appendix B, Figures 7b to 7q**). For southern red-backed vole (**Appendix B, Figures 8b to 8q**) and Olympic shrew (**Appendix B, Figures 9b to 9q**), 13 and nine per cent of the LAA for each species, respectively, is rated as usable habitat. Townsend's vole modelling is presented in the barn owl habitat section (above).

The most suitable Pacific water shrew habitats in the LAA are located in Richmond Nature Park, immediately south of the Vancouver Landfill, and north of Highway 99 between Highway 91 and the Delta Golf Club (**Appendix B, Figures 7b to 7q**). However, Pacific water shrew DNA was not detected at any of the surveyed locations, suggesting no occurrence of Pacific water shrew in these aquatic features at the time of the surveys or for up to three months previously. The lack of positive detections in this study prevented the calculation of detection probabilities using water chemistry data. There is no evidence that false positives were generated in the control samples, indicating that the procedures were effective at eliminating potential sources of contamination during collection, filtration and extraction methods.

River Otter

Meander transects were completed on April 12 (by boat) and April 13, 2016 (on foot). During 22.2 km of boat transects, river otter was observed three times in the same general location (2.1 and 0.8 km upstream of the proposed bridge location and 0.4 km downstream of the proposed bridge location). Land-based transects covered 9.1 km of riparian shoreline. During these two surveys, two latrine sites were noted within the Project alignment. One latrine was located in Green Slough, near the River Road off-ramp on the west side of Highway 99 within the proposed Project alignment. Evidence of use by river otter at this site appeared minimal; a beaver was also observed using this site. The second latrine was located on Fraser River rip-rap, adjacent to the north Tunnel portal (near the end of Rice Mill Road), on the east side of Highway 99. Sign of extensive use (feces) was noted at this latrine site.

In general, habitat in the survey area, characterized by gently sloping banks, grassy beaches and minimal security, is considered to be low-suitability river otter habitat. The areas where the two latrines were found contain a small amount of moderate-suitability habitat, characterized by steeper (or overhanging) banks, abundant coarse woody debris, and associated forested upland habitat.

4.8.2.4 Quality and Reliability of Data

Quality and reliability of the existing or baseline data and its applicability for the purpose used was rated as high, moderate, low, or nil, as defined below:

- High - data collected and analyzed using government-approved methods (e.g., RISC) and/or for the purpose of identifying or establishing trends in the VC under consideration. Includes modelling with field verification.
- Moderate - data collected and analyzed using established methods (e.g., biology best practices) and/or for the purpose of identifying or establishing trends in the VC under consideration. Includes two, four or six-scale modelling (RISC 1999a) without field verification.
- Low - data collected and analyzed using novel methods and/or for the purpose of identifying or establishing trends in species other than the VC but for which there are linkages or proxies that give predictive ability. Includes two-scale modelling.
- Nil - poor or unreliable data collection and analysis

The quality and reliability of the data collected and analysed for the wildlife VC are as follows:

- Upland birds:
 - Barn owl – Moderate. Four-scale modelling with no field verification (to avoid capture myopathy). Collision mortality based on Canada-wide and BC-specific rates that have error associated with searcher efficiency and scavenger effects.
 - Raptors – High. Government approved RISC methods used.
 - Great blue heron – High. Government approved RISC methods used.
 - Songbirds – High. Government approved RISC methods used. Note traffic noise affected detectability.
 - Swallows – Moderate. Established method for barn and cliff swallow nest counts as per RISC standard no. 16, modified for site and study-specific needs. Only high-potential sites were surveyed.
- Riverine birds and bats:
 - Marsh birds – High. Government approved RISC methods used.
 - Riverine birds and bats – High for daytime stand-watches, which is an Environment Canada approved collision-risk survey technique. Moderate for nighttime radar studies, which is a modified government approved survey technique for seabirds and collision-risk estimates. High for ultrasonic acoustic bat surveys, which used standard survey techniques.

- Small mammals:
 - Olympic shrew and southern red-backed vole, occidentalis subspecies – Low. Government-approved modelling techniques used although limited data available.
 - Pacific water shrew and Trowbridge’s shrew - Moderate. Government-approved modelling techniques used with moderate data availability.
 - River otter – High. Survey methods were developed in consultation with two published senior river otter biologists and field personnel included staff with previous river otter latrine survey experience.

4.8.3 Potential Effects

This section discusses anticipated interactions of Project components and activities with terrestrial wildlife, and potential effects of such interactions on upland birds, riverine birds and bats, and mammals. Concerns raised by Aboriginal Groups to the Ministry during consultation on the Project are addressed in this section, including concerns regarding availability of resources (see also **Section 10.1.3 Aboriginal Interests Assessment**). Information on mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 4.8.4 Mitigation Measures**. Potential residual effects (i.e., effects remaining following the implementation of mitigation) are described in **Section 4.8.5 Residual Effects and their Significance**. A discussion of potential cumulative effects on wildlife is presented in **Section 4.8.6 Cumulative Effects and their Significance**.

4.8.3.1 Project Interactions

An overview of potential interactions between Project activities and terrestrial wildlife during the construction and operation of Project components is provided in **Appendix A**. An evaluation of the potential effects of Project interactions on terrestrial wildlife, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Construction: Potential effects on terrestrial wildlife during Project construction (including pre-construction and site preparation) were of three types: habitat loss, habitat alteration (sensory disturbance and water quality), and direct mortality.

Loss of terrestrial wildlife habitat may occur as a result of clearing and grubbing for permanent and temporary Project-related infrastructure associated with highway widening and interchange upgrades, and installation of new bridge piers.

Habitat alteration may result from Project-related construction activity that elevates ambient noise levels (e.g., pile driving, ground improvements, demolition of existing infrastructure, construction of new infrastructure), or creates visual and olfactory stimuli (e.g., due to presence and movement of construction personnel, movement of machinery and equipment). These changes may result in sensory disturbance to terrestrial wildlife, creating sub-optimal habitat, or leading to temporary or permanent habitat abandonment.

Direct mortality of terrestrial wildlife might occur during vegetation clearing and grubbing, stripping, and soil excavation along Highway 99, as well as during decommissioning of the Deas Slough Bridge, and may result from:

- Destruction or failure of an active bird nest.
- Mortality of small mammals that inhabit woody debris, litter, and soil.

Operation: Potential effects on terrestrial wildlife during Project operation include traffic use of the reconfigured Highway 99 and associated interchanges, operation of the new bridge, and periodic maintenance of infrastructure leading to:

- Mortality of upland birds due to destruction of active nests during maintenance.
- Mortality of terrestrial wildlife as a result of collision with vehicles.
- Mortality of upland birds and riverine birds and bats as a result of collision with the new bridge.
- Habitat alteration – sensory disturbance due to changes in the light and noise environment associated with incremental traffic growth, new bridge operation, and water quality changes associated with ditch and watercourse alterations.

4.8.3.2 Potential Effects

Habitat Loss

Construction Phase

The area that will be occupied by Project components is small, and the available habitat for wildlife is dominated by highway road verges with generally low diversity and abundance. During field studies completed for the Project, 39 species of songbirds were recorded within the LAA. Diversity and abundance (abundance data not presented but available on request) of songbirds was noted to be low when compared to results of surveys associated with other recent Lower Mainland highway projects (e.g., Highway 17, where 62 species were detected). At some survey stations, less than 10 individual birds from only three species were recorded during point counts where upwards of 30 individuals from one species were recorded from point

count stations during Highway 17 follow-up monitoring (BC MOTI 2016). All species observed in the footprint of the Project were birds common in developed locations in the Lower Mainland. For most of the upland birds, riparian birds and bats, and mammals present, the reduction in habitat as a result of the Project is considered to be negligible. The habitat that could potentially be lost is sub-optimal and contains no unique elements required for populations, and other similar habitat is present nearby. For species using ditches (e.g., great-blue heron) the relocation of ditches is self-compensating, and habitat loss will be minimal. For the species present, the remaining habitat is considered sufficient to maintain populations. The rationale for this conclusion is summarized in **Table 4.8-11**.

Habitat loss effects on species groups assessed as negligible will not be considered further, except loss of nest sites for barn swallows (**Table 4.8-11**). During 2015 surveys conducted for the Project, barn swallow nests were detected under the Deas Slough Bridge. Decommissioning of the bridge will remove this habitat; however this will be done appropriately to avoid mortality if swallows are nesting during bridge removal. For these colonial, structure-nesting species, re-establishment of nesting at an alternate site is possible, if it is nearby and similar.

The Project is anticipated to result in a 0.75 ha reduction in highway verge and interchange interstitial habitat. This habitat is considered sub-optimal for foraging raptors, especially barn owl. These areas contribute to their risk of collision with vehicles and consequent population declines (traffic mortality). The infrequently disturbed grass with Townsend's vole and other small mammals attracts barn owl and other raptors (especially red-tailed hawk). Red-tailed hawk and other diurnal raptors generally appear to notice and avoid vehicles; however, barn owl behaviours frequently bring them into contact with vehicles while foraging in these areas. Highway widening and interchange development proposed as part of the Project will reduce the size of such risky, sub-optimal habitat characterized by areas that are attractive for foraging but prone to vehicle-related mortality (Hindmarch et al. 2012). Therefore, the anticipated reduction of this foraging habitat, where collision risk is high, is expected to result in a reduction in barn owl mortality.

Table 4.8-11 Rationale for characterization of habitat loss to terrestrial wildlife

| Species Group | Rationale | Nature of Effect |
|-------------------------|---|--|
| Barn owl | Reduction in sub-optimal habitat that enhances collision risk may reduce mortality. | Neutral |
| Raptors | Habitat loss is minor in the context of similar areas being available and its sub-optimal character. | Negligible |
| Great blue heron | Ditch relocation in advance of construction is included in Project design, and is self-compensating for habitat loss. | Negligible |
| Songbirds | Low diversity, sub-optimal habitat, low abundance. | Negligible |
| Swallows | No change to foraging habitat; potential loss of overall nesting habitat as a result of Deas Slough Bridge decommissioning. | Potential effect (carried forward in the assessment) |
| Marsh birds | None observed, and small habitat losses in Green Slough only, < 1 ha in total (5,707 m ² of instream and 1,654 m ² of riparian habitat). | Negligible |
| Riverine birds and bats | Habitat loss is minor in the context of similar areas being available and its sub-optimal character. | Negligible |
| Small mammals | Little high-rated habitat in the LAA for southern red-backed vole, <i>occidentalis</i> subspecies, Olympic shrew, Pacific water shrew and Trowbridge's shrew; areas where there is potential for loss of habitat is small. The proposed Project components overlap with 10% and 6% of habitat rated as Useable for southern red-backed vole, <i>occidentalis</i> subspecies, and Olympic shrew, respectively. There is 3% overlap with habitat rated as High for Trowbridge's shrew and no overlap with habitat rated as High for Pacific water shrew. | Negligible |
| River otter | River otter latrine sites near proposed bridge pier locations are not located in areas with unique habitat features, and river otter are not habitat-limited in the LAA. There is potential for temporary habitat loss at these precise locations, but the two latrine sites are likely to be reoccupied once construction is complete and habitat features are reestablished. | Negligible |

There is a 17.3 ha overlap between proposed Project components and ESA identified by the Corporation of Delta and City of Richmond. This overlap, most of which is in Richmond, is primarily within the Ministry's right-of-way that has been identified as ESA, and the rest, within private land. In Delta, a total of 0.28 ha overlap, on nine separate ESA, was identified. This is expected to be the result of minor overlaps and mapping anomalies between the boundaries of ESA and the adjacent Highway 99 right-of-way. Similarly, the overlaps for Metro Vancouver parks (Deas Island Regional Park) are very small and are likely an artifact of mapping inaccuracies. The Project alignment does not overlap with Burns Bog, an ESA that is cooperatively managed by municipal, regional, provincial, and federal governments.

There are potential interactions with 17 ESA in the City of Richmond (17.0 ha). The City of Richmond has established a five-scale priority ranking for conservation of their ESA, and all of the affected ESA are ranked at the lower end of the range, e.g., "3" to "5." These lower rankings are consistent with field observations that generally found the affected ESA to be (i) small isolated / non-connected ESA sites, or (ii) highway right-of-way areas on the periphery of an ESA. Refinements to the project alignment through the course of project have reduced the effects on ESA by approximately 50% (was 30.3 ha).

Operation Phase

Habitat losses during Project operation from maintenance activities have the potential for very minor effects to upland birds and mammals; this includes ditch clearing, bridge and structure cleaning and repair activities affecting foraging mammals, nesting songbirds, and raptors. The activities that lead to these effects will be similar in the future as they are currently, and as a result no additional effects are expected provided that the current standards and level of mitigation for maintenance activities is continued.

Once the Project becomes operational, bats will continue to find habitat available in the LAA, with only a very small portion (the portion close to the bridge deck lit by vehicles) of the airspace they currently use for foraging being unavailable. Bat foraging habitat will remain available above, below (especially at the Fraser River interface which has the highest recorded use currently), and adjacent to the new bridge. Other portions of the LAA will see no change in bat foraging activity when the Project is in operations as it is not appreciably different in nighttime noise and activity levels to that currently experienced. Further, no suitable roosting habitat (i.e., trees) adjacent to the Project alignment is affected by the Project.

Habitat Alteration (Sensory Disturbance and Water Quality)

Construction Phase

Construction noise might affect wildlife using the Project alignment by forcing abandonment of currently used habitat (Dooling and Popper 2007, Barber et al. 2010, Siemers and Schaub 2011). The level of effect depends on the extent and duration of from those activities over the current baseline, which is dominated by a busy and noisy highway. The predicted noise and visual disturbances during construction are considered to be only slightly greater than the current baseline of activity in the LAA, which is dominated by three high-volume highways; Highways 99, 17A, and 17 (**Section 4.10 Atmospheric Noise**). Sensory disturbance during Project construction will also be temporary, and intermittent over the five year construction period, with the greatest noise experienced in the first year when clearing, grubbing, and ground preparation is conducted.

The species that occur in and around the Project alignment are generally common, and are habituated to human activities that occur in such developed areas. The existing level of sensory disturbance on wildlife along the Project alignment is very high, and the species present are acclimated to noise and light disturbance associated with an active transportation corridor and agricultural production. A temporary increase in ambient noise levels due to construction activities is unlikely to alter the ability of species currently present to use the area permanently. Temporary abandonment around construction sites will occur (i.e., raptors and great blue heron within 100 m of construction sites), but re-establishment after construction is complete is anticipated. Beyond 100 m, given current human activity (noise and movement) the abandonment of habitat by wildlife is unlikely.

The potential for Project construction-related changes in water quality (and quantity) to affect wildlife is extensively addressed in relation to amphibian effects (**Section 4.5 At-Risk Amphibian Assessment**). The mitigation proposed for amphibians will also address potential Project-related effects for upland and riparian birds and mammals, and no additional effects, or mitigation is considered necessary to address terrestrial or semi-aquatic wildlife. As such, water quality effects on terrestrial and semi-aquatic wildlife will not be considered further.

Operation Phase

The additional light and noise sensory disturbance effects on wildlife over and above that from the existing Highway 99 in the LAA is considered to be negligible, and will not be considered further except in relation to bird impacts with the new bridge. Vehicle activity, noise, and lighting from highway operations have the potential to cause abandonment of otherwise useable wildlife

habitat. However, existing operation of Highway 99 has created a baseline level of effects such that Project-related increases in traffic are not expected to result in substantial changes in disturbance to wildlife.

Noise levels in the LAA are dominated by traffic noise and are currently high (**Section 4.10 Atmospheric Noise**). The species that use the LAA have adapted to such conditions. Songbirds, a wildlife group that relies on auditory signals for communications, are depressed in distribution and abundance in the LAA over what might be expected, likely due to the current noise levels. Point count observations in the LAA found limited numbers of only common species (**Table 4.8-8**). Peak noise levels up to 90 dB were recorded during surveys, which is considered high in relation to the needs of bird communication (threshold value of 45 dB; Reijnen and Foppen 2006, Dooling and Popper 2007, Barber et al. 2010). For highways that introduce new noise, there is potential for effects, however, in an environment with existing noise levels between 51.5 and 75.0 dBA, and with maximum predicted increases of 2.2 dBA (**Section 4.10 Atmospheric Noise**), effects are considered negligible. Future increases in road traffic will increase noise with or without the Project. The difference between the maximum increases with the Project (2.2 dBA) and without the Project (1.8 dBA) is small, and is further evidence that potential Project-related changes in sensory disturbance to terrestrial wildlife are negligible.

Sensory disturbance to terrestrial and semi-aquatic wildlife as a result of Project-related changes to the light environment is considered negligible. Light from vehicles is considered a small incremental increase because the current traffic volumes are high, and after completion of the Project the increase will be unnoticeable as it relates to sensory disturbances. Interchange lighting will be similar to that of the existing highway in the LAA (**Section 1.1 Description of Proposed Project**), and no changes to wildlife effects are expected. New Project lighting design will include standard practices (e.g., shielding interchange and bridge pier lighting to reduce light trespass or glare onto adjacent areas) that will minimize sensory disturbance to terrestrial wildlife, and avoid changes at the currently lit areas of Highway 99 (B.C. MOTI 2013). Accordingly potential sensory disturbance from changes to the ambient light environment will not be considered further.

Potential attraction of avian wildlife to the new bridge that could lead to mortality as a result of Project-related changes in the light environment is addressed below under Wildlife Mortality.

Wildlife Mortality

Construction Phase

Wildlife present in the Project alignment are mostly highly motile, and therefore considered less at risk from mortality during site preparation activities (e.g., vegetation clearing and grubbing, Deas Slough Bridge decommissioning).

Upland and riparian bird populations in the affected footprint are not unique and many similar habitats for foraging and nesting occur nearby. These species will vacate the affected areas during construction, and will likely re-occupy the new ditch areas once construction is complete and ditch vegetation has re-established. During nesting, riparian and upland birds have high fidelity to their nest sites, and are less mobile (Demarchi and Bentley 2005). As such, clearing and grubbing, and bridge removal at Deas Slough have the potential to affect bird nests and eggs. During 2015 field surveys conducted for the Project, barn swallow nests were detected on the Deas Slough Bridge. Implementation of mitigation measures (e.g., bridge removal outside of the breeding season, placement of exclusion netting) during bridge removal will prevent mortality of nesting swallows, if present. Also, mitigation to prevent construction-related effects on nesting raptors will minimize effects on a red tailed hawk nest at Green Slough, and others that occur within or close to prescribed protection buffers (Demarchi and Bentley 2005).

Small mammal populations within areas that overlap with Project components are not considered to be unique, and no at-risk species were found to be present. Because Project construction associated with highway widening and interchange upgrades in and around upland ditches will be undertaken in accordance with the Ministry's *Standard Specifications for Highway Construction* (B.C. MOTI 2012), the impacts on small mammal populations are considered to be negligible. In this respect the mitigation for reducing potential effects on amphibians (**Section 4.5 At-Risk Amphibians Assessment**) is considered to also reduce the effects on mammals. Potential construction-related mortality effects on mammals will not be considered further.

Operation Phase

During operation of the Project, wildlife has the potential to be impacted by vehicle collisions, and by colliding with the bridge while in transit to other locations. Across Canada, approximately 35 birds per kilometre of road are killed during the breeding and fledging season through vehicle collisions; mostly these are perching songbirds and owls (Bishop and Brogan 2013).

For upland birds, changes to Highway 99 are not expected to markedly alter the level of effects over those currently seen. Traffic volumes are currently high, and after completion of the Project will continue to be high. Given the current traffic volumes, incremental future Project-related collision mortality increases are considered negligible over the current baseline. Collision mortality effects are not considered further, with the exception of the at-risk upland bird species addressed below.

Bats use sight and acoustic senses to find prey, and avoid collisions. Most species avoid lit areas, and in unlit areas their senses are sufficient to avoid collisions with stationary objects. Collision mortality effects are not expected to increase during the operational phase of the Project and are not considered further. The at-risk listed great blue heron commonly forages in ditches in the Project alignment. The current level of effects on this species is not fully known, but their behaviours in the Project alignment (i.e., walking or wading in ditches in pursuit of prey, rarely flying unless forced to do so by disturbances) suggest that effects are uncommon. Traffic-related effects are not listed as impacting this species (Vennesland 2004). Great blue heron collision effects are considered negligible currently, and in the future are likely to be similar given the modest difference between the increases in traffic volumes with and without the Project along the corridor. Collision-related mortality effects on great blue heron are not considered further.

Barn owl are known to be affected by road collision mortality (Ramsden 2003, Marti et al. 2005, Preston and Powers 2006, Boves and Belthoff 2012). These mortalities are a result of collisions during forced (no other habitat available) or voluntary use of highway verges where their primary prey, voles, is found in high densities (Taylor 1994, Hindmarch et al. 2012), or from crossing roads between suitable habitat. Relevant mitigation was included in the design for the nearby Highway 17 to minimize effects on barn owl (B.C. MOTI 2006).

For birds travelling along the Fraser River, replacement of the Tunnel with a bridge will result in a new obstruction, and potentially increased collision risk. Collision with such structures often occur in association with smaller, less-visible components (e.g., cables), and during periods of low light/visibility (e.g., dawn, dusk, night, fog). Injuries and mortalities from transmission wires and other obstructions are well documented, and tend to be focused in the following species groups: wading birds, waterfowl, gulls, shorebirds, cranes, terns, corvids and raptors (Savereno et al. 1996, Janss 2000, Manning Cooper 2004, EDM 2008).

Many of these groups are present at the proposed new bridge crossing location, and many are currently flying at elevations that could place them at some risk. Most (>71%) of the birds that are currently flying at elevations that place them at risk are from species groups that are known

to have combinations of characteristics such as awareness of structures, faster reactions and greater maneuverability such that they avoid collisions more than others. This includes species groups with good flying abilities and known use of such structures for roosting and nesting such as pigeons, swallows and cormorants. Collision effects to these groups are considered unlikely. For the others, behavioral observations at the Port Mann bridge reference site show that most birds avoid collisions by flying above or below structures (**Figure 4.8-3**), likely as part of planned avoidance. A similar outcome is expected to be shown by Fraser River birds in the LAA. Structure lighting required for safety, with controllable LED and shielding or directionality such that the bridge deck is lit, and flashing navigation safety lighting on the top of the towers will be included in the design of the new bridge. Appropriate mitigation measures to minimize the attraction of birds, including provision of minimum necessary lighting and flashing navigation safety lighting (Gaston et.al. 2012, Gehring et.al. 2009), will be considered in the design of the new bridge.

4.8.4 Mitigation Measures

Selection of mitigation measures was informed by standard industry and best management practices (BMP); mitigation measures and follow up programs undertaken for past developments by the Ministry of Transportation and Infrastructure; input from regulators, public and Aboriginal Groups; and evaluation of technical and economic feasibility of mitigation. Standard industry practices proposed to avoid or reduce adverse effects on terrestrial wildlife were based on a review of the following key sources:

- *2012 Standard Specifications for Highway Construction* (B.C. MOTI 2012).
- *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010).
- *Develop with Care 2014: Environmental Guidelines for Urban and Rural Land Development in British Columbia* (B.C. MOE 2014a).
- *Best Management Practices for Raptor Conservation during Urban and Rural Land Development in British Columbia* (Demarchi and Bentley 2005).
- *Best Management Practices Guidelines for Pacific Water Shrew in Urban and Rural Areas* (Craig et al. 2010).
- *Best Management Practices for Priority Species at Risk in the South Coast Region of British Columbia* (B.C. MOE 2009).
- *Riparian Restoration Guidelines* (B.C. MOE 2008).
- *Tree Replacement Criteria* (B.C. MELP 1996).
- *Recovery Plan for the Barn Owl (Tyto alba) in British Columbia* (B.C. MOE 2014b).
- *National Guide to Erosion and Sediment Control on Roadway Projects. Transportation Association of Canada* (TAC 2005).

A hierarchical approach based on the four types of mitigation as outlined below was used in identifying strategies to avoid or minimize potential Project-related effects. Avoidance mitigation is highly effective, and the mitigation gets less and less effective moving down the hierarchy.

- **Avoidance:** Measures to avoid potential effects on the VC have been/will be incorporated into project considerations such as site and route selection, project scheduling, project design, and construction and operation procedures and practices.
- **Minimization:** Where potential effects on the VC cannot be avoided through project considerations, standard mitigation measures, BMPs, and construction and operation environmental management plans (EMPs) will be implemented to minimize potential Project-related effects or reduce them to acceptable levels.
- **Restoration or Habitat Enhancement:** Where potential Project-related effects cannot be avoided or minimized through standard mitigation measures, best practices, or implementation of EMPs, affected components will be restored on-site to pre-Project conditions.
- **Compensation/offset:** Where on-site restoration is not feasible, appropriate means to counteract, or make up for potential Project-related effects on the VC will be identified.

4.8.4.1 Avoidance

Highway 99 improvements are proposed to occur within the existing Highway 99 right of way, in large part avoiding effects on previously undeveloped areas. Ongoing refinement of the Project alignment has resulted in approximately 50 % reduction in effects on municipal ESA, including the high-value hub habitat identified by the City of Richmond. Utilizing some of the sub-optimal barn owl foraging habitat in the existing Highway 99 right-of-way to accommodate Project components will avoid to some degree, the collision effects on barn owl that are currently attracted to these areas.

4.8.4.2 Minimization

Project Design

The Project design will incorporate standard practices for lighting systems for highways and roadways under the jurisdiction of the Ministry (B.C. MOTI 2013). The lighting design will address safety requirements while including standard practices (e.g., shielding interchange and bridge lighting to reduce light trespass or glare onto adjacent areas) to minimize sensory disturbance to terrestrial wildlife from changes in the ambient light environment the bridge, and the currently lit areas of Highway 99 (B.C. MOTI 2013).

Where avoidance is not possible, the effects on terrestrial wildlife habitat from clearing and grubbing of vegetation will generally be minimized and restricted to the minimum necessary.

Highway width will be in accordance with applicable geometric standards, and the right-of-way will be minimally vegetated. Minimally-vegetated road shoulders and adjacent slopes limit the extent of infrequently-disturbed grass habitat that is suitable for barn owl prey resources (i.e., small mammals including Townsend's vole), reducing the attractiveness of the Project alignment for barn owl hunting and therefore lowering the collision risk. A similar approach is being used on Highway 17.

Best Management Practices and Environmental Management

Environmental protection measures that will be implemented during Project construction and operation to avoid or minimize potential effects on vegetation will be outlined in a Construction Environmental Management Plan (CEMP), and subsequently in an Operation Environmental Management Plan (OEMP), see **Section 12.0 Management Plans**. The CEMP will include vegetation and wildlife management, and invasive species management approaches. The plans will describe standard best practices and Project-specific mitigation measures to prevent or minimize potential adverse effects on wildlife that might otherwise result from the Project during construction. Key elements of these plans are discussed below. Many of these measures are required by legislation, government directive or are industry standards (see **Section 4.8.4**). Through their application on many Lower Mainland projects they are considered to be highly effective in managing effects.

Terrestrial Vegetation and Wildlife Management

Terrestrial vegetation and terrestrial and semi-aquatic wildlife management will include measures, such as avoidance (spatial and temporal), and minimization strategies to mitigate potential adverse effects to terrestrial wildlife and semi-aquatic wildlife, including pre-construction requirements such as nest survey protocols, otter latrine and den surveys, timing window restrictions, buffer zones, and wildlife salvage procedures that may be required. Offsetting measures, if warranted, will also be described. Most of these measures are required by legislation, government directive or are industry standards and are therefore are considered to be highly effective in managing effects.

Scheduling Activities to Avoid or Minimize Effects

To the extent feasible, Project construction activities will be planned to coincide with least-risk timing windows for wildlife; a technique recognised to be highly effective in managing effects. Management approaches will define timing windows during which there is potential for adverse

effects on terrestrial and semi-aquatic wildlife, and recommend low risk scheduling for construction and operation activities. In the event that least risk windows cannot be adhered to, mitigation to minimize the effects will be described. The CEMP will be developed in parallel with finalizing Project design and construction methods.

For example, site clearing and grubbing is expected to be conducted outside of the bird breeding season, approximately March 15 or earlier (February 1) for raptors, until July 31, in accordance with *Wildlife Act* and MBCA requirements. Avoiding bird breeding season is preferred to surveying to establish nest absence prior to within-season site clearing.

If the removal of Deas Slough Bridge cannot be scheduled to avoid the active nesting season for swallows (i.e., April 1 to July 31), then the underside of the bridge structure will be netted-in prior to the breeding season and prior to bridge decommissioning to exclude nesting swallows.

Pre-Construction Surveys

Where clearing and grubbing must proceed during the bird breeding season, nest surveys will be conducted prior to the start of such works to confirm the presence/not detected status of breeding birds, and location of nesting sites. Construction can proceed if identified nests are unoccupied and are not of a species protected year-round by the *Wildlife Act*.

Details of the timing and extent of pre-clearing surveys will be outlined in the CEMP for the Project, and will address the likely dates of clearing, known nest sites, early-breeding raptors and later-breeding songbirds, and federal and provincial guidance (Demarchi and Bentley 2005). Follow-up actions in the event of occupied nests being identified include monitoring responses to construction activity, gradual starts to habituate birds to activity, or temporary cessation of activity until the nest is inactive. These approaches follow industry best management practices and, depending on the species / species group are moderately to highly effective in managing effects.

Wildlife Salvage and Translocation

Prior to clearing and grubbing, wildlife salvage may be undertaken if there are locations of known small mammal occurrences. Salvages will be conducted in an enclosed area to prevent trapped species from returning to the area once removed. Salvage trapping and removal will be undertaken in accordance with *Wildlife Act* permits. These approaches follow industry best management practices and, depending on the species / species group are moderately to highly effective in managing effects.

Flagging and Management of Sensitive Wildlife Sites

Sites important to wildlife species, including raptor nest trees and river otter maternity den locations, will be flagged in the field and marked on Project plans to provide a visual barrier to contractors indicating that such areas need special provisions (as specified in Environmental Protection Plans for the site) during construction. This is a highly effective mitigation technique.

Around active raptor nests and occupied otter maternity dens, buffers will be delineated, and activities will be restricted outside these buffers if Project construction is to proceed during the raptor or otter breeding season (i.e., the period when female otters are using maternity dens for rearing). The size of buffers will be determined in consultation with MFLNRO, generally taking into account the time of year, species, type of construction activity, and proximity of construction to the nest or den site.

Wetland areas (e.g., Green Slough) will also be demarcated (see **Section 4.5 At-Risk Amphibian Assessment** and **Section 4.7 Vegetation Assessment**).

4.8.4.3 Habitat Enhancement

Increased traffic volume (see **Section 5.1 Traffic**) is anticipated to result in a very small increased collision risk for barn owl within the Project alignment. Experience in addressing such risk, during the development of Highway 17, has demonstrated that hedgerows and fences erected to force over-flights by barn owl at elevations greater than the heights of vehicles, have been effective in reducing such mortality risk. The effectiveness of such mitigation is supported by academic studies (Massemin and Zorn 1998, Pons 2000). Hedgerows and fences will be erected in high-risk areas to reduce the increased collision risk for barn owl within the Project alignment. Full effectiveness requires that hedgerows are approximately 2-3 m, which may require up to ten years to attain. Experience on Highway 17 shows that planting in advance of construction reduces the time to achieve effective height.

4.8.4.4 Habitat Offsetting

Decommissioning and removal of the Deas Slough Bridge will remove a structure currently used for nesting by barn swallows. Suitable replacement structures for nesting will be provided in advance of Deas Slough bridge removal, with the construction of the new bridge, and within the access route for maintenance of the new piers. Consultation with biologists during the design of the new bridge will ensure that suitable bridge features close to water (Green Slough and Deas Slough) are included and will offset effects from the decommissioning of the Deas Slough Bridge. This mitigation is considered effective, as evidenced by high-use of Highway 17 structures by barn swallows (>15 nests on the new Burlington Northern Santa Fe Railway overpass for Highway 17 in June 2015).

Construction activities associated with bridge pier footings at the north Tunnel portal and along Green Slough will not directly affect the two documented extant river otter latrine sites within the Project alignment. Indirect effects during the construction period (temporary abandonment of the sites) is expected, with re-use of these sites or a shift to other suitable nearby areas (of which there is evidence of many) expected. Follow-up monitoring will be conducted to confirm this prediction.

4.8.5 Residual Effects and their Significance

4.8.5.1 Characterization of Residual Effects

Residual effects are those adverse effects that remain following implementation of mitigation measures. Potential residual effects on terrestrial wildlife are characterized by quantitatively or qualitatively assessing the direction, magnitude, extent, duration, frequency, and reversibility of the effects. Definitions for ratings applied to residual effects criteria, developed with specific reference to terrestrial wildlife have been developed (**Table 4.8-12**). The potential residual effects to terrestrial wildlife considered further in this assessment are:

- Habitat loss for barn swallows (upland birds) during Project construction only
- Direct mortality to barn owl (upland birds) during Project operation only

Table 4.8-12 Criteria used to characterize residual effects on terrestrial wildlife

| Characteristic and Description | | Rank and Description of Associated Effect | | | |
|--------------------------------|--|---|---|--|---|
| Direction | Whether an effect is positive, neutral, or negative (adverse) | Adverse | Positive | Neutral | |
| | | Negative effect as a result of the Project | Beneficial effect as a result of the Project | Neutral effect as a result of the Project | |
| Magnitude | Intensity of the effect relative to natural or baseline conditions | Negligible Magnitude | Low Magnitude | Moderate Magnitude | High Magnitude |
| | | No measurable change in avian or small mammal relative abundance (mortality), habitat quantity or quality (i.e., area of habitat shifting from high- to low-quality | A measurable change relative to baseline conditions, but not affecting wildlife population viability (presence maintained, <10% reduction in high or medium quality habitat in LAA) | A measurable change relative to baseline conditions outside the range of natural variability, but not posing a risk to population viability (presence maintained, 10-15% reduction in high or medium habitat in LAA) | A measurable reduction in relative abundance outside the range of natural variability that may affect long-term population viability (extirpation, >15% reduction in high or medium habitat in LAA) |
| Extent | Geographic extent/distribution of the effect | Specific Extent | Local Extent | Regional Extent | |
| | | Effect is restricted to the immediate Project footprint | Effect is restricted to the LAA | Effect is restricted to the RAA | |
| Duration | Likely duration of the potential effect e.g., how long the stressor impacts the VC | Transient-term | Short-term | Medium-term | Long-term |
| | | Effect occurs once during construction or operation | Effect occurs throughout construction or operation | Effect to the indicator continues to the end of the operation phase | Effect to the indicator continues beyond the life of the Project |

| Characteristic and Description | | Rank and Description of Associated Effect | | | |
|--------------------------------|---|--|--|---|--|
| Frequency | Nature of the occurrence of the effect; e.g., how often the stressor impacts the VC | Rare | Uncommon | Frequent | Continuous |
| | | Effect occurs once during construction or operation | Effect occurs intermittently (once per month) during construction or operation | Effect occurs once per week during construction or operation | Effect occurs daily during construction or operation |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after removal (or after a period of time after removal) | Reversible | Irreversible | Change | |
| | | Baseline conditions will be naturally restored after disturbance has ceased, or offsetting can restore | Baseline conditions will not be naturally restored after disturbance has ceased, and cannot be restored artificially | Effect may fluctuate between positive and adverse for the duration of the Project | |

Residual Effect #1: Barn Swallow Habitat Loss

The removal of the Deas Slough Bridge will result in the loss of barn swallow nesting habitat, thus the effect is considered adverse in direction and specific in extent. In 2015, the Deas Slough Bridge hosted 13 barn swallow nests, of which, approximately a third (or five nests) appeared to be actively used. Between 9 and 16 barn swallows were frequently observed foraging around the Deas Slough Bridge in summer 2015. Barn swallows are closely associated with humans and human structures, and may be using other nearby locations such as boat houses at Captain's Cove Marina, barns on River Road, and under eaves on the River House development, where nesting was also observed. Mud, an essential habitat requirement for nest building, is abundantly available in the LAA, especially Deas and Green sloughs.

Habitat loss associated with the removal of Deas Slough Bridge is considered of moderate magnitude, as the bridge is one of the few barn swallow nesting locations available within the LAA. Because it is a developed corridor, the LAA provides very few opportunities for barn swallow nesting; however, a large number of other suitable nesting habitat, particularly barns, boathouses, and other buildings, are available just outside the LAA, which is expected to minimize the magnitude of habitat loss effects associated with decommissioning of the Deas Slough Bridge.

The loss of barn swallow nesting habitat is of temporary duration because the new bridge will be constructed and new nesting habitat will become available before the Deas Slough Bridge is removed. The new bridge, which will be built in the same location as the existing Deas Slough Bridge, may provide nesting opportunities on features appropriate for barn swallow nest establishment (e.g., vertical walls with ledges close to water and a source of mud). It is anticipated that Project-related construction will provide more area for potential nest establishment than is currently available. Therefore, the effect is considered reversible and may be avoided altogether if the new structures are used by barn swallows before the Deas Slough Bridge is removed. In the event that the new bridge does not provide such habitat, because it will be a greater height above the river than the Deas Slough Bridge, artificial structures can be constructed to supply the necessary habitat. A summary of the criteria ratings for possible barn swallow residual effects has been provided (**Table 4.8-13**).

Table 4.8-13 Criteria ratings for barn swallow habitat loss residual effect

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|--|
| Direction | Adverse | Removal of nesting habitat is a negative effect. |
| Magnitude | Moderate | Nesting habitat loss occurs naturally; restoration onsite, or other nesting locations nearby will maintain the population. |
| Extent | Specific | Effect to one small area of the Project alignment. |
| Duration | Transient-term | Habitat loss will likely be transient-term – replacement structures (e.g., new bridge) will be available in advance of the loss due to Deas Slough Bridge decommissioning. |
| Frequency | Rare | The effect occurs only once. |
| Reversibility | Reversible | Effects are reversible through establishment of replacement nesting habitat (the new bridge or an artificial structure). |

Residual Effect #2: Barn Owl Mortality

Highway 99 will continue to see traffic growth (**Section 5.1 Traffic**). While this may be considered to lead to additional barn owl mortality, such increases would be very small, and difficult to estimate given the existing levels of mortality. Vehicle collisions with barn owls on Highway 99 in the Highway 17 to 91 portion of the Project alignment are currently estimated at around twenty barn owls per year (actual numbers observed are lower). With or without the Project, higher traffic volumes are expected in the future. Current traffic volumes are already high and the increase with the Project (as compared to without the Project) is a negligible additional risk because the traffic volume increases are anticipated to occur during daytime hours, when barn owls are largely inactive (Taylor 1994). The incremental increase in collision risk for barn owl is not considered a risk to population survival for a number of reasons. The proposed mitigation (flight-height diverters) is considered to be effective in addressing the incremental mortality risk; it is being used successfully on the nearby Highway 17. This mitigation may also reduce the existing impact (**Section 4.8.4 Mitigation Measures**). Barn owl populations have relatively high breeding rates, and in the absence of high effects, can maintain population numbers.

Barn owl numbers appear to be relatively stable in the study area (Hemmera 2014), however mortality on existing highways and the loss of nesting structures as barns are demolished or replaced are drivers that place Lower Mainland barn owl populations at some risk. Barn owls are close to the northern edge of their range in southwest Delta, and the location is one of the highest concentrations for the species in Canada.

The magnitude of the residual effect is considered negligible, but of long-term duration, as it is expected to occur for the life of the Project. The residual effect is characterized as reversible because mitigation may serve to reduce the existing effects. Implementation of mitigation measures (e.g., flight-height diverters to minimize collision risk, habitat management in the right-of-way to minimize attractiveness of roadside verges for foraging owls) is expected to reduce the level of effect. A summary of the ratings for barn owl mortality has been provided in **Table 4.8-14**.

Table 4.8-14 Criteria ratings for barn owl mortality residual effect

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|---|
| Direction | Adverse | Potential additional mortality is a negative effect |
| Magnitude | Negligible | Potential additional mortality effects are difficult to quantify; but in an at-risk population, one incidence of mortality per annum could be considered a measureable change. In barn owl populations such as in the LAA which have relatively high breeding success, such mortality is not a risk to populations. |
| Extent | Specific | Effect limited to one portion of the Project alignment and LAA |
| Duration | Long-term | Additional mortality effects are for the life of the Project |
| Frequency | Uncommon | Mortality effects are likely intermittent (but difficult to quantify). |
| Reversibility | Reversible | While mortality effects are not reversible, populations can recover, or be maintained, under some mortality pressure. Mitigation may reduce current mortality observed in the LAA. |

4.8.5.2 Likelihood

The likelihood of a residual effect occurring is influenced by existing conditions, Project activities, potential effects, and the implementation of mitigation measures. Information on these factors is used to determine the likelihood of there being an adverse residual effect. The likelihood of a residual effect on terrestrial wildlife occurring is characterized as:

- Low – Chance of the residual effect to occur is less than 25%.
- Moderate – Chance of the residual effect to occur is between 25% and 75%.
- High – Chance of the residual effect to occur is greater than 75%.

Table 4.8-15 summarizes the likelihood ratings of a residual effect on terrestrial wildlife occurring and provides the rationale for the rating.

Table 4.8-15 Likelihood rating of a residual effect on terrestrial wildlife

| Residual Effect | Likelihood Rating | Rationale for Rating |
|---|-------------------|---|
| Barn swallow (upland bird) habitat loss | Low | Mitigation is considered effective and proven |
| Barn owl (upland bird) mortality | Low | Mitigation is considered effective and proven, and will address the small incremental change due to the Project |

4.8.5.3 Proponent’s Determination of Significance

Significance Definition

Species and species groups comprising upland bird, riverine bird, and small mammal (including river otter) subcomponents do not have legislated or regulated thresholds to define significance. Instead, VC-specific factors were used to define significance (B.C. EAO 2013). For each effect, habitat loss, habitat alteration, and mortality (**Table 4.8-2**) were used to measure the effects characteristics and establish significance. A significant effect is considered to be one that results in population(s) at individual sites not being self-sustaining after Project implementation.

Specifically:

- An effect is considered significant if it is characterized as adverse, of high magnitude, and not reversible, in addition to any of the following: frequent/continuous, medium/long-term, and regional extent.
- An effect is considered not significant if characterization does not meet the above criteria.

Significance Determination

This section presents the determination of significance of residual effects of the Project on terrestrial wildlife in terms of barn swallow habitat loss and barn owl mortality, considering the likelihood of a significant adverse effect (**Table 4.8-16**).

Barn Swallow Habitat Loss

The potential habitat loss effect on barn swallow is adverse. The magnitude of the effect is moderate, because the Deas Slough Bridge represents one of the few areas within the LAA that suitable for barn swallow breeding. However, the effect is reversible as the new bridge and approaches will provide alternative habitat. The new structures are anticipated to provide more area suitable for establishment of nests than is lost with the removal of the Deas Slough Bridge, and that habitat will be available for establishment of nests before the loss occurs. In this context, this residual effect is considered not significant.

Barn Owl Mortality

The incremental change in barn owl mortality due to vehicle collisions as a result of the Project is not expected to affect barn owl populations. Barn owls have relatively high breeding success and implementation of mitigation measures, specifically the combination of habitat reduction and management of the remaining habitat to reduce barn owl prey in the right-of-way and construction of flight-height diverters, is expected to minimize some of the current and any incremental future effects. Although the effect is characterized as adverse, it is expected to be of negligible magnitude, uncommon frequency, and specific in extent. With the successful implementation of mitigation measures, effects may be reversible. This residual effect is considered not significant.

Table 4.8-16 Determination of significance of residual effects for terrestrial wildlife

| Residual Effect | Significance (significant/not significant) | Likelihood (low/moderate/high) |
|--|---|---------------------------------------|
| Barn swallow (upland birds) habitat loss | Not significant | Low |
| Barn owl (upland birds) mortality | Not significant | Low |

On the basis that implementation of mitigation will minimize the level of residual effects (i.e., habitat is expected to be available for establishment of barn swallow nests before removal of the Deas Slough Bridge, flight-height diverters will be constructed to minimize barn owl mortality as a result of vehicle collision, and sub-optimal habitat close to Highway 99 that currently attracts barn owl will be reduced) the residual effects of the Project on terrestrial wildlife are considered to be not significant. The populations of these species are expected to be self-sustaining in the LAA and in the portions of the Project alignment where they currently occur after Project implementation; as such the likelihood of a significant effect is low and the residual effects are considered not significant.

4.8.5.4 Confidence and Risk

The prediction of confidence was based on expert judgment and includes characteristics that determine the level of uncertainty associated with both the significance and likelihood determinations. The level of confidence is based on scientific information, professional judgment of the discipline expert, effectiveness of mitigation, and assumptions made. The level of confidence in the effects predictions for barn owl and barn swallow, associated with both the significance determination (not significant) and the likelihood (low), is moderate to high, because:

- There are good data to understand the potential effects. The quality and reliability of the data that supported the assessment was rated moderate (**Section 4.8.2.4**). Standard sampling methods, or reliable methods published in government-approved or peer-reviewed documents were used. As well, the availability of data for the area surrounding the LAA (including in the RAA) is reasonable, in large part from the Ministry's studies on the nearby Highway 17/SFPR.
- Efficacy of mitigation based on past and ongoing experience with the management of these species. The experience in identifying and managing effects on barn owl from the nearby SFPR gives high confidence in the likelihood of effects for that species, and the means by which they should be managed. Recent attention to the management of barn swallow in the Lower Mainland gives better confidence on the predicted level of effects and the mitigation needs for the species.

Given the moderate to high confidence level in the effects prediction, the anticipated non-significant residual effects, and the proposed monitoring and follow-up programs, risk is determined to be low and risk analysis is not required (see **Section 3.9 Confidence and Risk**).

4.8.6 Cumulative Effects and their Significance

Residual effects on barn swallow and barn owl as a result of the project were considered in combination with the known or projected residual effects on these species from past present or reasonably foreseeable projects (**Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**). The purpose is to determine the potential for interaction of residual effects in space and time, and if there is an interaction the significance of those combined effects (i.e., cumulative effects) and necessary mitigation.

For barn swallow the potential for other projects (**Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**) to result in residual effects to structures on which their nests are located is considered unlikely. Two of the projects identified the presence of barn swallow (i.e., Vancouver Airport Fuel Delivery, and Roberts Bank Terminal 2). There were no residual effects on this species, or the VC in which barn swallow is a component, identified for both projects. Both projects are solely or mostly located outside of the RAA (information obtained from the EAO ePIC document repository database and James Rourke, R.P.Bio. pers. comm.). Accordingly these projects are not considered further in this cumulative effects assessment because there is no interaction with the residual effects of the project under consideration. Other of the projects reviewed did not mention barn swallow as a VC, or as a component of a VC (i.e., Tilbury LNG Expansion, Fraser Surrey Docks Direct Coal Transfer, Westpac Tilbury Marine, Lehigh South Richmond Terminal Project, Kinder Morgan Trans Mountain Pipeline Expansion, and BC Hydro Massey Circuit Relocation (information obtained from EAO ePIC, Port of Vancouver and National Energy Board document repository

databases). These projects are not considered further in this cumulative effects assessment as there are no stated residual effects on the species under consideration, and therefore no interaction. For the remainder of the projects under consideration the proponents did not publish information describing their effects on barn swallow. To address these unknowns a review of the nature and extent of their projects with respect to barn swallow biology and nesting was conducted. Based on that review these remaining projects under consideration are not considered to have residual effects on barn swallow and therefore to not interact because they (i) lack the presence of structures suitable for breeding in their project areas (i.e., Fraser River Dredging and Port of Vancouver Habitat Enhancement), or (ii) the projects are too early in their design phases to adequately understand the potential for residual effects (i.e., Pattullo Bridge Replacement and Ladner Harbour Revitalisation). The Pattullo Bridge may not be removed as part of the works, and hence there may be no reduction in any available nesting habitat for barn swallow. These projects are also outside of the RAA.

As no interacting residual effects on barn swallow were determined for the projects under review (**Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**) this assessment finds no cumulative effects.

For barn owl the potential for other projects (**Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**) to result in residual effects from collisions is considered minimal. Two of the projects identified the presence of barn owl (i.e., Vancouver Airport Fuel Delivery, and Roberts Bank Terminal 2). There were no residual effects on this species, or the VC in which barn owl is a component, identified for both projects (information obtained from the EAO ePIC document repository database and James Rourke, R.P.Bio. pers. comm.). Accordingly these projects are not considered further in this cumulative effects assessment because there is no interaction with the residual effects of the project under consideration. Most of the other projects reviewed did not mention barn owl as a VC, or as a component of a VC (i.e., Tilbury LNG Expansion, Fraser Surrey Docks Direct Coal Transfer, Westpac Tilbury Marine, Lehigh South Richmond Terminal Project, Kinder Morgan Trans Mountain Pipeline Expansion, and BC Hydro Massey Circuit Relocation (information obtained from EAO ePIC, Port of Vancouver and National Energy Board document repository databases). These projects will not be considered further in this cumulative effects assessment as there are no stated residual effects on the species under consideration, and therefore no interaction. For the remainder of the projects the proponents did not publish information describing their effects on barn owl. To address these unknowns a review of the nature and extent of their projects, with respect to barn owl biology and collision effect potential, was conducted. Based on that review, these remaining projects are not considered to have

residual effects on barn owl and therefore to not interact because they do not include collision effects (i.e., Fraser River Dredging, Port of Vancouver Habitat Enhancement, and Ladner Harbour Revitalisation). The Pattullo Bridge Replacement involves vehicles that could collide with barn owl, and therefore may have an interaction. However, there are no known interactions with barn owl on the Pattullo Bridge, and the location and type of the replacement structure is unknown. There are three location options being considered, and one option includes a tunnel that has no potential for interaction with barn owl. The uncertainties with this project are too great for it to be considered further. An existing project that interacts with barn owl, the South Fraser Perimeter Road (SFPR, Highway 17) was recently constructed and opened. It crosses the Project Alignment just west of Burns Bog. Barn owl was identified as a valued ecosystem component during the environmental assessment review of the SFPR, and an adaptive management plan to design mitigation and monitor the efficacy of that mitigation was developed prior to approval. During and since construction, monitoring of barn owl populations along the SFPR and of effects on barn owl from the SFPR has been conducted. That monitoring indicates populations of barn owl have been maintained and that collision effects on barn owl, for example areas of higher-than-expected mortality, are being addressed through additional mitigation. The ongoing barn owl mitigation monitoring program on the SFPR project is effectively addressing the residual effects of the SFPR on barn owl. There is an interaction between the SFPR and the Project, but the active management of those effects currently being conducted on SFPR, and proposed for the Project (**Section 14.2 Summary of Mitigation Measures**) are considered to be an effective means of avoiding cumulative effects on barn owl in south west Delta.

4.8.7 Follow-up Strategy

Monitoring will be conducted during and after Project construction to ensure mitigation measures identified in **Section 4.8.4** are implemented and expected outcomes in terms of avoiding or minimizing effects on terrestrial wildlife, specifically barn swallow and barn owl, are achieved. Post-construction monitoring will focus on monitoring of barn swallow nest establishment, establishment of flight-height barriers / diverters (e.g., hedgerows) as barn owl mitigation) and the removal of barn owl foraging areas close to the highway. Post-construction monitoring will be conducted to confirm continued use of the two latrine sites within the LAA by river otter.

APPENDIX A

Overview of Potential Project Interactions with Terrestrial Wildlife

Table 1 Overview of Potential Project Interactions with Terrestrial Wildlife

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|--|------------------------|--|--|
| Pre-Construction / Site Preparation | | | |
| Pre-construction / site preparation | No Interaction | <ul style="list-style-type: none"> • Surveying • Acquiring land for the Project | <p>Nature of interaction: No interaction anticipated</p> <p>Comment: Activities are not anticipated to cause changes in habitat quality, or result in habitat loss or impact terrestrial wildlife</p> |
| | No Effect | <ul style="list-style-type: none"> • Preloading for embankment and highway construction • Conducting additional site investigations (i.e., a geotechnical drilling program) | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Installing temporary drainage structures and diversions • Installing temporary bridges and barging facilities • Installing temporary roads, laydown areas, and site offices • Relocating utilities • Clearing and grubbing of vegetation within the existing Highway 99 ROW • Restoration of Green Slough to its historic alignment | <p>Nature of interaction: Activities with potential to affect terrestrial wildlife</p> <p>Comment: Potential effects include:</p> <ul style="list-style-type: none"> • Habitat loss and direct mortality of terrestrial wildlife during vegetation clearing and grubbing, stripping, and soil excavation • Habitat alteration due to sensory disturbance from noise, dust, and presence and movement of construction crews and equipment |

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|--|------------------------|--|---|
| Construction | | | |
| New bridge including approaches and ramp connections | No Interaction | <ul style="list-style-type: none"> • Hoisting pre-assembled deck segments from barges in the river or land-based transport system | N/A |
| | No Effect | N/A | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Installing upland piers, including pile installation • Installing drainage structures/settling ponds • Ground improvements associated with new bridge piers • Installing piers adjacent to Deas Slough and Green Slough, including pile installation • Constructing approach spans (concrete deck slab on steel or concrete girder) • Constructing bridge towers and installing support cables using land-based equipment • Installing retaining walls | <p>Nature of interaction: Activities with potential to affect terrestrial wildlife</p> <p>Comment: Potential effects include:</p> <ul style="list-style-type: none"> • Habitat loss due to highway widening, permanent installation of upland piers, and restoration of Green Slough • Habitat alteration due to changes in surface water quality from dewatering and temporary diversion of upland ditches, and sensory disturbance related to noise, dust, presence and movement of construction crews and equipment • Accidental spills of deleterious substances (see Section 8.0 Accidents and Malfunctions) |

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|---|------------------------|---|---|
| Highway 99 improvements, including interchange upgrades | No Interaction | N/A | N/A |
| | No Effect | N/A | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Replacement of interchanges at Westminster Highway, Steveston Highway and Highway 17A • Replacement of over/underpasses at Cambie Road, Shell Road, Highway 91 Westbound Ramp, Blundell Road, Ladner Trunk Road and 112th Street • Highway widening from Bridgeport in Richmond to Highway 91 in Delta including construction of embankments, placing and compacting fill for road base, establishing improved drainage and paving | <p>Nature of interaction: Activities with potential to affect terrestrial wildlife</p> <p>Comment: Potential effects include:</p> <ul style="list-style-type: none"> • Habitat alteration due to changes in surface water quality from sedimentation, dewatering and temporary diversion of upland ditches, and sensory disturbance related to noise, dust presence and movement of construction crews and equipment • Direct mortality of small mammals during soil/gravel placing and compaction • Accidental spills of deleterious substances (see Section 8.0 Accidents and Malfunctions) |

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|---|------------------------|--|--|
| Tunnel decommissioning | No Interaction | <ul style="list-style-type: none"> • Removing electrical/mechanical/utilities equipment from the Tunnel • Removing of four Tunnel segments and associated scour protection • Backfilling of onshore portions of Tunnel approaches • Transporting Tunnel elements for offsite disposal, and operating support vessels for that activity | N/A |
| | No Effect | N/A | N/A |
| | Potential Effect | N/A | N/A |
| Decommissioning of Deas Slough Bridge | No Interaction | N/A | N/A |
| | No Effect | N/A | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Removal of Deas Slough Bridge including substructures | <p>Nature of interaction: Activities with potential to affect terrestrial wildlife</p> <p>Comment: Potential effects include</p> <ul style="list-style-type: none"> • Direct mortality of upland birds (e.g., destruction or failure of an active nest) • Habitat alteration due to sensory disturbance related to noise, presence and movement of construction crews and equipment • Accidental spills of deleterious substances (see Section 8.0 Accidents and Malfunctions) |

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|----------------------------------|------------------------|---|--|
| Operation and Maintenance | | | |
| Highway 99 and interchanges | No Interaction | N/A | N/A |
| | No Effect | N/A | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Operating reconfigured Highway 99 and interchanges • Highway 99 and interchange maintenance (drainage maintenance, winter maintenance, emergency maintenance, road cleaning, etc.) | <p>Nature of interaction: Activities with potential to affect terrestrial wildlife</p> <p>Comment: Potential effects include:</p> <ul style="list-style-type: none"> • Habitat alteration due to sensory disturbance related to incremental growth in traffic and associated ambient noise levels • Loss of small mammal and upland bird habitat due to periodic maintenance of roadside and upland ditch vegetation • Vehicle collisions with avian wildlife |

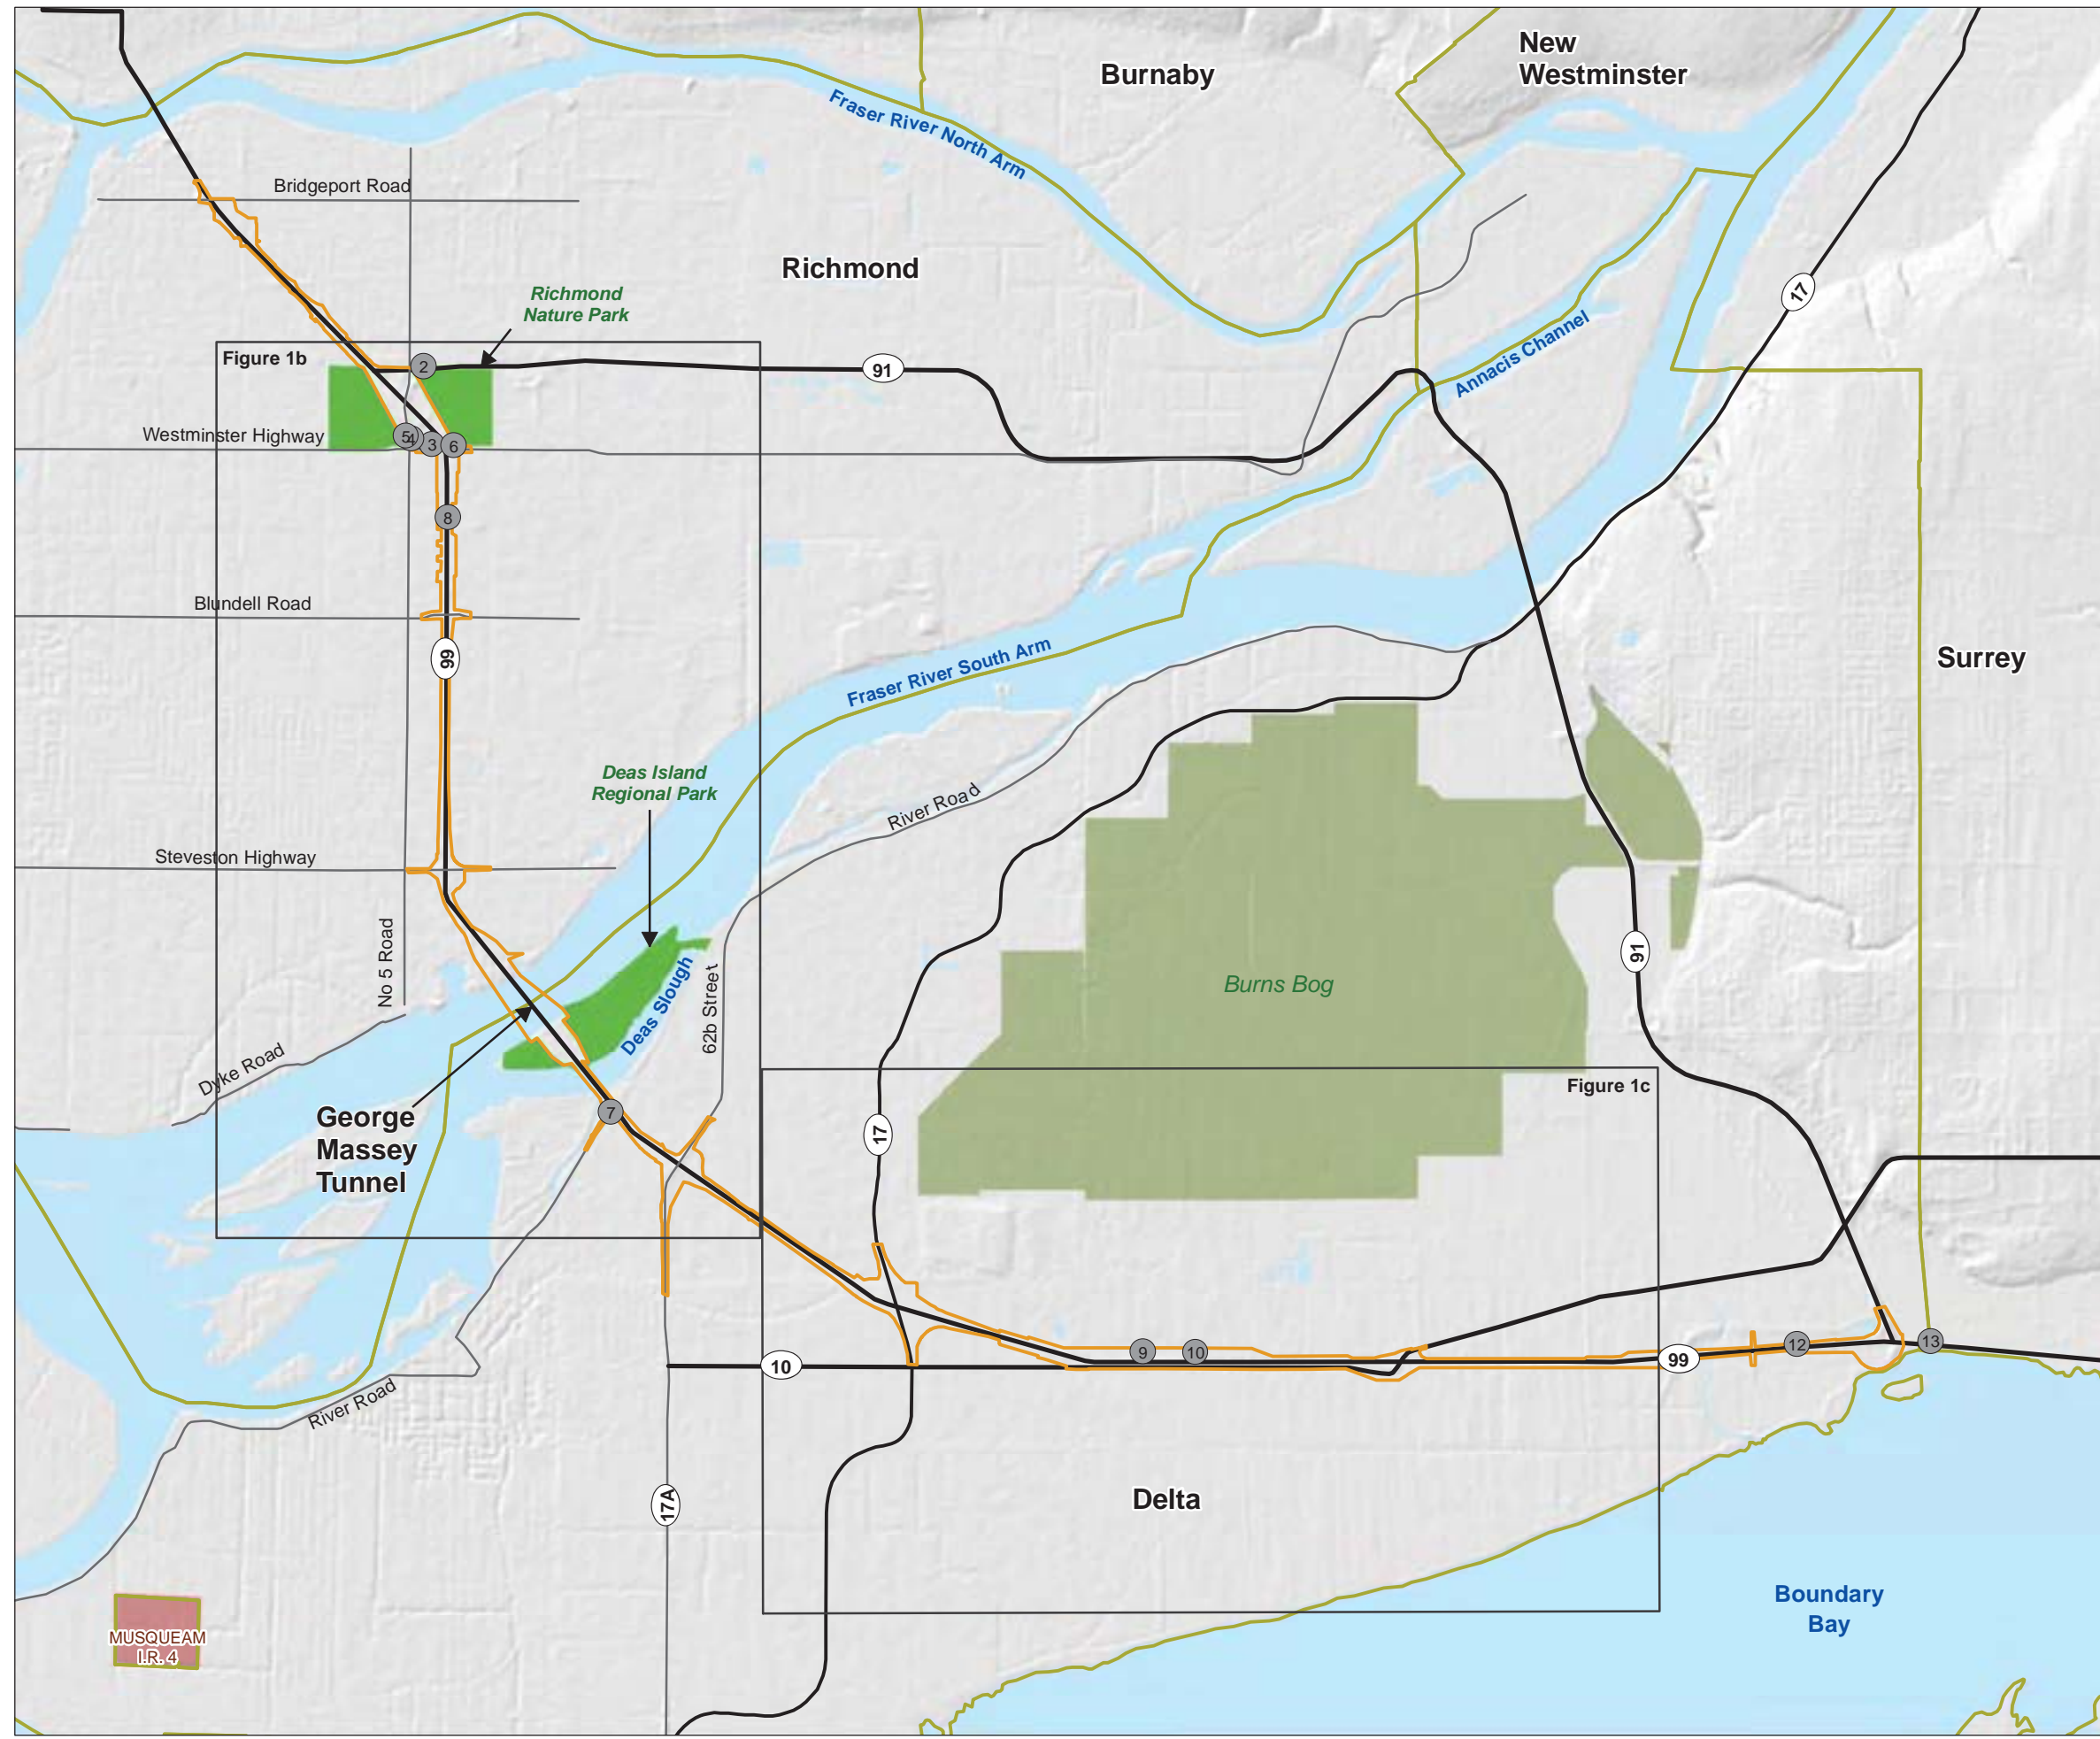

| Project Phase/ Component | Interaction Ranking | Project Works and Activities that Interact with the VC | Nature of Potential Interaction |
|-----------------------------|------------------------|---|--|
| New bridge | No Interaction | <ul style="list-style-type: none"> • Bridge maintenance (winter maintenance, emergency maintenance, structure maintenance, etc.) | <p>Nature of interaction: No interaction anticipated</p> <p>Comment: Activities are not anticipated to cause changes in habitat quality, or result in habitat loss or mortality of terrestrial wildlife</p> |
| | No Effect | N/A | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Operating the new bridge | <p>Nature of interaction: Activities with potential to affect terrestrial wildlife</p> <p>Comment: Potential effects include:</p> <ul style="list-style-type: none"> • Direct mortality of upland birds and riverine birds and bats as a result of collisions with the new bridge • Habitat alteration due to sensory disturbance related to incremental growth in traffic and associated ambient noise levels, and changes in the ambient light environment |

"N/A" indicates that no Project works and/or activities are applicable to the category

4.9 Air Quality Assessment Highlights:

- Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. Projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in.
- Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include:
 - A 35 % reduction in particulate matter emissions, as compared with a 14 % reduction without the Project.
 - A 47 % reduction in volatile organic compound (VOC) emissions, as compared with a 40 % reduction without the Project.
 - No exceedances of the current most stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.
- The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.
- Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.
- Construction-related effects on air quality will be minimized through implementation of recognized mitigation measures and best management practices that have proven to be effective on other transportation infrastructure projects in the Lower Mainland.
- No Project-related residual or cumulative effects on air quality are expected post construction.

4.9 Air Quality

This section describes the existing conditions related to air quality and anticipated changes resulting from Project components and activities. Air quality comprises one of the 'steps' along the pathway of effects of the Project, with human health identified as the ultimate receptor of Project-related effects. Air quality was therefore assessed as an intermediate component (IC) and predicted change in air quality was used to support the assessment of potential effects of the Project on human health, which was assessed as a valued component (VC) (**Section 7.1 Human Health Effects Assessment**).

A technical volume, **Air Quality Study**, containing further detail on existing conditions and methodology used in predicting Project-related effects is included in **Section 16.5**.

4.9.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on air quality in terms of Project setting, and defines the spatial, temporal, administrative and technical assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

4.9.1.1 Assessment Context

During pre-Application consultation on the Project with government agencies, Aboriginal Groups, and the general public, potential influence of the Project on local and regional air quality and consequent effects on human health was identified as an area of specific interest by Metro Vancouver, Aboriginal Groups, and health authorities. The Project involves improvements to Highway 99 to eliminate congestion, which will result in a reduction in vehicle emissions. Given the predicted decrease in congestion, air quality is expected to improve with the implementation of the Project. Predicting the anticipated nature and magnitude of such changes and the temporary influence of construction-related emissions on local air quality is important for assessing Project-related effects on human health, which has been defined as a VC. Air quality has therefore been selected as an IC in the context of assessment of potential effects of the Project on human health.

Additional information on the selection of VCs, and the link between air quality and human health is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**.

4.9.1.2 Methodology

The assessment of air quality follows the general methodology described in **Section 3.0 Assessment Methodology**.

The overall objective of the air quality assessment was to predict potential Project-related changes in air pollutant emissions and their net effect on ambient air quality in the Project alignment. In early 2014, the Ministry initiated field and desktop studies as well as modelling to support planning and environmental assessment of the Project. The studies (outlined in **Table 4.9-1**) were designed to build on existing information and address known data gaps. The objectives of the air quality studies were to:

- Characterize existing air quality as influenced by sources other than vehicle emissions.
- Estimate existing and future vehicle emissions.
- Use dispersion modelling to predict potential changes in local and regional air quality associated with the proposed Project.

Table 4.9-1 Studies to Support the Air Quality Assessment

| Study Name | Purpose of Study |
|------------------------------------|---|
| Existing air quality data analysis | Analyze ambient air quality monitoring data to determine the contribution of sources other than vehicle emissions to air quality in the vicinity of the Project and the lower Fraser Valley. |
| Emissions modelling | Estimate emissions from vehicle activity in the Project alignment in 2011 (existing conditions) and 2031 (future conditions with and without the Project), and compare with existing and forecasted emissions in the lower Fraser Valley. |
| Air quality dispersion modelling | Model meteorology and emissions data to estimate ambient concentrations for various averaging periods, and compare them to regulatory objectives. |

The studies were focused on the following regulated compounds:

- Criteria air contaminants (CACs)
 - Carbon monoxide (CO)
 - Nitrogen oxides (NO_x, NO, and NO₂)
 - Sulphur dioxide (SO₂)
 - Volatile organic compounds (VOCs)
 - Ammonia (NH₃)
 - Particulate matter (total PM, PM₁₀ and PM_{2.5})
- Road dust (total PM, PM₁₀ and PM_{2.5})
- Toxic air contaminants (TACs)
 - Aldehydes (acetaldehyde, acrolein, formaldehyde)
 - Polycyclic aromatic hydrocarbons (naphthalene, benzo(a)pyrene)
 - Benzene
 - 1,3-butadiene
 - Diesel Particulate Matter

The CALINE3 (CALINE) model was used in this study to estimate ambient concentrations resulting from vehicle exhaust on highways. CALINE is specifically designed for vehicle emissions from exhaust along roads. Although B.C. does not mandate or recommend the use of a particular model, CALINE is the model currently recommended by the US EPA for prediction of air quality impacts of roadway (line) emission sources. Because the CALINE model is US

EPA-approved, it has gone through rigorous evaluation to ensure that the model is providing appropriate results. Due to CALINE's conservatism, its predicted concentrations tend to be higher than observed ambient air quality, but the model will provide a worst-case estimate of a Project's effects on local air quality.

Vehicle emission factors were determined using the U.S. EPA MOVES2012b modelling simulator (U.S. EPA 2012). At the core of the methodology is the emission equation:

Emission (g) = activity data (VkmT) x emission factor (g/VkmT), where VkmT is the number of vehicle kilometres travelled.

Emission calculations for vehicles are complex because of the many methods needed to determine reliable emission factors and activity data. Emission factors can vary significantly depending on:

- Vehicle type (e.g., light duty vs. heavy duty, gasoline vs. diesel)
- Mileage accumulation (age of vehicle)
- Speed (e.g., 20 km/h vs. 100 km/h)
- Control technology (e.g., catalytic converters)
- Other emission-reduction measures

The MOVES model generates emissions factors for highway motor vehicles and motorcycles fuelled by gasoline, diesel, and compressed natural gas (CNG). It also accounts for the effects on emissions caused by changes in vehicle emission standards; changes in vehicle populations and activity; and variation in local conditions such as temperature, humidity, atmospheric pressure, and fuel quality.

The CALMET model was used to determine wind and temperature fields. For each road segment (see below for definition of road segments used in the model), an hourly data set representing one year of data was generated and formatted for input into the CALINE model. Roughness length, required by the model and used to indicate turbulence characteristics of a particular type of surface, was presumed to be 100 cm.

For modelling and emission estimation purposes, the Project is divided into the following six segments:

- Segment 1: Bridgeport Road to Westminster Highway
- Segment 2: Westminster Highway to Steveston Highway
- Segment 3: Tunnel/new bridge and approaches
- Segment 4: Highway 17A to Highway 17
- Segment 5: Highway 17 to Ladner Trunk Road interchange
- Segment 6: Ladner Trunk Road interchange to Highway 91 (Delta)

Traffic Data

A range of future traffic scenarios in terms of tolling, traffic volumes, and congestion levels were considered, and the most conservative scenario was used in predicting future emissions. As discussed in Section 5.1.2.4 of the Application, average annual daily traffic volumes (AADT) for 2030 were assessed using TransLink’s RTM for two scenarios– with the new bridge in place and no tolls being applied (TL-RTM Untolled), and with a new tolled bridge in place (TL-RTM Tolled). Given the variability in the forecasting, and to ensure a conservative assessment for EA purposes, the upper range of forecast values (TL-RTM untolled, 2030 With the Project) were used as it represents the highest potential volume of traffic.

4.9.1.3 Assessment Boundaries

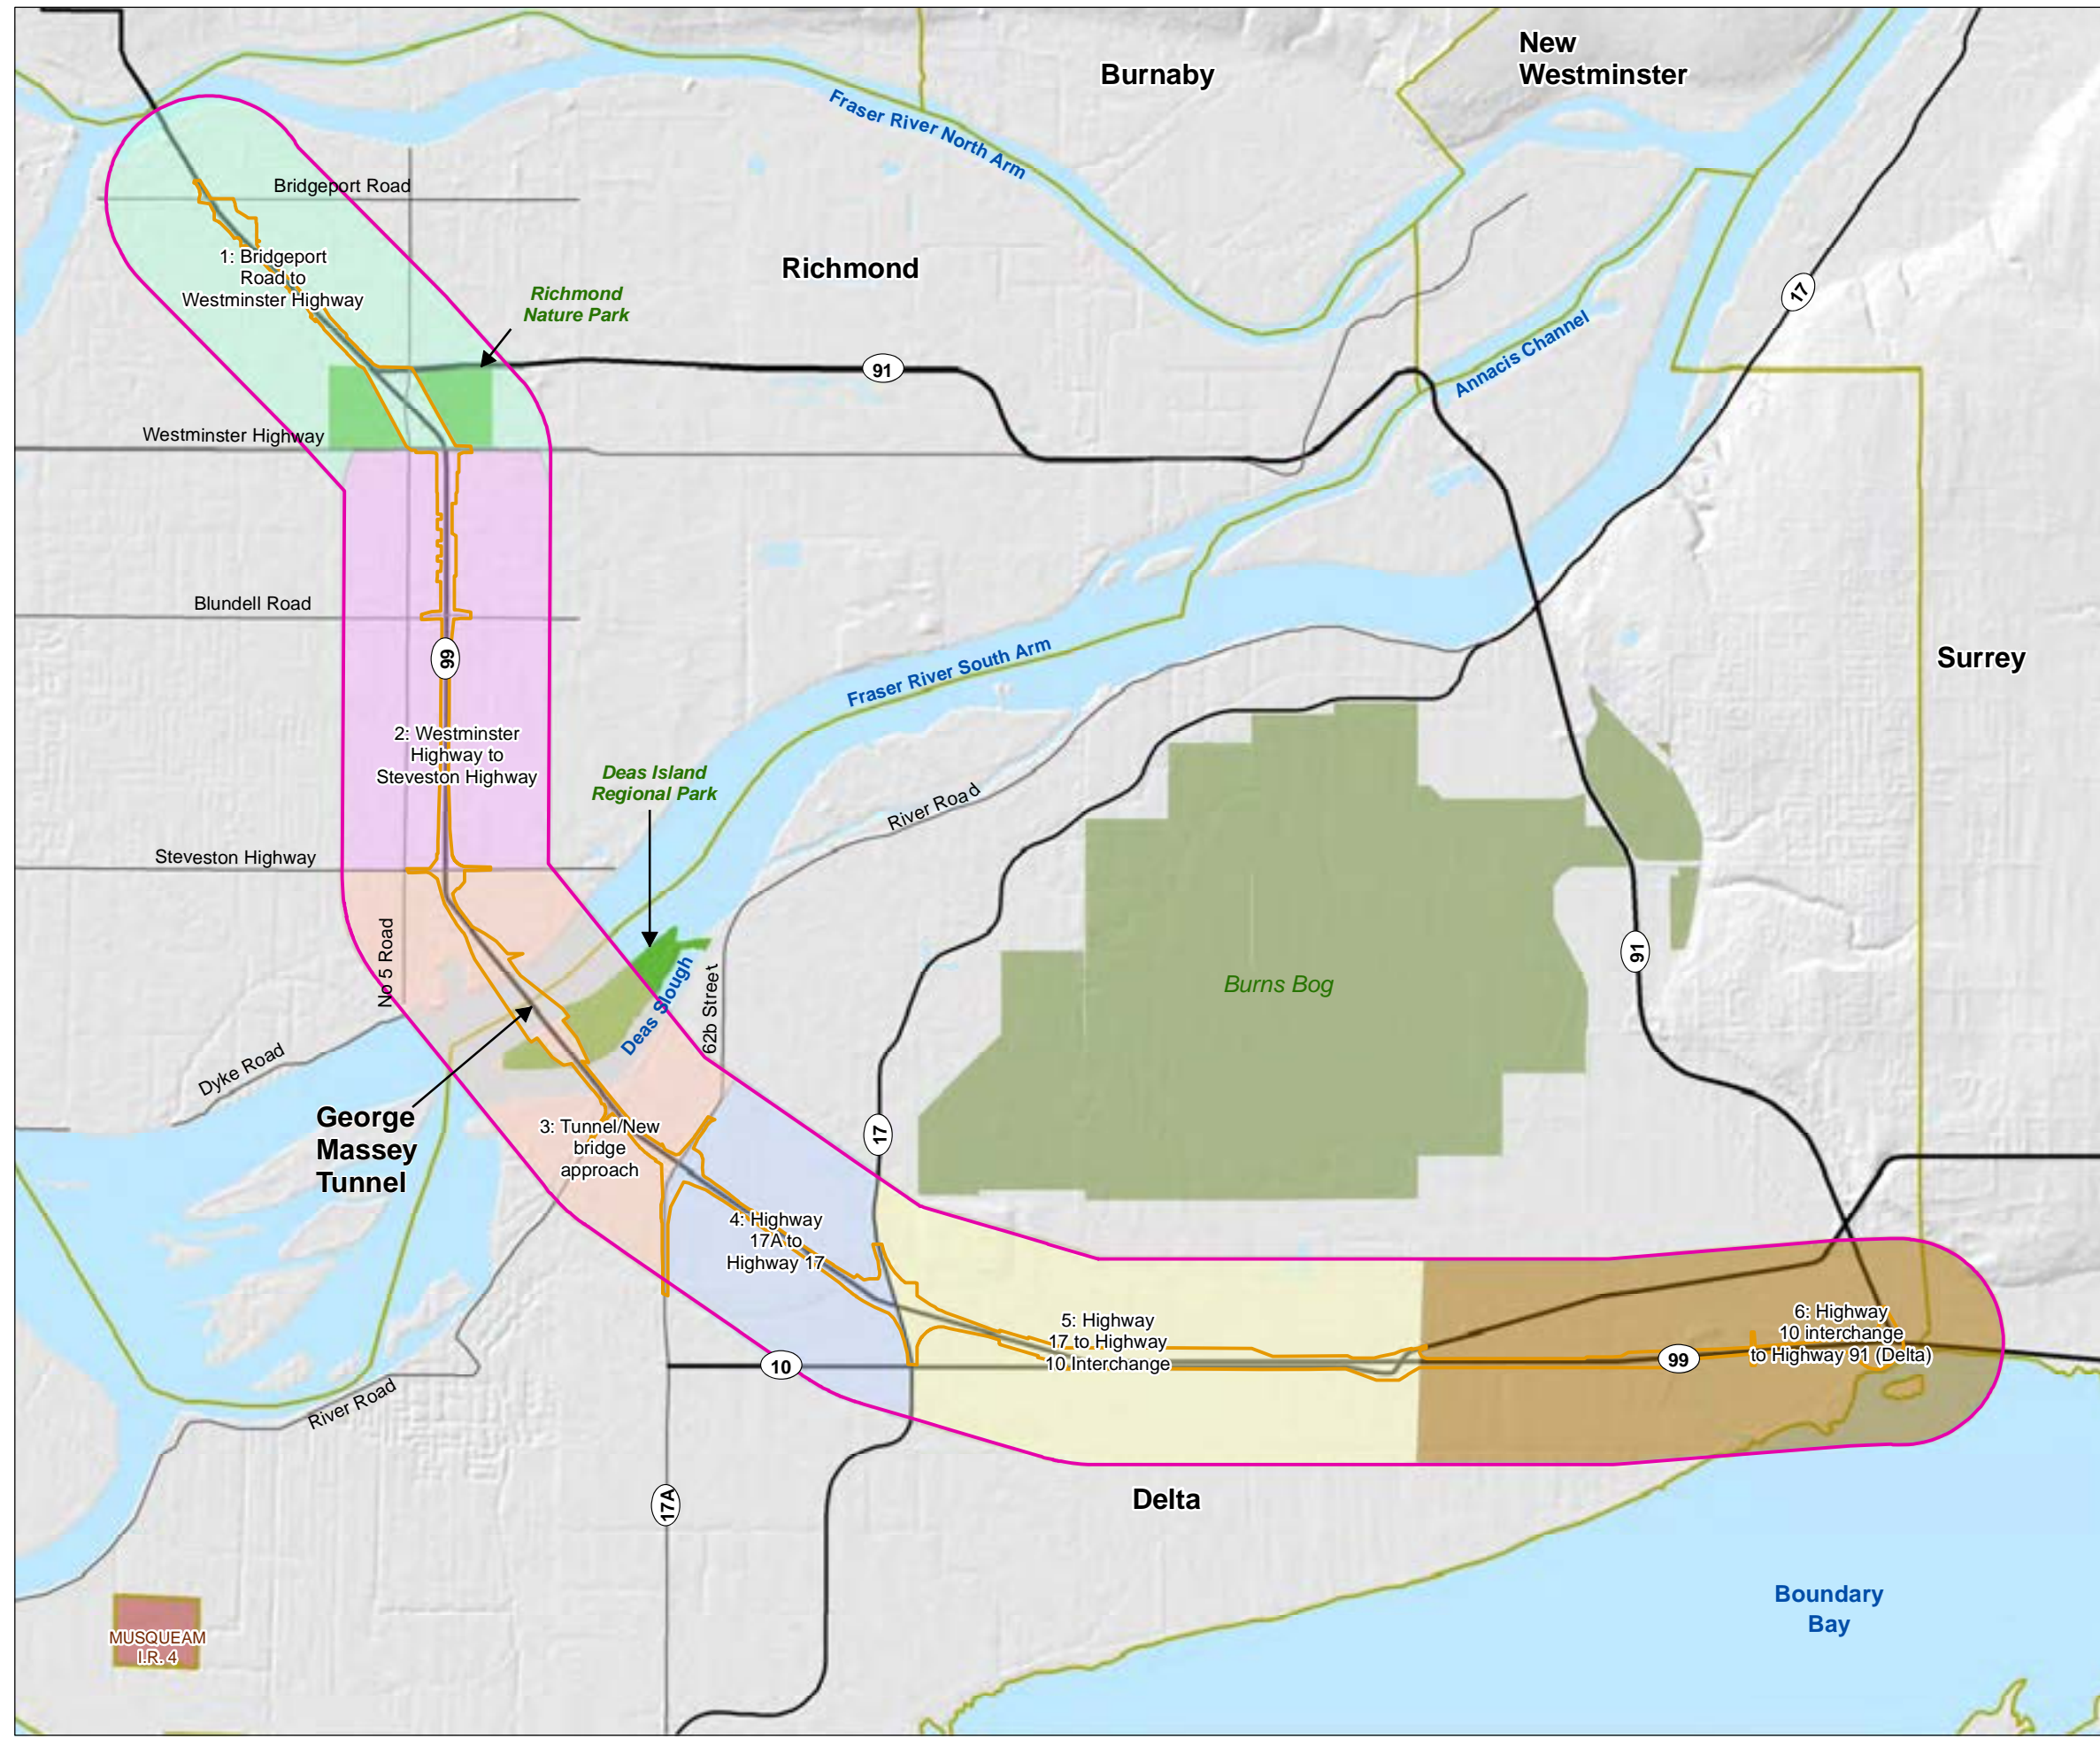

The assessment boundaries for air quality are defined below.

Spatial Boundaries

The local assessment area (LAA) and regional assessment area (RAA) for air quality is defined in **Table 4.9-2**, and shown on **Figure 4.9-1** and **Figure 4.9-2**, respectively.

Table 4.9-2 Spatial Boundaries for Air Quality Assessment

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|--|
| Local Assessment Area (LAA) | The area within a one-kilometer wide corridor, extending 500 m from either side of the Highway 99 centerline, over the length of the Project alignment – from Bridgeport Road (Richmond) to Highway 91 (Delta) including interchanges. |
| Regional Assessment Area (RAA) | The lower Fraser Valley airshed defined as the area bounded to the north by North Vancouver, to the east by Hope, and to the south by the Cascade Mountains in Washington State |

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on air quality were established based on the potential for each phase of the Project to interact with and have an effect on air quality. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, both the construction and operation phase of the Project include components and activities that could interact with and affect air quality; therefore, the following temporal boundaries were defined for air quality assessment:

- Existing conditions.
- Construction phase (including decommissioning of the Tunnel).
- Operations phase (new bridge and highway in operation).

Temporal characteristics (timing) of the Project construction phase (including decommissioning of temporary construction-related facilities and the Tunnel), and operation phases are defined in **Section 1.1.3 Project Phases and Schedule**. To better understand existing conditions and support the assessment of potential effects of the Project on human health, three emission scenarios were modelled:

1. Existing (2011) conditions
2. Future (2031) conditions without the Project (i.e., no new bridge, Tunnel operational)
3. Future (2031) conditions with the Project (i.e., post-construction, new bridge operational, Tunnel decommissioned)

The year 2011 was selected to represent existing conditions because it is the most recent year for which traffic modelling data and Metro Vancouver's emissions inventory were available at the time of modelling. 2031 was selected to represent what is reasonably foreseeable for forecasting emissions into the future, and to coincide with the regional emission inventory forecast.

Administrative Boundaries

No political, economic, or social constraints that could impose limitations on the assessment of potential Project-related effects on air quality have been identified; therefore, no administrative boundaries are defined.

Technical Boundaries

Vehicular and construction emissions are quantified using default emission factors¹ and modelling tools. Dispersion modelling provides a worst-case estimate of the potential effects of emissions sources on the surrounding air quality, and results of assessment based on dispersion modelling may be conservative in nature.

4.9.2 Existing Conditions

This section discusses anticipated interactions of Project components and activities with air quality, and potential effects of such interactions on criteria air contaminants, road dust, and toxic air contaminants. Information on mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 4.9.4**. Potential residual effects (i.e., effects remaining following the implementation of mitigation measures) are described in **Section 4.9.5**. A discussion of the potential for cumulative effects on air quality is presented in **Section 4.9.6**.

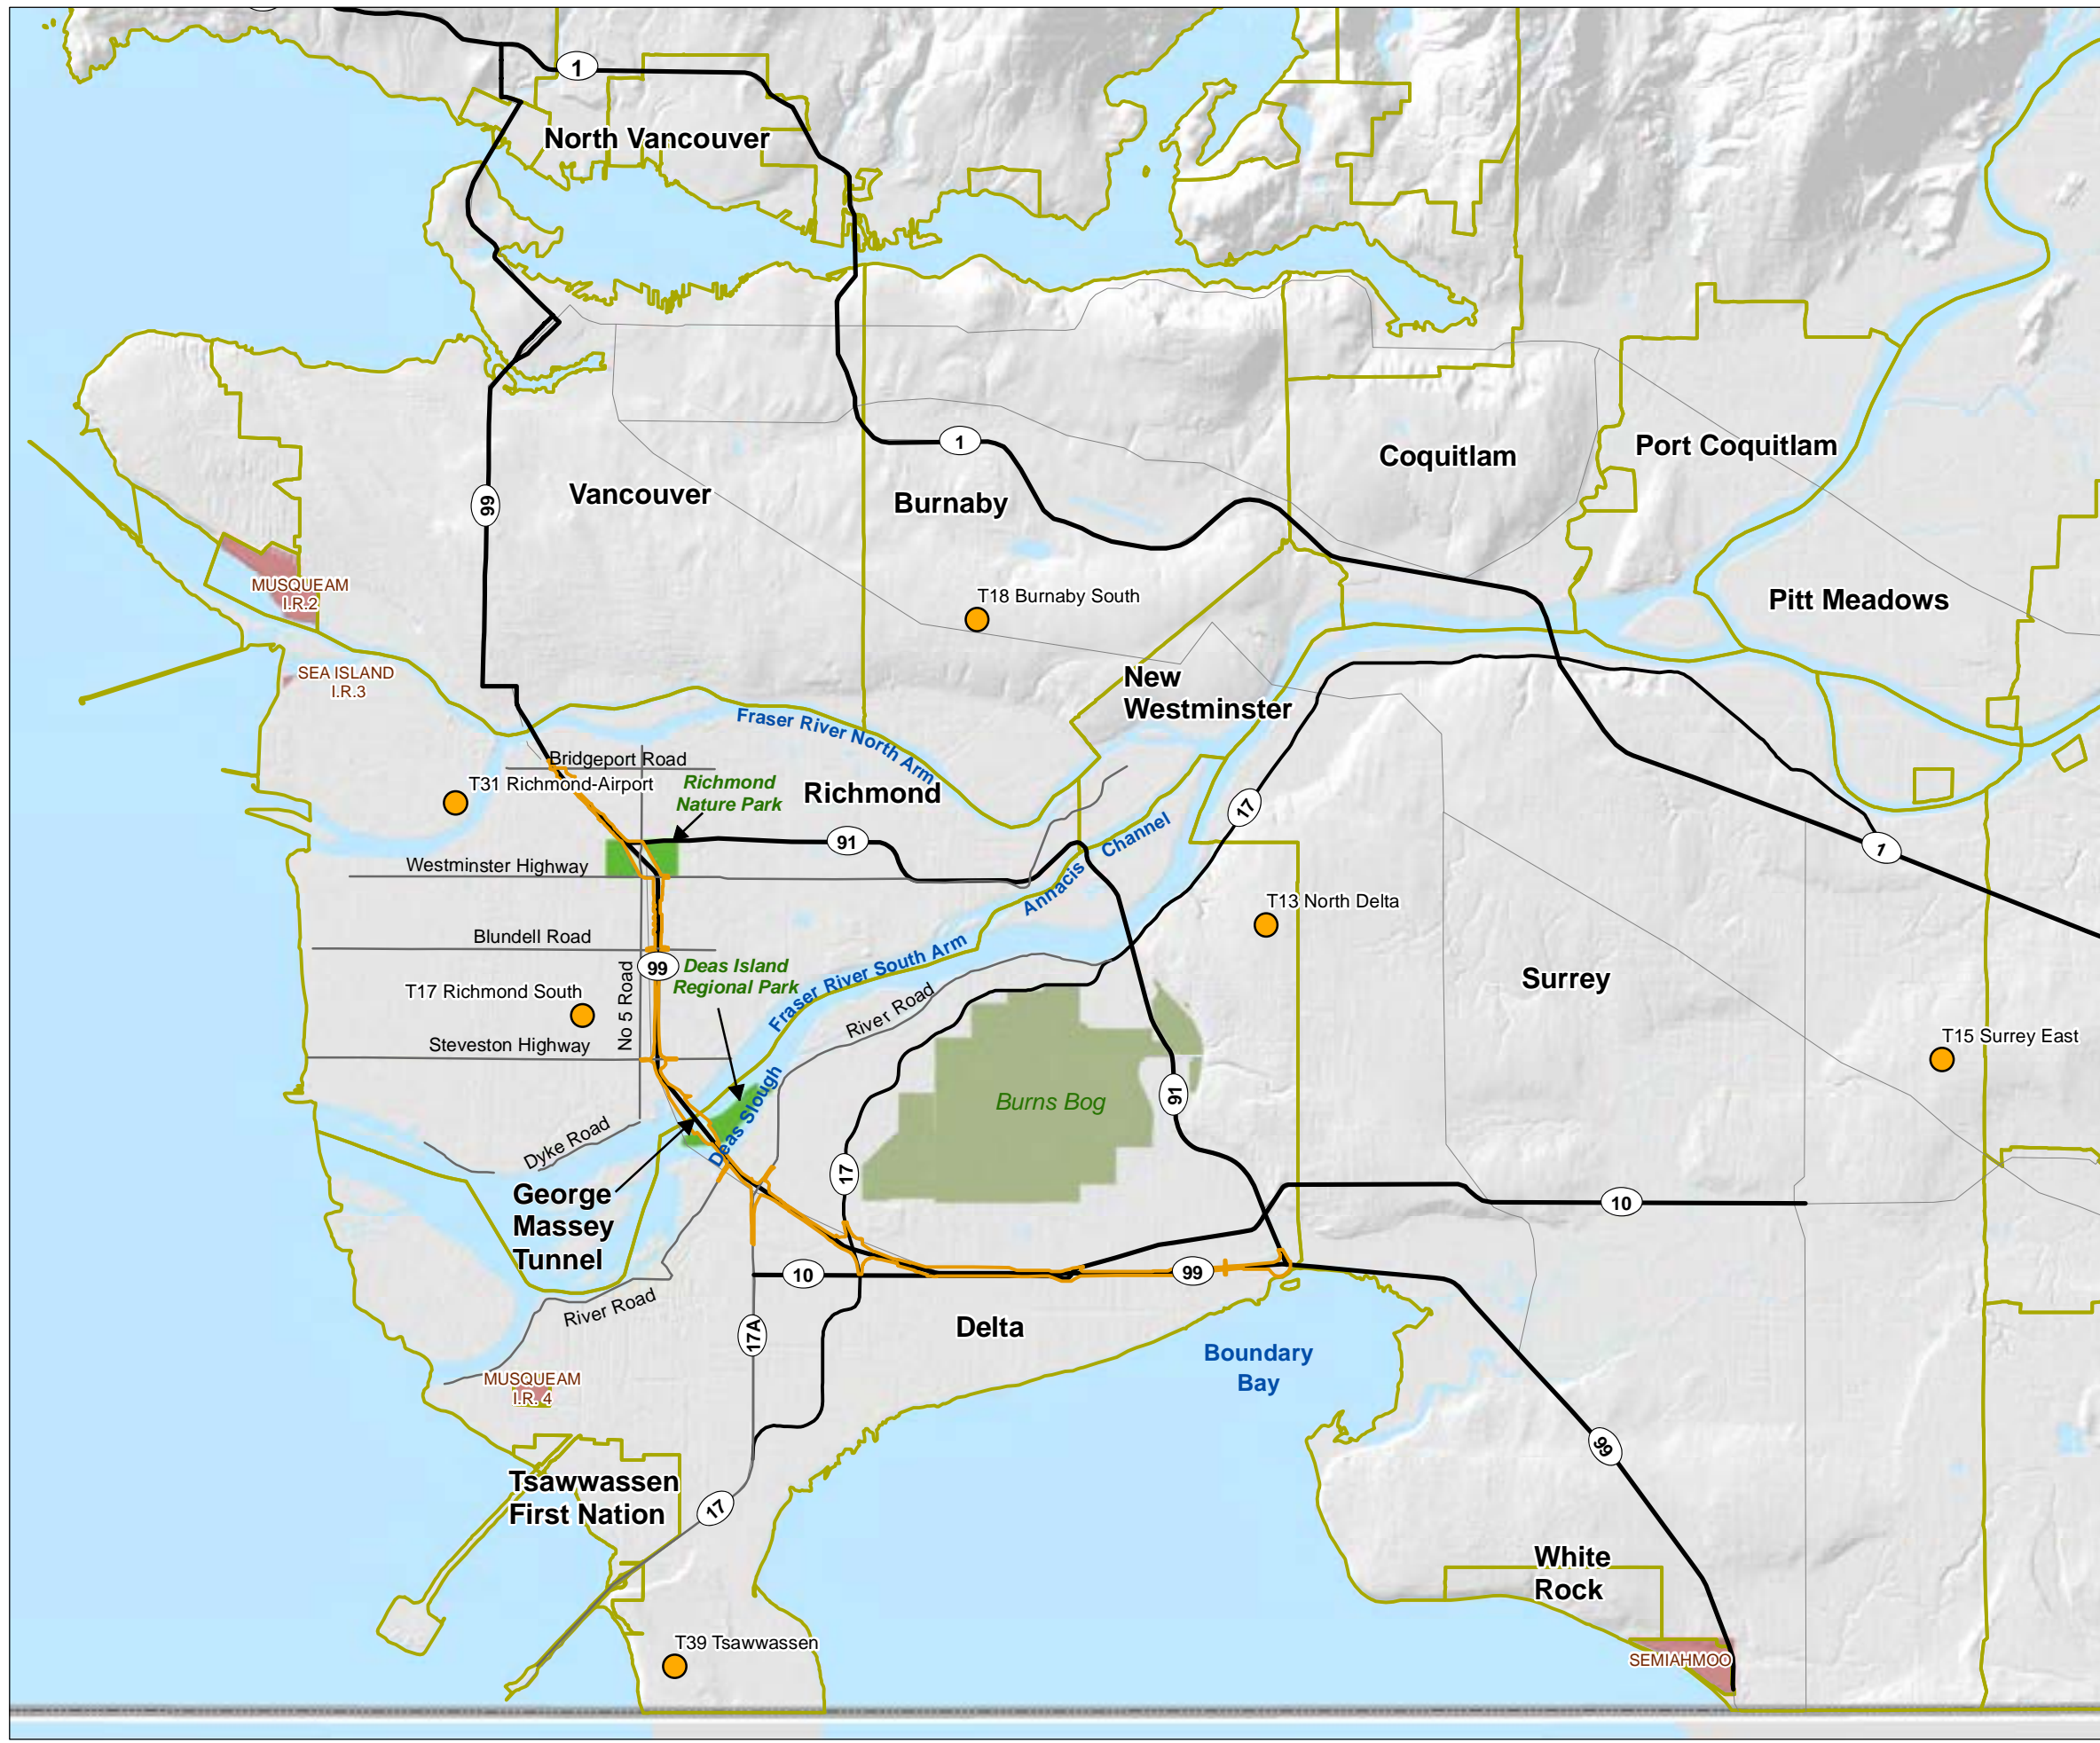

4.9.2.1 Baseline Data Collection

Ambient Air Quality

Ambient air quality for the LAA was characterized using data provided by Metro Vancouver at six monitoring stations (**Figure 4.9-3**) located within 20 km of the Project. Ambient air quality data cover the period from 2008 to 2012, and represent the highest 98th percentile (i.e., value at or below which 98% of the data fall). Data were compared to provincial, federal, or regional Ambient Air Quality Objectives (AAQOs) to determine potential Project-related changes on local air quality. Data on TACs were obtained from the National Air Pollution Surveillance network.

¹ An emission factor is defined as the average emission rate of a given pollutant for a given source, relative to units of activity (e.g., kg of SO₂ emitted per kilometre travelled).

Meteorology and Climatology

Local meteorology is a strong determinant of local air quality since it is the primary driver of dispersion of pollutants within an airshed. Data on wind speed, wind direction, and ambient temperature relevant to the Project were obtained from the Vancouver International Airport station (T31 Richmond-Airport, **Figure 4.9-3**), and compared with long-term climate data from Metro Vancouver stations to select a baseline year representative of the region's climatology. Based on this analysis, the year 2012 was used in modelling studies conducted for this assessment (**Section 4.9.3.2**). Datasets for wind speed, wind direction, and ambient temperature from the six ambient air monitoring stations were used to determine data suitability for modelling. A three-dimensional meteorological model for determining wind and temperature fields, CALMET, was used to characterize the meteorology near each modelled road segment from January 1, 2012 to December 31, 2012.

Vehicle Emissions

Vehicle emission factors were determined using the United States Environmental Protection Agency (US EPA) Motor Vehicle Emissions Simulator (MOVES 2010b) computer modelling program, described in **Section 4.9.3.2**.

The B.C. Modelling Guideline, which outlines recommended steps (e.g. development of a conceptual as well as a detailed model plan) for completing modelling projects, was used to guide Project-related air-quality modelling. Metro Vancouver was involved in the model planning discussions from the early stages of model planning, and this consultation helped identify and address some of the issues noted in this assessment.

Model input data were provided by Metro Vancouver and included the following:

- Climate data.
- Fleet age distribution and profile (i.e., proportion of vehicle types) (Metro Vancouver 2013).
- Information on inspection and maintenance programs and regulatory framework (e.g., BC renewable fuel requirement of five per cent for gasoline and four per cent for diesel).
- Vancouver-specific fuel sales and fuel characteristics (e.g., Reid vapour pressure, ethanol blend market share, biodiesel content).

Road Dust

Road dust emissions were quantified using methodology developed by US EPA (2011), as described in **Section 3.2.3** of the technical volume, *Air Quality Study*, included under **Section 16.5**. Data input included highway silt content and vehicle fleet average weight obtained from Metro Vancouver, and number of precipitation days collected for 2011 from station T17 Richmond South (**Figure 4.9-3**).

Traffic Data

Pollutant emissions are dependent on the amount of traffic moving through a given roadway. Results of travel demand forecasting, completed in support of Project planning and design using the travel demand modelling system EMME/2, were used to estimate the volume of traffic expected along the Project corridor in the future (2031).

4.9.2.2 Regulatory Context

This section provides an overview of federal, provincial, and regional ambient air quality objectives (AAQOs) that are relevant to the Project.

Federal

The federal government's role in addressing air quality issues is largely defined through the *Canadian Environmental Protection Act (CEPA)*, 1999, SC 1999, c. 33. Many emission sources that lie beyond provincial authority are subject to federal regulation, standards, and guidelines. These include motor vehicles and fuels, marine vessels, railways, and off-road engines.

Provincial

The provincial *Environmental Management Act*, SBC 2003, c. 53, provides the Minister of Environment with the authority to develop objectives to manage air quality in B.C. Air quality objectives are non-statutory limits (i.e., not legally binding) that are used to:

- Gauge current and historical air quality.
- Guide decisions on environmental impact assessments and authorizations.
- Guide airshed planning efforts.
- Inform regulatory development.
- Develop and apply episode management strategies such as air quality advisories.

Under provisions of the *Environmental Management Act*, Metro Vancouver has been delegated authority to manage air quality within its boundaries. A key role played by Metro Vancouver under this delegated authority is establishing ambient air quality criteria that may be different but no less stringent (or more stringent) than requirements established by the Province.

Air Quality Objectives

AAQOs are developed by environmental and health authorities and are based on scientific studies that consider the effects of the contaminants on such receptors as humans, wildlife, vegetation, as well as aesthetic qualities such as visibility.

The current provincial, federal, and regional (Metro Vancouver) AAQOs for NO₂, CO, SO₂, PM₁₀, and PM are shown in **Table 4.9-3**. Emissions of NO₂, CO, SO₂, and PM are relevant to the assessment because of Project construction and operation activities which will result in contaminants being directly emitted in the form of construction equipment and vehicle exhaust. Management of ground level ozone is a key priority for Metro Vancouver, and the Project will support Metro Vancouver's Regional Ground Level Ozone Strategy by facilitating a reduction in VOC emissions in the Western portion of the Lower Fraser Valley (Policy Directions A3, B1, B2, and B3). The objectives for ozone (O₃) have also been included in **Table 4.9-3** because O₃ is formed as a secondary contaminant by a photochemical reaction that occurs in the atmosphere between NO_x and VOCs. NH₃ is also included in **Table 4.9-3**, as NH₃ is expected to be emitted during project construction and operation. No AAQOs exist for NH₃ in B.C.; therefore, the Ontario 24-hour guideline of 100 µg/m³ (Ontario Ministry of the Environment 2012) was adopted for comparison purposes in this assessment. Toxic air contaminants AAQOs that are relevant to the Project are discussed below.

Federal National Ambient Air Quality Objectives (NAAQOs) are classified into three categories of maximum desirable, maximum acceptable, and maximum tolerable concentrations; the maximum desirable objective is the most stringent standard. Provincial objectives for some pollutants have multiple levels (e.g., A, B, and C) reflecting the different conditions under which the objectives may be applied. For additional details, refer to **Section 2.2** of the technical volume, *Air Quality Study*, included under **Section 16.5**. Over the past few years, most Provincial objectives have been reduced to a single number for each averaging period. For pollutants with multiple objectives, Level A objectives are the most stringent, typically applied to new and proposed discharges to the environment, and are usually the same as the federal maximum desirable objective. Metro Vancouver's AAQOs are medium-term, health-based, and are a step towards the lowest observable effects levels (Metro Vancouver 2015).

Canadian Ambient Air Quality Standards (CAAQS)—Canada-wide standards for fine particulate matter (PM_{2.5}) and ozone (CCME 2012), developed under Canadian Council of Ministers of the Environment (CCME), are part of the Air Quality Management System (AQMS). These standards are set for air sheds across the country and require compliance with the concept of continuous improvement and keeping clean areas where PM and ozone ambient levels fall below numeric standards (CCME 2012). The CAAQS for NO₂, CO, SO₂, PM₁₀, PM_{2.5}, and O₃ are provided in **Table 4.9-3**.

Table 4.9-3 Summary of Federal, Provincial, and Regional Ambient Air Quality Objectives for Criteria Air Contaminants

| Parameter | Federal Objective ¹ (µg/m ³) | | | Provincial Objective ² (µg/m ³) | | | Regional Objective ³ (µg/m ³) | Most stringent objective (µg/m ³) |
|-------------------------|---|---------------------------------|--------------------------------|--|----------------------|----------------------|--|---|
| | Maximum Desirable ⁴ | Maximum Acceptable ⁴ | Maximum Tolerable ⁴ | Level A ⁵ | Level B ⁵ | Level C ⁵ | | |

n/a Objective not applicable

British Columbia does not have AAQOs for the TACs listed in **Section 4.9.1.2**, except for the one-hour average objective for formaldehyde (60 µg/m³). The Alberta Ambient Air Quality Objectives (Alberta Environment and Sustainable Resource Development 2013) and the Ontario Ambient Air Quality Criteria (AAQC) (Ontario Ministry of the Environment 2012) listed in **Table 4.9-4**, are used in this assessment for TACs other than formaldehyde. In the case where standards exist for both Alberta and Ontario (i.e. annual averaging period for benzene and benzo(a)pyrene), the more stringent standard is applied.

Table 4.9-4 Ambient Air Quality Objectives for Toxic Air Contaminants

| Toxic Air Contaminants | Averaging Period | British Columbia AAQO (µg/m ³) | Alberta AAQO (µg/m ³) | Ontario AAQC (µg/m ³) |
|------------------------|------------------|--|-----------------------------------|-----------------------------------|
| Acrolein | 1-hour | n/a | 4.5 | n/a |
| | 24-hour | n/a | n/a | 0.4 |

| | Annual | n/a | n/a | 2 |

Notes: AAQO=Ambient Air Quality Objectives; AAQC=Ambient Air Quality Criteria; n/a=Objective not applicable.

4.9.2.3 Existing Conditions

This section describes existing conditions pertaining to air quality within the LAA, based on background air quality data analysis, and traffic and emissions model outputs. The results of dispersion modelling, undertaken for this assessment, are also summarized to offer an insight into what future (2031) air quality conditions might be in the RAA with and without the Project.

Vehicle Emissions

Annual vehicle emissions of CACs and TACs for the existing (2011) condition scenario are shown in **Table 4.9-5**. These values are based on 2011 traffic volumes and existing road infrastructure. These results were used as the base for comparison for vehicle emissions in 2031, with and without the Project.

Table 4.9-5 Vehicle Emissions from Highway 99 Traffic Within the Project Alignment – Existing (2011) Condition

| Parameters | Vehicle Emissions (tonnes/year) |
|------------------------------|---------------------------------|
| CACs | |
| VOCs | 234.4 |
| Carbon monoxide | 3,594.5 |
| Nitrogen oxides | 388.4 |
| Sulphur dioxide | 2.7 |
| Ammonia | 11.8 |
| PM (vehicles) | 14.9 |
| PM ₁₀ (vehicles) | 14.9 |
| PM _{2.5} (vehicles) | 11.0 |
| Road Dust | |
| PM | 279.5 |
| PM ₁₀ | 53.6 |
| PM _{2.5} | 13.0 |
| TACs | |
| Diesel PM | 4.1 |
| Benzene | 7.8 |
| Naphthalene | 0.5 |
| 1,3-butadiene | 0.8 |
| Formaldehyde | 2.8 |
| Acetaldehyde | 2.4 |
| Acrolein | 0.2 |
| Benzo(a)pyrene | 0.0008 |

Notes: n/a = Objective not applicable

Ambient Air Quality

Table 4.9-6 shows the results of the CALINE dispersion modelling for the existing (2011) conditions scenario. Maximum and 98th percentile emissions are presented for the estimated one-hour, 24-hour, and annual ambient concentrations for each contaminant. The 98th percentile is the value that ambient concentrations are equal to or less than 98% of the time. The 98th percentile values are important to consider, along with the maximum concentration, because maximum values can often be considered an anomaly, whereas the 98th percentile provides a better representation of maximum effects of the Project on local air quality. Shaded cells indicate an exceedance of the relevant, most stringent AAQOs. Since only one year of dispersion modelling was conducted, 98th percentile values were not estimated for the annual averaging period.

Table 4.9-6 Estimated Maximum and 98th Percentile Concentrations ($\mu\text{g}/\text{m}^3$) of Pollutants of Concern – Existing Conditions

| Pollutant | Averaging Period | Maximum Concentration ($\mu\text{g}/\text{m}^3$) | 98 th Percentile Concentration ($\mu\text{g}/\text{m}^3$) | Ambient Air Quality Objective ($\mu\text{g}/\text{m}^3$) |
|------------------------------------|------------------|--|--|--|
| VOCs | 1-hour | 2,796.7 | 1,167.9 | n/a |
| | 24-hour | 256.3 | 162.2 | n/a |
| | Annual | 73.4 | n/a | n/a |
| Carbon monoxide | 1-hour | 20,325.1 | 8,616.0 | 14,300 |
| | 8-hour | 4,980.6 | 2,491.8 | 5,500 |
| Nitrogen dioxide (100% conversion) | 1-hour | 2,574.1 | 1,086.0 | 188 |
| | Annual | 92.8 | n/a | 40 |
| Sulphur dioxide | 1-hour | 27.6 | 11.6 | 196 |
| | 24-hour | 2.7 | 1.7 | 125 |
| | Annual | 0.8 | n/a | 25 |
| Ammonia | 24-hour | 11.0 | 6.9 | 100 |
| PM ₁₀ (Vehicles) | 24-hour | 19.5 | 12.4 | 50 |
| | Annual | 5.6 | n/a | 20 |
| PM _{2.5} (Vehicles) | 24-hour | 12.1 | 7.6 | 25 |
| | Annual | 3.5 | n/a | 8 |

| Pollutant | Averaging Period | Maximum Concentration ($\mu\text{g}/\text{m}^3$) | 98 th Percentile Concentration ($\mu\text{g}/\text{m}^3$) | Ambient Air Quality Objective ($\mu\text{g}/\text{m}^3$) |
|-------------------------------|------------------|--|--|--|
| PM ₁₀ (Road Dust) | 24-hour | 37.1 | 23.1 | 50 |
| | Annual | 11.7 | n/a | 20 |
| PM _{2.5} (Road Dust) | 24-hour | 9.0 | 5.6 | 25 |
| | Annual | 2.8 | n/a | 8 |
| Benzene | 1-hour | 58.0 | 24.4 | 30 |
| | 24-hour | 6.9 | 4.3 | 2.3 |
| | Annual | 2.0 | n/a | 0.45 |
| Naphthalene | 24-hour | 0.5 | 0.3 | 22.5 |
| 1,3-Butadiene | 24-hour | 0.7 | 0.4 | 10 |
| | Annual | 0.2 | n/a | 2 |
| Formaldehyde | 1-hour | 26.3 | 11.0 | 60 |
| Acetaldehyde | 1-hour | 18.1 | 7.6 | 90 |
| | 24-hour | 2.1 | 1.3 | 500 |
| Acrolein | 1-hour | 1.7 | 0.7 | 4.5 |
| | 24-hour | 0.2 | 0.1 | 0.4 |
| Benzo(a)pyrene | 24-hour | 8.9E-04 | 5.7E-04 | 5.00E-05 |
| | Annual | 2.6E-04 | n/a | 1.00E-05 |

Notes: n/a = Objective not applicable. Shaded cells indicate an exceedance of the relevant, most stringent AAQOs.

Currently, carbon monoxide, nitrogen dioxide, benzene, and benzo(a)pyrene exceed the most stringent AAQOs. The one-hour 98th percentile of carbon monoxide concentrations does not exceed the objective of 14,300 $\mu\text{g}/\text{m}^3$; therefore, carbon monoxide is estimated to exceed the one-hour AAQO less than 0.2% of the time. While nitrogen dioxide is predicted to exceed the most stringent AAQO of 188 $\mu\text{g}/\text{m}^3$, the NO₂ concentrations are based on 100% conversion of NO_x, which is extremely conservative.

4.9.3 Potential Effects

This section provides a summary of anticipated changes to air quality related to the construction and operation of the Project. It also describes the methodology used to assess potential Project-related effects.

4.9.3.1 Project Interactions

A preliminary evaluation of the potential effects of Project interactions on air quality, intended to focus the assessment on interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Construction: Project construction will interact with air quality through air emissions from road dust and fuel combustion in diesel, propane, and gasoline-powered machinery, equipment, and vehicles operating during highway upgrades and new bridge construction.

Operation: During Project operation, the traffic pattern, volume, and vehicle fleet composition is expected to result in changes in emissions associated with the Highway 99 corridor. Potential interactions of Project-related operations with air quality include:

- Operating reconfigured Highway 99 and interchanges.
- Operating the new bridge.

Maintenance activities associated with Project operations are not anticipated to interact with air quality as these activities generally produce minute amounts of vehicle emissions that would be too small to detect.

An overview of potential interactions between Project activities and air quality during the construction and operation of Project components is provided in **Appendix A**.

4.9.3.2 Potential Effects

The following basic steps were followed to assess potential Project-related changes in air quality:

- Estimate air contaminant emissions from vehicles and road dust for the three scenarios of existing (2011), future (2031) without the Project, and future (2031) with the Project through emissions modelling.
- Use the estimated emission values to predict contaminant concentrations in air within the LAA for the three scenarios through dispersion modelling.
- Compare estimated concentrations with applicable AAQOs to identify potential exceedances.
- Compare estimated pollutant concentrations within the LAA for the two future (2031) scenarios against existing (2011) conditions to predict potential Project-related changes.

The future conditions were assessed using the reference year 2031 to make effective use of the vehicle fleet emissions forecasts set out by Metro Vancouver, and the Regional Transportation Model. An overview of emissions modelling conducted to estimate contaminant emissions and dispersion modelling completed to predict contaminant concentrations is provided below. Additional details on the modelling methods used to support the assessment of air quality are provided in **Section 3.3** of the technical volume, *Air Quality Study*, included under **Section 16.5**.

Emissions Modelling

Vehicle emission factors were determined for 13 vehicle and three fuel (i.e., gasoline, diesel, and compressed natural gas) types, using MOVES2010b. The MOVES model accounts for changes in emissions caused by changes in vehicle emissions standards, vehicle populations and activities, and variation in local conditions (e.g., temperature, humidity, pressure, and fuel quality). Emission factors for each vehicle type were determined for a variety of vehicle speeds for pollutants listed in **Section 4.9.1.2**.

Traffic information was derived from an emissions inventory developed for the Project based on vehicle kilometre travelled (VkmT) for each vehicle category and vehicle class-specific emission factors. Traffic modelling data for all three scenarios, within the LAA, were broken down into vehicle type, based on Metro Vancouver's current and forecasted fleet profiles.

For each segment of road, the number of vehicles by type and associated emission factor were multiplied together to determine an emission rate per kilometre of road per vehicle. The dispersion model (see discussion on Dispersion Modelling below) used emission rates, road length, width, and orientation to predict ambient air quality resulting from traffic flowing on each of the six road segments. Details on the vehicle emissions factors modelling are provided in **Section 3.2.2** of the technical volume, *Air Quality Study*, included under **Section 16.5**.

Quantification of Road Dust Emissions

Road dust emissions are not generated by the MOVES model, but are considered within the scope of this study. Road dust quantification followed the methods developed by U.S. EPA (2011) and is described in detail in **Section 3.2.3** of the technical volume, *Air Quality Study*, included under **Section 16.5**.

Dispersion Modelling

Dispersion modelling was conducted for existing (2011) conditions and future (2031) conditions, with and without the Project, using CALINE3 combined with CALMET, to predict concentrations of emission-related contaminants in ambient air. CALINE predicts hourly ambient concentrations at designated receptor locations, represented as grid points with Universal Transverse Mercator (UTM) coordinates. Receptors in this study were spaced along Highway 99 at 100 m intervals and extended at intervals of 5, 10, 15, 20, 25, 50, 100, 250, 500 and 1,000 m perpendicular to the road. In addition, sensitive receptors (e.g., schools, hospitals) were included in the CALINE receptor grid. (See **Figure 1** of the technical volume, *Air Quality Study*, included under **Section 16.5** for details). The air quality predictions from dispersion modelling were compared to the most stringent of applicable federal, provincial, or regional AAQOs (**Table 4.9-3**).

Potential Construction Effects

Emissions associated with Project construction are not quantifiable at this time as the contractor has not been selected and the exact age and type of equipment that would be used in construction is not known. However, it is anticipated that the equipment fleet used on the Project will be similar to those used on previous transportation infrastructure projects in the region, as summarized in **Table 4.9-7**.

Table 4.9-7 Construction Fleet Parameters

| Equipment Type | Horsepower |
|----------------------------|------------|
| Loaders | 300 |
| Crawler tractors | 468 |
| Excavators | 286 |
| Graders | 275 |
| Haul Units – Off – Highway | 1,000 |
| Highway Trucks – Hauling | 510 |
| Compactors | 107 |
| Hydraulic excavators | 286 |
| Support equipment | 125 |

The following types of emissions are expected from Project-related construction activities: fugitive dust associated with soil stockpiles and ground disturbance; and common air contaminants (such as NO_x, SO_x, VOCs) generated by fuel combustion in construction equipment. Based on results of air quality monitoring and analysis on previous projects in the Lower Mainland, specifically the South Fraser Perimeter Road/Highway 17 project, overall construction-related emissions due to the Project are expected to be immaterial in relation to the amount of emissions occurring along the corridor.

Air quality monitoring was conducted before, during, and after the construction of many of the major infrastructure projects, and in each case monitoring results were summarized in monitoring and analysis reports submitted to regulatory agencies. Documented monitoring results, including a five year record (2009 to 2013) of monitoring particulate matter and dustfall for SFPR (the project closest to Highway 99), have demonstrated that the air quality management and dust control plans, similar to those that will be implemented for the Project, were effective in addressing potential construction-related effects on air quality and ensuring applicable air quality objectives were met. The monitoring period covered the phases pre-construction, construction, and post operation, and the data shows that there was no appreciable difference in air quality between any of the phases, which provides further evidence that influence of construction activities on air quality is immaterial when compared to other activities that influence air quality in the corridor.

Air quality is currently monitored in Richmond and Delta, and air quality monitoring will be undertaken at construction site(s) during the Project construction period to verify that construction-related emissions do not have any material effect on air quality in the area. Construction-related air quality monitoring will also be used to ensure best management practices are being followed and air quality objectives are being met. Reports summarizing results of air quality monitoring and analysis will be provided to relevant stakeholder agencies.

Potential Operation Effects

Vehicle Emissions

Table 4.9-8 presents predicted emissions of CACs, road dust, and TACs in the LAA for the two future scenarios. The 2031 scenario with the Project considers the untolled, worst-case operational phase of the Project while the other (2031 without the Project) assumes that no road improvements have been made. Vehicle emissions for the two future scenarios (i.e., 2031 with and without the Project) are compared with baseline emissions (**Section 4.9.2.3**) to assess potential changes in air quality. Existing vehicle emissions conditions are also shown for comparison, as are per cent change in emissions resulting from this comparison (**Table 4.9-8**).

Table 4.9-8 Vehicle Emissions for 2031 Without and With the Project

| Species | Emissions (tonnes/yr) | | | Change from 2011 (%) | | Difference between Future With and Without the Project (%) |
|-------------------------------|-----------------------|-----------------|--------------|----------------------|--------------|--|
| | Existing Roads | Without Project | With Project | Without Project | With Project | |
| | 2011 | 2031 | 2031 | | | |
| VOCs | 234.4 | 139.9 | 123.5 | -40% | -47% | -12% |
| CO | 3594.5 | 3216.5 | 3444.7 | -11% | -4% | 7% |
| NOx | 388.4 | 166.1 | 169.6 | -57% | -56% | 2% |
| SO ₂ | 2.7 | 2.8 | 2.6 | 4% | -2% | -6% |
| NH ₃ | 11.8 | 9.8 | 9.6 | -17% | -19% | -2% |
| PM (Vehicles) | 14.9 | 12.8 | 9.4 | -14% | -37% | -27% |
| PM ₁₀ (Vehicles) | 14.9 | 12.8 | 9.4 | -14% | -37% | -27% |
| PM _{2.5} (Vehicles) | 11.0 | 7.2 | 6.3 | -35% | -42% | -11% |
| Diesel PM | 4.1 | 0.4 | 0.4 | -89% | -91% | -18% |
| PM (Road Dust) | 279.5 | 345.4 | 383.2 | 24% | 37% | 11% |
| PM ₁₀ (Road Dust) | 53.6 | 66.3 | 73.5 | 24% | 37% | 11% |
| PM _{2.5} (Road Dust) | 13.0 | 16.0 | 17.8 | 24% | 37% | 11% |
| Benzene | 7.8 | 4.1 | 4.2 | -47% | -47% | 1% |
| Naphthalene | 0.5 | 0.3 | 0.3 | -44% | -46% | -3% |
| 1,3-Butadiene | 0.8 | 0.4 | 0.4 | -49% | -46% | 5% |
| Formaldehyde | 2.8 | 1.7 | 1.7 | -37% | -40% | -5% |
| Acetaldehyde | 2.4 | 1.3 | 1.3 | -44% | -43% | 1% |
| Acrolein | 0.2 | 0.1 | 0.1 | -47% | -50% | -5% |
| Benzo(a)pyrene | 8.4E-04 | 5.7E-04 | 5.9E-04 | -33% | -31% | 3% |

Notes: n/a = Objective not applicable

In general, vehicle emissions of most pollutants are predicted to be lower in 2031 than in 2011, with or without the Project. Although traffic volumes are projected to increase in 2031, emission factors in 2031 will have decreases that are enough to offset the increase in traffic.

The only pollutants projected to increase by 2031 are road dust and sulphur dioxide. Road dust emissions are dependent on VkmT, silt loading, vehicle fleet average weight, and precipitation days per year. These parameters are considered constant from 2011 to 2031, with the exception of VkmT. Therefore, without applicable mitigation, road dust emissions are projected to increase with the Project in a linear manner that is consistent with growth in traffic volume.

Emissions of sulphur dioxide are influenced by fuel quality. At the time of this assessment, no new fuel regulation is planned or known that would require lower sulphur fuels. As such, the increase in sulphur dioxide emissions is solely due to the number of vehicles entering the fleet resulting in higher overall fuel consumption. Although emission factors present a slight decrease from 2011 to 2031, this decrease is not enough to offset the anticipated increase in traffic volumes in future years. Sulphur dioxide emissions are lower in 2031 with the Project than without the Project due to lower levels of congestion expected as a result of the new bridge (i.e., rates of sulphur dioxide emissions increase with lower vehicle speeds associated with congestion). Overall, when compared with the other pollutants, sulphur dioxide emissions are low and thus do not present a notable concern.

Overall, greater reductions in most CAC and TAC emissions are evident in 2031 with the Project. This decrease is primarily due to congestion alleviation expected as a result of Project operation. The reduction in emission factors outweighs the increase in traffic volumes, with the exception of carbon monoxide, nitrogen oxides, benzene, 1,3-butadiene, acetaldehyde and benzo(a)pyrene.

Ambient Air Quality

Table 4.9-9 presents predicted concentrations of CACs and TACs associated with Highway 99 traffic in the Project alignment based on dispersion modelling results for the two 2031 scenarios (i.e., with and without the Project). For each pollutant, the most stringent AAQO is listed. For all pollutants except VOCs, predicted concentrations are presented for those averaging periods (i.e., 1-hour, 8-hour, 24-hour, or 1 year) that have AAQOs associated with them. There are no AAQOs for VOCs and formaldehyde. Predicted concentrations of these compounds averaged over 1 hour, 24 hours, and 1 year are presented to facilitate a comparison between future and current conditions.

Detailed results of dispersion modelling by pollutant are presented in Section 5.2 of the technical volume, ***Air Quality Study (Section 16.5)***. Section 5.3 of the technical volume includes details on how pollutant concentrations vary by location within the LAA.

Table 4.9-9 Contaminant Concentrations ($\mu\text{g}/\text{m}^3$) Associated with Highway 99 Traffic in 2031

| Pollutant | Averaging Period | 2031 Without Project | | 2031 With Project | | Most Stringent Objective |
|------------------------------------|------------------|-----------------------|-----------------------------|-----------------------|-----------------------------|--------------------------|
| | | Maximum Concentration | 98 th Percentile | Maximum Concentration | 98 th Percentile | |
| CACs | | | | | | |
| VOCs | 1-hour | 1,832.2 | 764.2 | 393.5 | 134.4 | n/a |
| | 24-hour | 193.7 | 123.1 | 49.4 | 32.9 | n/a |
| | Annual | 55.8 | n/a | 13.8 | n/a | n/a |
| Carbon monoxide | 1-hour | 17,500.5 | 7,422.3 | 10,977.6 | 3,758.8 | 14,300 |
| | 8-Hour | 4,470.6 | 2,348.2 | 2,439.8 | 1,222.7 | 5,500 |
| Nitrogen dioxide (100% Conversion) | 1-hour | 1,252.4 | 526.0 | 539.7 | 184.0 | 188 |
| | Annual | 45.4 | n/a | 18.6 | n/a | 40 |
| Sulphur dioxide | 1-hour | 29.9 | 12.5 | 8.3 | 2.8 | 196 |
| | 24-hour | 3.3 | 2.2 | 1.0 | 0.7 | 125 |
| | Annual | 1.0 | n/a | 0.3 | n/a | 25 |
| Ammonia | 24-hour | 10.5 | 6.9 | 3.8 | 2.5 | 100 |
| PM ₁₀ (vehicles) | 24-hour | 23.1 | 15.3 | 3.8 | 2.5 | 50 |
| | Annual | 6.8 | n/a | 1.1 | n/a | 20 |
| PM _{2.5} (vehicles) | 24-hour | 9.6 | 6.4 | 2.5 | 1.7 | 25 |
| | Annual | 2.8 | n/a | 0.7 | n/a | 8 |
| Road Dust | | | | | | |
| PM ₁₀ | 24-hour | 45.1 | 29.2 | 29.5 | 19.6 | 50 |
| | Annual | 14.2 | n/a | 8.1 | n/a | 20 |
| PM _{2.5} | 24-hour | 10.9 | 7.1 | 7.1 | 4.7 | 25 |
| | Annual | 3.4 | n/a | 2.0 | n/a | 8 |

| Pollutant | Averaging Period | 2031 Without Project | | 2031 With Project | | Most Stringent Objective |
|----------------|------------------|-----------------------|-----------------------------|-----------------------|-----------------------------|--------------------------|
| | | Maximum Concentration | 98 th Percentile | Maximum Concentration | 98 th Percentile | |
| TACs | | | | | | |
| Benzene | 1-hour | 32.4 | 13.6 | 13.3 | 4.5 | 30 |
| | 24-hour | 4.0 | 2.6 | 1.7 | 1.1 | 2.3 |
| | Annual | 1.2 | n/a | 0.5 | n/a | 0.45 |
| Naphthalene | 24-hour | 0.3 | 0.2 | 0.1 | 0.1 | 22.5 |
| 1,3-Butadiene | 24-hour | 0.4 | 0.2 | 0.2 | 0.1 | 10 |
| | Annual | 0.1 | n/a | 0.0 | 4.9E-02 | 2 |
| Formaldehyde | 1-hour | 18.1 | 7.6 | 0.8 | 0.3 | 60 |

| Benzo(a)pyrene | 24-hour | 5.1E-04 | 3.3E-04 | 2.3E-04 | 1.6E-04 | 5.00E-05 |
| | Annual | 1.5E-04 | n/a | 6.4E-05 | n/a | 1.00E-05 |

Notes: n/a = Objective not applicable

The 2031 scenario without the Project is predicted to have more exceedances of AAQOs than the 2031 scenario with the Project. Without the Project, maximum concentrations of carbon monoxide, nitrogen dioxide, benzene, and benzo(a)pyrene associated with Highway 99 traffic in the Project alignment are predicted to exceed the most stringent AAQOs in 2031. Of note, the assessment for NO₂ concentrations is presented here. With the Project, no AAQO exceedances are predicted in 2031, except benzo(a)pyrene and the maximum 1-hour NO₂ concentration (presented here under the extremely conservative assumption of 100% conversion), both of which exhibit higher existing concentrations than predicted with the Project improvements.

In general, future air quality conditions without the Project are predicted to improve compared to existing conditions as a result of improvements to vehicle emissions through more stringent regulations, technology, and vehicle fleet turnover. Even with an increase in traffic, the 2031 scenario with the Project is predicted to result in an overall improvement in air quality compared to existing and future conditions without the Project.

4.9.4 Mitigation Measures

Mitigation measures developed to avoid or reduce potential adverse Project-related changes (e.g., during Project construction) and enhance improvements (e.g., during Project operation) to air quality are described in this section. A hierarchical approach based on avoidance of potential effects first, followed by minimization or reduction of unavoidable effects was used in identifying strategies to mitigate potential Project-related effects.

4.9.4.1 Avoidance

The new Fraser River crossing is proposed as an elevated structure, which will allow vehicle emissions to disperse rapidly and avoid effects on air quality associated with localized accumulation of pollutants.

4.9.4.2 Minimization

Measures to minimize potential Project-related effects on air quality, as outlined below, were identified based on a selection of measures and follow-up programs for other major transportation developments undertaken by the Ministry. Input from regulators and other stakeholders for major improvement projects such as the Sea to Sky Highway, Port Mann/Highway 1, and the South Fraser Perimeter Road/Highway 17 have also been considered.

Air Quality and Dust Control Management Plan

As described in **Section 12.0 Management Plans**, a Construction Environmental Management Plan (CEMP) will be developed for works to be undertaken by the Ministry or its contractors. As a component to the CEMP, an Air Quality and Dust Control Management Plan will be developed, which will describe measures to control and minimize fugitive dust and other airborne emissions associated with construction equipment, demolition, and other decommissioning activities, and soil handling. Specifically, this plan will describe the following:

- Regulatory permits necessary for the operation of construction equipment or machinery capable of producing point-source emissions
- Procedures to be implemented for the application of dust suppressants to construction areas and stockpiles to control fugitive dust and other airborne emissions
- Prohibitions regarding chemical suppressants and the burning of refuse or other material, unless otherwise authorized in an air discharge permit

The following industry standards and best management practices may be included in the Air Quality and Dust Control Management Plan for the mitigation of potential changes in local air quality resulting from Project construction:

- Operate equipment at optimum-rated loads
- Follow routine equipment maintenance procedures
- Turn off equipment, if practical, when not in use
- Maintain all heavy-duty diesel on-road vehicles (i.e., licensed vehicles, such as dump trucks) in good working order while operating on the Project site
- Install diesel PM filters in construction equipment and vehicles
- Use ultra-low sulphur diesel fuel (maximum 15-ppm sulphur content), and catalyzed particulate traps or a diesel oxidation catalyst in all heavy-duty diesel on-road vehicles and other diesel construction equipment
- To the extent possible, minimize double-handling of fill materials to limit hours that machines are operating
- Minimize generation of road dust during construction by:
 - minimizing the time unpaved surfaces are exposed
 - cleaning roadways regularly and removing debris
 - providing tire wash facilities to minimize tracking of mud and generation of road dust onto paved roads
 - watering unpaved hauling and unpacked surfaces as frequently as needed
 - covering dump truck loads that are hauling fine-grained materials, particularly to and from off-site locations

Best management practices to be followed during Project construction will be designed in accordance with appropriate regulations and the Air Quality and Dust Control Plan will be developed and submitted to relevant agencies for review and comment prior to construction.

Air Quality and Dust Control Plans and BMPs as identified above were developed and implemented during construction of previous major transportation infrastructure projects such as Port Mann/Highway 1, South Fraser Perimeter Road/Highway 17, and Sea to Sky Highway. Air quality monitoring and management conducted during the construction phase of these projects ensured that applicable air quality objectives were achieved.

Measures for Vehicle Emissions during Project Operations

Most pollutants from vehicle emissions are predicted decline in the 2031 scenario with the Project and the 2031 scenario without the Project due to fleet turnover. The 2031 scenario with the Project shows a greater decline in most pollutants from vehicle emissions due to reduced idling and more fuel efficient travel speeds. Hence, the implementation of mitigation measures for vehicle emissions is not considered necessary.

To address potential minimal incremental air quality effects during Project operation, the following mitigation measures are proposed:

- Design and manage the Project to ensure optimum traffic flow conditions
- Include options for increasing mode split by extending transit and HOV lanes, improving transit along the Project alignment with integrated transit stops and transit-only ramps at Bridgeport Road and Highway 17A, and providing multi-use pathways on the bridge and other locations for pedestrians and cyclists with connections to the regional cycling network.

Measures for Road Dust during Project Operations

Once operational, the new bridge and upgraded Highway 99 could result in an increase in road dust because of the projected growth in traffic VkmT. Road dust during Project operation will be managed at an appropriate frequency by cleaning the road where dirt, debris, sand, and gravel have accumulated, in accordance with Ministry requirements for highway maintenance (B.C. MOTI 2010).

4.9.5 Residual Effects

Implementing the mitigation measures described in **Section 4.9.4.2** will minimize potential Project-related changes on air quality during construction, although temporary, minor residual effects will be incurred.

Potential Project-related residual effects on air quality are characterized with respect to the direction, magnitude, extent, duration, frequency, reversibility, and likelihood of each anticipated residual effect. Definitions for ratings applied to residual effects criteria, developed with specific reference to air quality are presented in **Table 4.9-10**. A summary of criteria ratings for the potential residual effect is provided in **Table 4.9-11**. Context of the residual effects assessment (i.e., sensitivity/resilience to potential Project-related effects), based on existing conditions, is also provided.

Table 4.9-10 Criteria Used to Characterize Residual Effects on Air Quality

| Criteria | Description | Definition of Rating | |
|-----------|--|----------------------|---|
| Direction | Overall nature of the residual effect | Adverse | Negative effect as a result of the Project. |
| | | Positive | Beneficial effect as a result of the Project. |
| | | Neutral | Neutral effect as a result of the Project. |
| Magnitude | Intensity of the effect relative to natural or baseline conditions | Negligible | No measurable change |
| | | Low | A measurable change within the range of natural variability, but not affecting air quality |
| | | Moderate | A measurable change outside the range of natural variability, but not posing a risk to receptors |
| | | High | A measurable change outside the range of natural variability and may have long-term effect on receptors |
| Extent | Geographic extent / distribution of the residual effect | Site | Effect is restricted to the immediate Project alignment. |
| | | Local | Effect is restricted to the LAA. |
| | | Regional | Effect is restricted to the RAA. |
| Duration | Length of time over which the residual effect is expected to persist | Short term | Effect occurs for up to less than 3 months |
| | | Moderate term | Effect limited to construction period |
| | | Long term | Effects persist beyond construction |

| Criteria | Description | Definition of Rating | |
|---------------|---|----------------------|--|
| Frequency | Nature of the occurrence of the residual effect (e.g., how often the stressor affects the IC) | Occasional | Effect occurs intermittently during Project construction. |
| | | Frequent | Effect occurs up to 5 days a week during Project construction. |
| | | Continuous | Effect occurs more than 5 days a week during Project construction. |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after the disturbance has ceased (or after a period of time after the disturbance has ceased) | Reversible | Baseline conditions will be naturally restored after disturbance has ceased. |
| | | Irreversible | Baseline conditions will not be naturally restored after disturbance has ceased. |
| | | Change | Effect may fluctuate between positive and adverse for the duration of the disturbance. |
| Likelihood | Likelihood that the residual effect may occur | Low | Likelihood of residual effect is less than 25%. |
| | | Moderate | Likelihood of residual effect is between 25% and 75%. |
| | | High | Likelihood of residual effect is greater than 75%. |

4.9.5.1 Construction

The types of air emissions expected during Project construction (e.g., from construction equipment) are different than those associated with highway traffic, and Project construction is expected to have some influence on local air quality. **Table 4.9-11** presents a summary of the criteria ratings for potential effects on air quality during construction activities.

Context: The Project is located in an urban setting, where emissions from traffic and industries play a predominant role in influencing local and regional air quality. Air quality monitoring undertaken by the Ministry during construction of comparable transportation infrastructure projects in the past, including Sea to Sky Highway, Port Mann/Highway 1, and South Fraser Perimeter Road/Highway 17, demonstrate that, with standard best management practices and proven mitigation strategies discussed in **Section 4.9.4.2**, construction-related emissions can be considered immaterial in comparison to traffic, industry, and other emissions that contribute to ambient air quality in and around the Project area. Sensitivity of ambient air quality to emissions from Project-related construction is, therefore, considered to be low.

Table 4.9-11 Criteria Ratings: Change in Air Quality During Construction Activities

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|--------------------------|---|
| Direction | Neutral | Emissions during construction will be managed using best management practices. |
| Magnitude | Low | Change will be within the range of natural variability and is not expected to adversely affect air quality. |
| Extent | Site | Spatial extent will be restricted to the area of disturbance. |
| Duration | Short term | Effect will occur only during construction. |
| Frequency | Occasional to continuous | Frequency of effect will vary dependent on nature and location of specific construction activities. |
| Reversibility | Reversible | Potential effects cease upon completion of construction. |
| Likelihood | High | Construction-related emissions are expected to have some influence on local air quality. |

Project construction will be undertaken using standard practices and equipment employed on comparable transportation infrastructure projects in the Lower Mainland by the Ministry, with the implementation of best practices and mitigation measures. Because potential incremental changes to air quality associated with highway construction are well-understood and can be addressed through the application of mitigation measures that have been demonstrated to be effective on comparable projects, any potential adverse residual effects of Project-related construction on air quality are expected to be low in magnitude, and confined to active construction areas. Such effects will be temporary, of short-duration, and fully reversible.

4.9.5.2 Operation

Once operational, the Project is expected to result in an improvement in air quality, compared to existing conditions and future conditions without the Project, even with an increase in traffic. Based on the results of air quality modelling, without the Project, maximum concentrations of carbon monoxide, nitrogen dioxide, benzene, and benzo(a)pyrene associated with Highway 99 traffic in the Project alignment are predicted to exceed the most stringent AAQOs in 2031. With the Project, no AAQO exceedances are predicted in 2031, except benzo(a)pyrene and the maximum 1-hour NO₂ concentration, both of which exhibit existing concentrations that are higher than those predicted with Project improvements. Therefore no post-construction Project-related adverse residual effects are expected.

4.9.6 Cumulative Effects

The combination of Project-related changes, and changes from other certain and reasonably foreseeable projects and activities, as listed in **Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**, comprise the total cumulative changes in air quality. This includes TransLink's proposed Pattullo Bridge replacement, with a planned construction period between 2019 and 2023, which overlaps temporally with the Project; however, given the distance between the two projects, no spatial overlap of potential construction-related air quality effects are expected.

A brief overview of the predicted effects of the Project on regional air quality in 2031 is presented below. A more complete discussion is presented in **Section 6** of the technical volume, **Air Quality Study (Section 16.5)**. Greenhouse gas emissions have been identified as important to stakeholders, Aboriginal Groups, and the public. A brief discussion on Project-related change in traffic emissions in the context of regional emissions and greenhouse gas (GHG) considerations is presented below.

Regional Emissions

TransLink is currently developing a Regional Transportation Model (RTM) that will enable estimation on impacts on a regional basis. While the RTM is in early development stages, initial results indicate that implementation of the Project as proposed will result small decreases in total regional vehicle-kilometers traveled, as well as in total vehicle-hours of travel time. These results indicate that emissions are forecast to decline on a regional basis, as well as within the local assessment area, as a result of the Project.

Project-related air emissions as well as future changes in regional emissions that may occur as a result of other transportation projects or changes in regulatory policies and programs were considered in assessing potential regional air quality effects of the Project. The results of this assessment in terms of total annual vehicle emissions of key pollutants in the lower Fraser Valley, and proportion of the total emissions associated with the Project are shown in **Table 34** of the technical volume, ***Air Quality Study (Section 16.5)***. In general, total estimated emissions of CACs from traffic in the 2031 scenario with the Project are between one and five per cent of the total vehicle emissions in the lower Fraser Valley.

An overview of regional air quality in 2031 with and without the Project in terms of maximum overall pollutant concentrations (i.e., predicted maximum Project-related emission concentrations plus background concentrations) is shown in **Table 4.9-12**. Values in bold indicate an exceedance of the most stringent AAQOs. Overall ambient concentrations of all pollutants in the region are predicted to be lower in the 2031 scenario with the Project when compared to the 2031 scenario without the Project and 2011 baseline. For the 2031 scenario with the Project, NO₂ (100% conversion), PM₁₀, PM_{2.5} and benzene are the only pollutants that show some exceedance over the most stringent AAQOs, as they do in 2011. When the Ambient Ratio Method is applied to the predicted NO_x concentrations, there are no exceedances of the 1-hour objective in 2031 with the Project.

Table 4.9-12 Predicted Regional Air Quality with and without the Project in 2031

| Pollutant | Averaging Period | Background Concentration ($\mu\text{g}/\text{m}^3$) | Overall Concentration in 2031 without Project ($\mu\text{g}/\text{m}^3$) | Overall Concentration in 2031 with Project ($\mu\text{g}/\text{m}^3$) | Most Stringent AAQO ($\mu\text{g}/\text{m}^3$) |
|-------------------------|------------------|---|--|---|--|
| CO | 1-hour | 1271 | 18,771.5 | 12,248.6 | 14,300 |
| | 8-hour | 1,116 | 5,586.6 | 3,555.8 | 5,500 |
| NO ₂ (ARM) | 1-hour | - | 105.9 | 96.3 | 188 |
| | Annual | 25 | 70.4 | 43.6 | 40 |
| SO ₂ | 1-hour | 10 | 39.9 | 18.3 | 450 |
| | 24-hour | 7 | 10.3 | 8.0 | 125 |
| | Annual | 2 | 3.0 | 2.3 | 25 |
| Total PM ₁₀ | 24-hour | 29 | 97.2 | 62.2 | 50 |
| | Annual | 13 | 34.1 | 22.2 | 20 |
| Total PM _{2.5} | 24-hour | 15 | 35.6 | 24.6 | 25 |
| | Annual | 4 | 10.3 | 6.7 | 8 |
| Benzene | 24-hour | 2 | 6.0 | 3.7 | 2.3 |
| | Annual | 1 | 2.2 | 1.5 | 0.45 |
| 1,3-butadiene | 24-hour | 0.4 | 0.8 | 0.6 | 10 |
| | Annual | 0.1 | 0.2 | 0.1 | 2 |

Greenhouse Gas Emission Considerations

Greenhouse gases (GHGs) are contributors to the radiative warming effect of the environment that results in global climate change. The major GHGs include CO₂, CH₄ and N₂O, which are emitted from fuel combustion as well as other anthropogenic and natural sources. In addition, the warming effects of black carbon may be significant on a local geographic basis, especially on a shorter time scale².

² Black carbon is present in particulate matter generated by fuel combustion processes, and absorbs solar radiation at all wavelengths. Given its shorter residence time in the atmosphere than GHGs, the use of the 100-year global warming potential (GWP) factors to determine CO₂ equivalency may not be appropriate. Hence, published 20-year GWPs for GHGs and black carbon (Solomon et al. 2007, Minjares et al. 2014) were used to estimate the magnitude of the climate change effects of Project-related black carbon emission and its potential contribution to local climate change. Other components such as sulphates, nitrates, and organic carbon (OC) present in particulate matter generally reflect light and have a cooling effect that may partially offset the warming effect of black carbon.

In the context of GHG emissions generated in the Project alignment today, current congestion results in substantially more GHG emissions (CO₂e) than would occur without such congestion. As illustrated in **Table 4.9-13**, the elimination of the one million vehicle delay hours that occur annually due to existing congestion would result in a reduction in CO₂e emissions by existing traffic of more than 13,000 tonnes.

Table 4.9-13 Existing 2011 CO₂e Emissions, with and without Congestion

| | 2011 Existing Roads | | |
|--|--|--|--------------------------------------|
| | Existing Emissions with Congestion (tonnes/yr) | Emissions without Congestion (tonnes/yr) | Change from Existing with Congestion |
| CO ₂ e (20-year) ³ | 163,157 | 149,774 | -13,383 (-8.2%) |

Considering future GHG emissions in the Project alignment, **Table 4.9-14** summarizes the comparison of emissions for the 2031 scenarios, with and without the Project. For the scenario without the Project, emission estimates have taken into account the effects of traffic congestion during rush hours on a weekday. Emissions for the existing scenario (2011) are also presented to show the temporal reductions in GHG and black carbon emissions over time.

Table 4.9-14 Forecast 2031 CO₂e Emissions, with and without Project (untolled)

| Pollutant | 2011 Existing Roads Emissions (tonnes/yr) | 2031 Emissions (tonnes/yr) | | Change from Without Project Scenario in 2031 |
|------------------------------|---|----------------------------|--------------|--|
| | | Without Project | With Project | |
| CO ₂ | 146,939 | 129,338 | 121,493 | -7,845 |
| CH ₄ | 12.2 | 15.0 | 15.1 | 0.1 |
| N ₂ O | 8.0 | 3.5 | 3.5 | 0 |
| Black carbon | 4.1 | 1.1 | 1.2 | 0.1 |
| CO ₂ e (20-year) | 163,157 | 135,002 | 127,336 | -7,666 (-5.7%) |
| CO ₂ e (100-year) | 153,287 | 131,753 | 123,973 | -7,780 (-5.9%) |

Note: Because the new bridge will be tolled, CO₂e reductions with the Project are projected to be greater than those noted above.

³ CO₂e (equivalent) emissions are based on the following respective weighting factors for 20-year and 100-year global warming potential per tonne of emission: CO₂ (1 and 1), CH₄ (72 and 25), N₂O (289 and 298), and black carbon (3,200 and 900).

As illustrated in **Table 4.9-14**, a substantial decrease in GHG emissions (CO₂e) on the Highway 99 corridor is forecast between 2011 and 2031, both with and without the Project,⁴ as newer engine technologies provide significant reductions in overall CO₂e emission levels.

Even if the Project did not include tolling, CO₂e emissions in 2031 are forecast to decrease by 7,700 to 7,800 tonnes (5.7% to 5.9%) relative to without the Project. This net GHG reduction reflects savings due to congestion relief associated with Project improvements, which more than outweigh emissions associated with higher traffic volumes in an untolled scenario.

The 7,700 to 7,800 tonne annual reduction can be characterized as a “worst case” scenario, since it is based on the Highway 99 corridor being untolled. As the Project will be tolled, GHG reductions are projected to be greater due to the dampening effect on traffic volumes.

4.9.7 Follow-up Strategy

Air Quality and Dust Control Plans and BMPs as identified in **Section 4.9.4.2** will be developed and implemented to ensure potential construction-related effects on air quality are managed. Regular monitoring and analysis will be conducted during construction to confirm applicable air quality objectives are achieved.

As no Project-related effects are predicted beyond the construction phase, no post-construction follow-up strategy is proposed.

⁴ The only forecast increase in emissions, for CH₄, is due to the combination of increasing traffic and increasing frequency of diesel-engine vehicles, which are projected to outweigh the decrease in CH₄ emission rates for similar-engine vehicles. This CH₄ emissions trend is also observed in Metro Vancouver's 2010 emissions inventory and forecast (Metro Vancouver 2013).

"N/A" indicates that no Project works and/or activities are applicable to the category

4.10 Atmospheric Noise Assessment Highlights:

- Ambient noise levels in the Project area are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Trains, aircraft, marine, and agricultural activities also contribute to ambient noise in and around the Project area.
- Construction-related noise can be addressed by applying mitigation and best practices, including the following, that have proven to be effective on other recent transportation infrastructure projects in the Lower Mainland:
 - Equipment and activity restrictions to minimize noise emissions
 - Noise monitoring program
 - Processes for community communication, engagement, and adaptive management.
- Appropriate mitigation measures will be implemented at select locations to address Project-related change in noise levels during operation.
- With the application of mitigation, ambient noise levels during operation are expected to be lower than current levels—on average by 4 dBA at residences and 1.5 dBA at schools and places of worship.
- Noise levels at parks adjacent to the Project, including Deas Island Regional Park, are expected to increase by varying degrees dependent on the distance from the highway, but will generally remain below levels that warrant mitigation consideration for residential and institutional use.
- No significant Project-related residual or cumulative effects on atmospheric noise are predicted post construction.

4.10 Atmospheric Noise

This section describes the existing conditions related to atmospheric noise and anticipated changes resulting from Project components and activities. Atmospheric noise is studied as an intermediate component (IC), and the information presented on predicted changes in atmospheric noise is used to support the assessment of potential effects of the Project on human health, terrestrial wildlife, and land use (**Section 4.8 Terrestrial Wildlife, Section 5.3 Land Use, and Section 7.1 Human Health**).

A technical volume, **Atmospheric Noise Study**, containing technical details on the methodology used to evaluate existing conditions and predict Project-related changes is included under **Section 16.6**.

4.10.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on atmospheric noise in terms of Project setting, and defines the spatial, temporal, administrative and technical assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

4.10.1.1 Assessment Context

Construction activities associated with the Project, including highway upgrades, reconfiguration of interchange ramps, construction of the new bridge, and decommissioning of the Tunnel, have the potential to temporarily alter atmospheric noise conditions in and around the Project alignment. Post construction, changes in traffic volumes, vehicle types, and travelling speeds resulting from the upgraded traffic corridor, and alignment changes of some highway components, specifically the introduction of the new bridge, may result in an alteration of the noise environment in the vicinity of the Project. Predicting the anticipated nature and magnitude of such changes is important for assessing Project-related effects on human health, wildlife, and land use, which have all been defined as valued components (VCs) in this environmental assessment. The decision to undertake an assessment of Project-related effects on atmospheric noise was also informed by feedback received through pre-Application consultation on the Project with government agencies, Aboriginal Groups, and the general public. Potential influence of the Project on atmospheric noise and consequent effects on human health, terrestrial wildlife, and land use was identified as an area of specific interest by Vancouver Coastal Health, Fraser Health, Metro Vancouver, local communities (City of Richmond, Corporation of Delta), and Aboriginal Groups. Metro Vancouver expressed an interest in potential Project-related effects on noise within Deas Island Regional Park, and Aboriginal Groups expressed an interest in potential effects of Project-related changes in atmospheric noise on wildlife. Potential influence of change in noise conditions on quality of experience in the context of traditional uses was also identified as an area of interest by Aboriginal Groups.

Additional information on the selection of VCs, and the link between atmospheric noise and the above VCs, is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**. The assessment of atmospheric noise follows the general methodology described in **Section 3.0 Assessment Methodology**.

In late 2013, the Ministry initiated field and desktop studies and modelling to support the environmental assessment of the Project. The studies had the following key objectives, and were designed to build on existing information and address known data gaps:

- Describe, through monitoring, existing noise environments at locations representative of noise-sensitive land uses that may be affected by the Project
- Assess potential effects of Project-related construction noise and ground-borne vibration (associated with pile-driving only) on noise-sensitive receptors
- Predict Project-related changes in operational (traffic) noise exposures at noise-sensitive receptors

- Identify appropriate mitigation measures and best practices to eliminate or minimize atmospheric noise increases at noise-sensitive receptors
- Estimate residual Project-related changes in noise conditions that may remain after application of appropriate mitigation
- Identify cumulative changes that may result from the interaction of Project-related residual changes and changes in noise conditions attributable to other certain or reasonably foreseeable projects or activities

The objectives identified above were addressed through the completion of studies outlined in **Table 4.10-1**. Technical details of these studies are provided in the technical volume, **Atmospheric Noise Study, Section 16.6**.

Table 4.10-1 Atmospheric Noise Studies

| Study Name | Study Description |
|---|--|
| Pre-Project Noise Monitoring | Continuous noise monitoring was conducted (for 24-hour, 48-hour, and shorter periods) at noise-sensitive receptor sites in the vicinity of the Project to establish existing ambient noise conditions. |
| Post-Project (2030) Traffic Noise Modelling | Post-Project (i.e., operation phase) traffic noise levels were predicted to 2030 using numerical modelling along the new bridge and approaches, and baseline adjustment method for the remainder of the highway alignment. |
| Project Construction Noise Forecasts | A generic approach was taken to estimate noise levels typically experienced during standard highway construction activities at various setback distances. Pile driving noise was estimated using numerical modelling. |

4.10.1.2 Methodology

The following methods and procedures have been used to assess the baseline and future (post-Project) operational atmospheric noise conditions as well as construction noise levels within the extent of the Project:

- Baseline (pre-Project) noise monitoring was conducted at noise sensitive locations as shown on **Figure 4.10-1**.
- CadnaA outdoor sound propagation software was used to model post-Project noise exposures at noise-sensitive locations in the vicinity of the new bridge and its approaches, where proposed changes in the vertical alignment of Highway 99 are substantial.
- The baseline adjustment method (BAM) was used to predict post-Project noise exposures at noise-sensitive locations along Project segments where proposed changes to the horizontal and vertical alignments of Highway 99 are negligible or minor.

- Locations (residential and others) at which mitigation consideration is warranted under the Ministry’s 2014 noise policy were identified based on measured pre-Project (baseline) and post-Project (predicted) noise levels.
- The CadnaA model developed to predict post-Project noise exposures was used to assess potential effectiveness of mitigation measures in the vicinity of the new bridge. Effectiveness of mitigation measures at the remaining locations were assessed using basic acoustic principles.
- Construction noise exposures at noise sensitive locations have been estimated through a generic construction noise procedure¹ appropriate for use in the assessment stages of projects when detailed construction equipment lists and schedules are not available

An overview of the methodology used, metrics obtained in noise monitoring, and relevant thresholds considered in assessing noise conditions is provided below. Methodology used to assess potential Project-related changes is discussed briefly in **Section 4.10.3.1**. Technical details on noise monitoring and assessment methodology are included in the technical volume, **Atmospheric Noise Study, Section 16.6**.

Monitoring to Establish Existing Conditions

To document and characterize the existing (pre-Project) noise environments in the study area, monitoring was conducted at representative residential and non-residential noise-sensitive locations shown on **Figure 4.10-1**. Selected receptors were discussed with relevant stakeholders during the pre-Application consultation on the Project to confirm their suitability.

Continuous monitoring at all sites was conducted between October 2 and November 22, 2013, and between April 7 and 9, 2014. Monitoring data collected in September 2013 from an adjacent project was used for two sites.

Monitoring was conducted using logging sound level meters compliant with ANSI S1.4 standards for type 1 precision sound level meters. Technical details on methods, including equipment, noise level histories obtained at monitoring sites, site photos and descriptions, and dominant sources of existing noise are presented in the technical volume, **Atmospheric Noise Study, Section 16.6**.

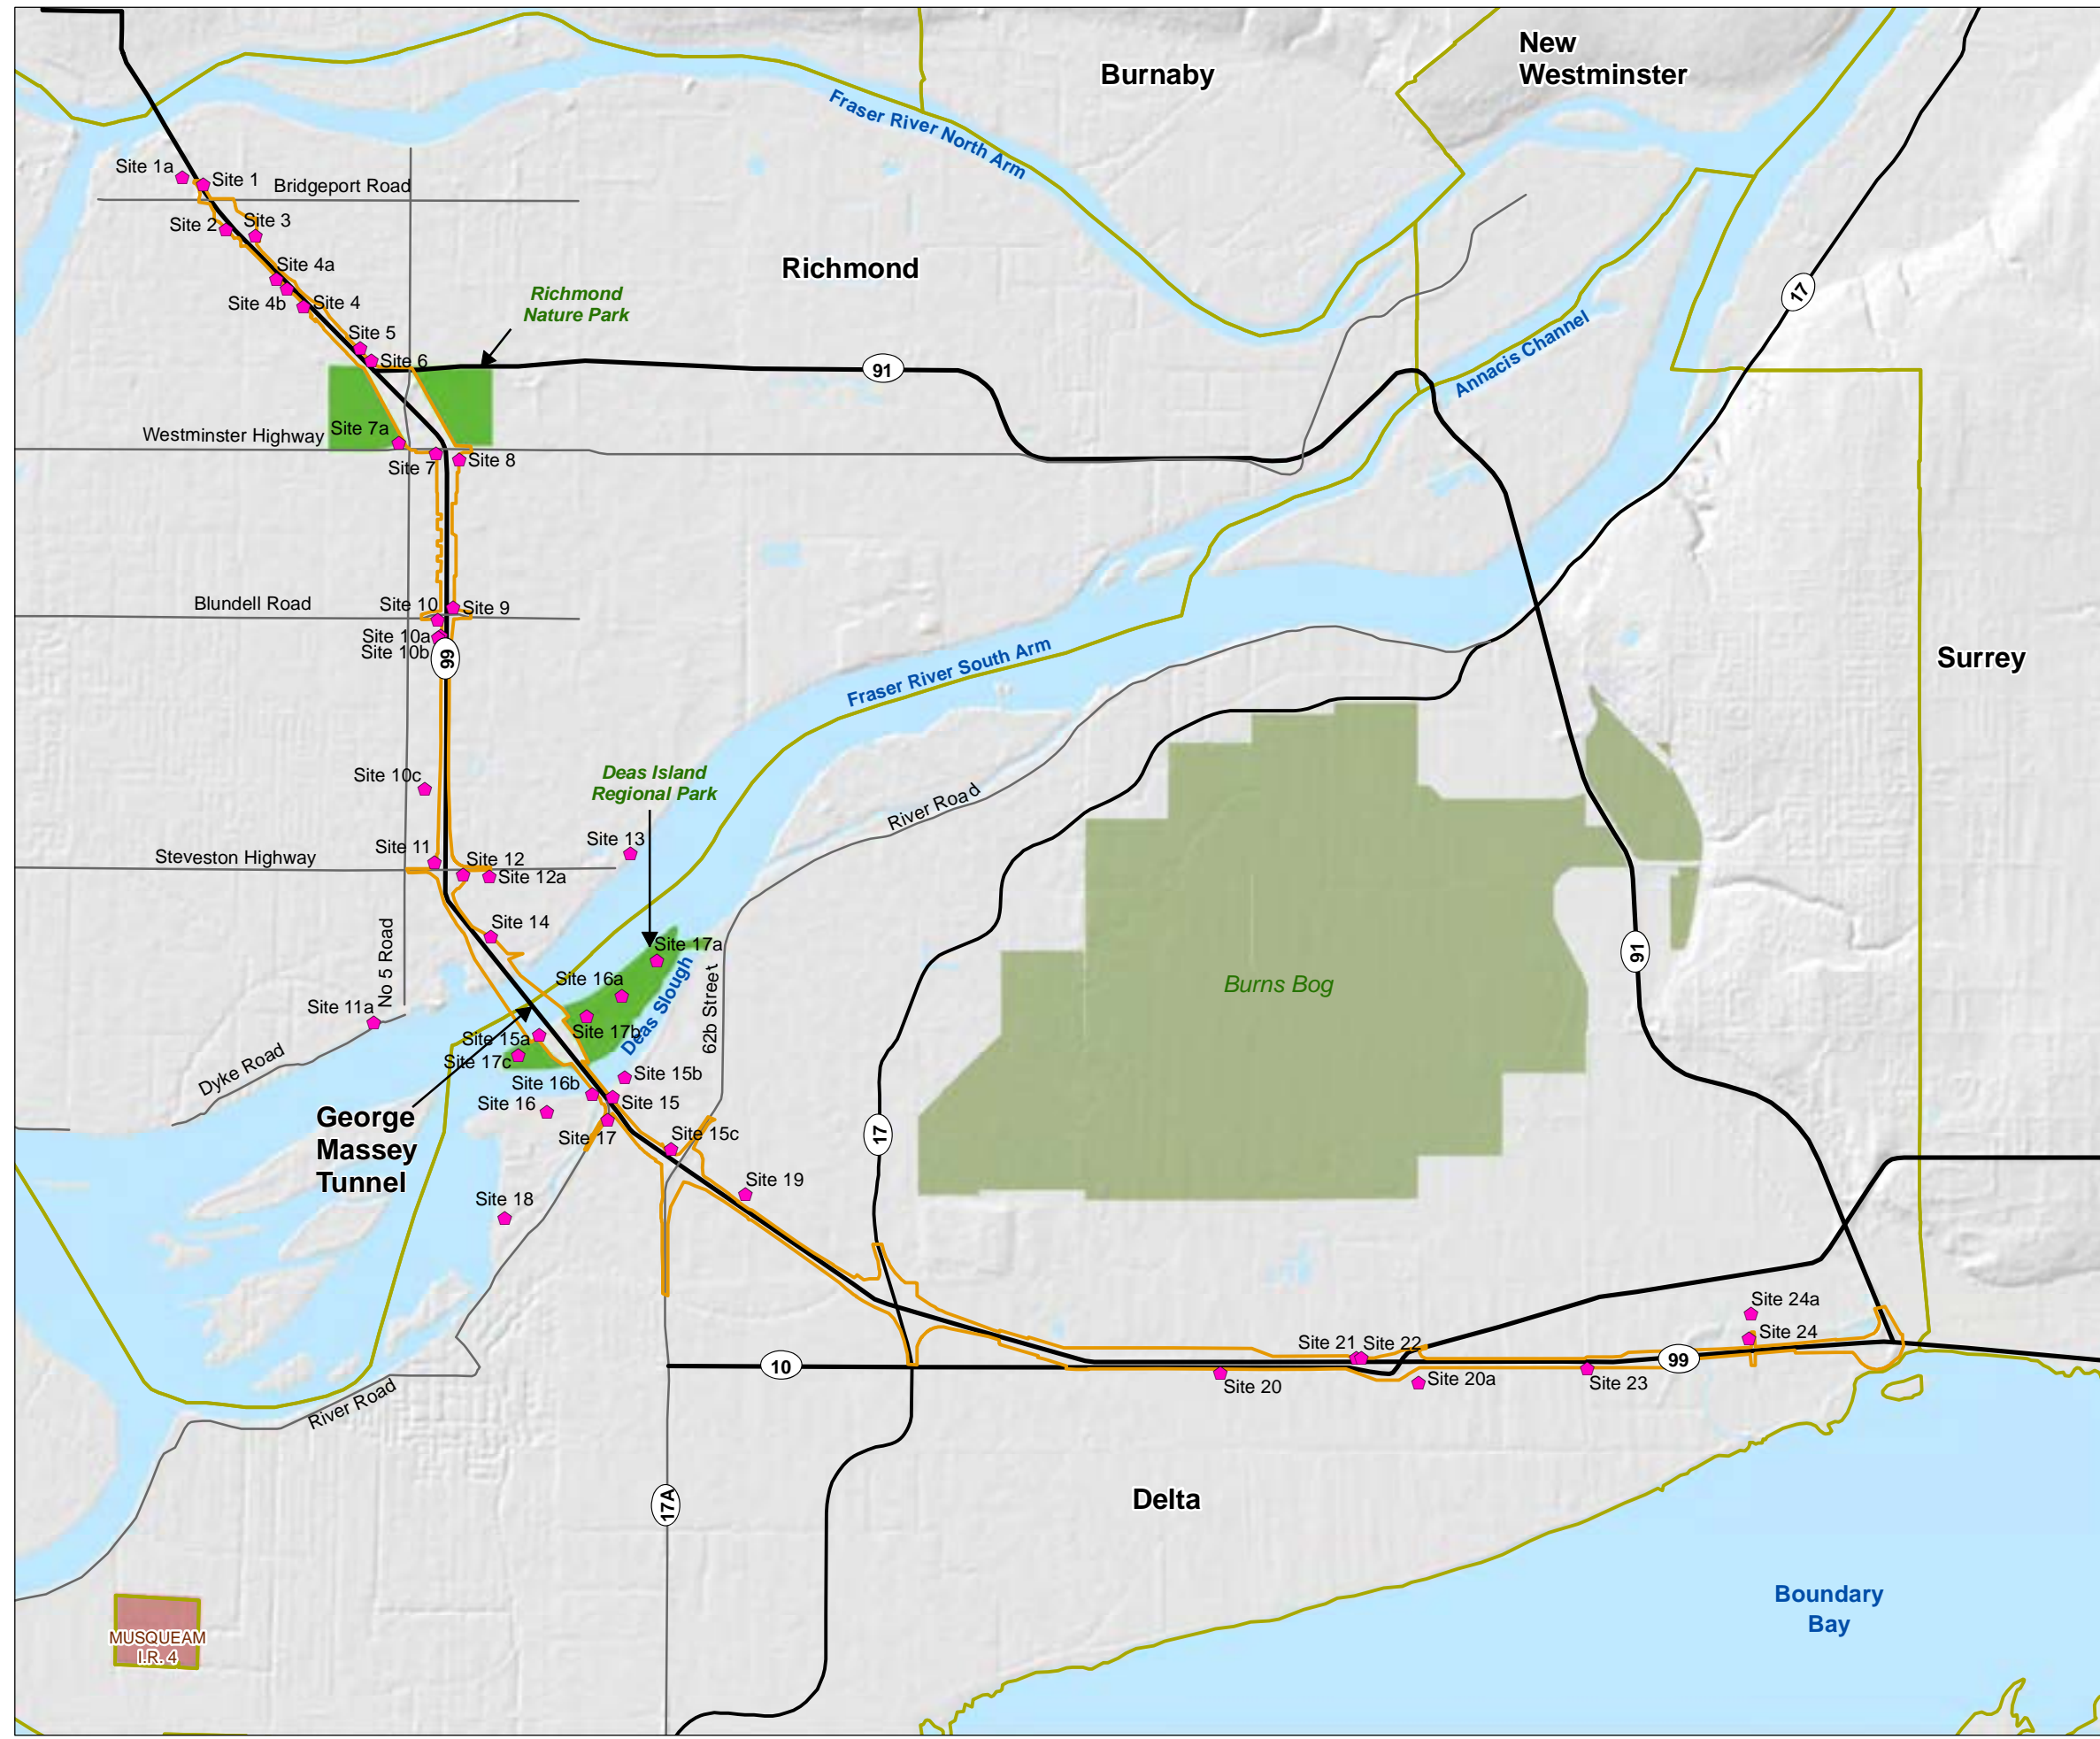

¹ This procedure has been used in previous applications for the Sea to Sky Highway Improvement, South Fraser Perimeter Road and Port Mann/Highway 1 projects.

Noise Metrics

The principal noise metric obtained for the Project, through monitoring, is the day-night average noise level (L_{dn}), which is the primary noise metric used in the Ministry's *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways* (Wakefield Acoustics Ltd. 2014), hereafter referred to as the Ministry's 2014 noise policy. Noise monitoring also provided the daytime average sound level (L_d), which is the equivalent sound level (L_{eq}) between 7 a.m. and 10 p.m., and the nighttime average sound level (L_n), which is the L_{eq} between 10 p.m. and 7 a.m. While these latter two noise metrics are not used directly in the Ministry's 2014 noise policy, they provide important information relevant to the human health effects assessment (**Section 7.1 Human Health**).

Relevant Community Noise Thresholds

The threshold beyond which noise has the potential to interfere with sleep is identified as L_n of 30 dBA indoors, which can be reached when outdoor noise levels are in the L_n 45 to 70 dBA range (WHO 1999). Thresholds beyond which noise has the potential to interfere with conversation are identified as L_d 55 dBA for conversations indoors, and L_d 45 dBA in classrooms. Depending on the nature and condition of the school façade, indoor levels of 45 dBA can be reached when outdoor noise levels are in the L_d 60 dBA to 75 dBA range.

4.10.1.3 Assessment Boundaries

The assessment boundaries for atmospheric noise are defined below.

Spatial Boundaries

The assessment area for atmospheric noise includes those areas in the vicinity of the Project where noise impacts are likely to occur. Boundaries of the assessment area were established based on the lateral distance beyond which daily-average noise levels from traffic related to the Project would not be expected to exceed what is considered acceptable for residential land uses. The metrics used to determine acceptability are based on those identified by the U.S. EPA (1974) and the Canada Mortgage and Housing Corporation (CMHC) (1981).

The lateral distance within which Project-related traffic could affect atmospheric noise will depend on the volume, average speed, and heavy truck component of the future traffic streams on Highway 99. This distance will also depend on the elevation of the traffic above the ground and the nature of the ground surface between the highway and the noise-sensitive receptors. Where sound travels close to the surface of the earth and, in particular, where the intervening surface is acoustically absorptive, or soft (i.e., grass, farmland, or wooded areas), the rate at which sound levels are attenuated with distance is relatively high. Where the sound source is elevated well above the ground and, in particular, where the intervening surface is acoustically reflective, or hard (i.e., water, pavement, or hard-packed earth/gravel), the rate of attenuation of sound levels with distance is generally lower.

For these reasons, for the majority of the study area within which Highway 99 is close to natural ground level and largely bordered by agricultural or undeveloped lands, the study area width extends 500 m from either side of the Project footprint. This width is sufficient to capture the following:

- Residences north of the Fraser River on both sides of No. 5 Road, which parallels Highway 99 to the west, and Sidaway Road, which parallels Highway 99 to the east.
- Residences south of the Fraser River along 64th, 72nd, 80th, 88th, 96th Streets, Burns Drive, and Ladner Trunk Road.

In the vicinity of the new bridge, where Highway 99 traffic will be elevated well above natural ground level, and where much of the surrounding surfaces are water, the study area extends approximately 1,600 m from either side of the Project footprint, since the rate of decrease in sound levels over these acoustically reflective surfaces is lower. This distance is sufficient to capture the following:

- Condominium buildings located along Riverport Way in Richmond on the north bank of the Fraser River to the east of Highway 99 and the new bridge.
- Townhouses along Regatta Way, Delta, to the west of Highway 99.
- Residences and parks along Dyke Road and residences along Rice Mill Road in Richmond.
- Residences along River Road and Admiral Way in Delta.

Based on the above considerations, select noise-sensitive locations along the Project alignment as shown on **Figure 4.10-1** were selected as ambient noise monitoring stations to support the assessment of Project-related changes in atmospheric noise levels.

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects were established based on the potential for each phase of the Project to interact with and have an effect on atmospheric noise. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, both the construction and operational phases of the Project include components and activities that could interact with and affect atmospheric noise conditions along the Project alignment; therefore, the following temporal boundaries were defined for atmospheric noise assessment:

- Existing conditions
- Project construction, which includes Tunnel decommissioning
- Project operation, including maintenance

Temporal characteristics (timing) of the Project construction phase (including decommissioning of temporary construction-related facilities and the Tunnel), and operational phases are defined in **Section 1.1.3 Project Phases and Schedule**.

Temporal boundaries for the atmospheric noise study were defined as extending from initiation of Project construction to 10 years after completion of the Project construction, in accordance with the Ministry's 2014 noise policy. The anticipated Project completion date of 2022 puts the 10-year post-completion horizon year at 2032; however, 2030, the year for which future traffic

volume projections were available, was used as the horizon year for this assessment². This temporal period encompasses existing conditions, and the Project construction and operations phases.

Administrative Boundaries

No administrative boundaries, (i.e. political, economic, or social constraints on the collection or analysis of data), relevant to the assessment of atmospheric noise, were identified.

Technical Boundaries

The level of accuracy and precision of the baseline noise measurements is ± 0.5 dBA for the instrumentation itself. Day-to-day variations in traffic volumes on major highways are generally not large enough to cause variations in daily average noise levels of more than ± 0.5 dBA.

Traffic volume modelling, which forms the basis of future traffic noise-level predictions, has a certain margin of error; however, given the relatively weak relationship between traffic volumes and average noise levels (3 dBA per doubling of volume), the influence of this margin on predicted noise levels is considered negligible.

Prediction of future (2030) traffic noise levels using the BAM method in situations where the highway alignment is not changing substantially is typically accurate to within approximately ± 0.5 dBA while predictions made using a TNM/CadnaA model are typically accurate to within ± 1.0 to 2.0 dBA when geometries are not overly complex and setback distances are not too large. However, it has to be noted that the TNM/CadnaA modelling approach considers meteorological conditions favourable for sound propagation (i.e. noise receiver downwind of noise source), which results in a somewhat conservative estimation of noise levels in situations involving sound propagation over soft ground.

4.10.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data, and describes the existing conditions of the noise environment within the assessment areas. An overview of the regulatory context as relevant to the Project is also provided.

² The difference in noise levels due to traffic growth from one year to the next is negligible. Should Project completion occur within a few years of 2022, the difference in forecasted noise levels in between is considered to be minor and within the acceptable margin of uncertainty for the operational noise impact assessment.

4.10.2.1 Regulatory Context

Community noise impacts associated with provincial highway projects are addressed in the Ministry's 2014 noise policy. Under this policy, noise effects are assessed at noise sensitive receptors such as residences, hospitals, educational facilities, places of worship, libraries, museums, and passive recreational facilities (parks). Mitigation measures, including Project design considerations, aim to promote public health and welfare and avoid situations where noise levels are inconsistent with a healthy residential environment, are intrusive and disruptive to the communities, and compromise the intended functioning of public facilities and noise-sensitive outdoor spaces. Typically, mitigation consideration is warranted when certain noise thresholds are exceeded.

There are currently no published Canadian guidelines, noise thresholds, or standards appropriate for the assessment of noise effects. Construction contractors are typically required to meet construction noise requirements of the jurisdictions where construction is taking place. Health Canada refers to a variety of internationally recognized standards for acoustics, such as the United States Environmental Protection Agency's (U.S. EPA) Information on Levels of Environmental Noise Requisite to Protect Public Health and Welfare with an Adequate Margin of Safety (U.S. EPA 1974, Health Canada 2010).

4.10.2.2 Factors Influencing the Existing Noise Environment

The existing noise environment along Highway 99 between Bridgeport Road and the Highway 91 interchange in Delta is controlled primarily by traffic on the highway and connecting roadways (i.e., Bridgeport Road, Westminster Highway, Steveston Highway, River Road, and Highways 17A, 17, 10, and 91). Other sources contributing to the noise environment, but to a lesser degree, include local traffic and activities, trains, aircraft, marine, and agriculture-related activities.

Changes in the noise environment in the vicinity of the Project in recent decades have largely been due to traffic volume growth on Highway 99 and, to a lesser degree, on connecting roadways.

Opening of the South Fraser Parameter Road (Highway 17) and associated interchange with Highway 99 in December 2013 resulted in some reduction in traffic (including heavy trucks) along Highway 17A south of Highway 99, and River Road north of Highway 99 (B.C. MOTI 2014). A comparison of Ministry traffic data collected near the south Tunnel portal before and after the opening of Highway 17 (i.e. October 2013 versus February and April 2014) shows that, after a brief period of adjustment following the opening of the new highway, traffic on Highway

99 through the Tunnel returned to volumes comparable to pre-Highway 17 numbers. This suggests that traffic volume changes associated with the opening of Highway 17 are not likely to have measurably altered the noise environment for most noise-sensitive receptors along the Project alignment. An exception is the Riverport Way condominium development on the Fraser River north shore, approximately 1,600 m east of Highway 99. Before Highway 17 was in operation, the noise environment was dominated by River Road traffic, south of the river. Ministry data show that total daily average traffic volumes on River Road decreased by about 30% with the opening of Highway 17, which suggests a consequent decrease in noise levels at Riverport Way condominium development.

4.10.2.3 Range of Existing Noise Levels along the Project Alignment

Existing noise levels at the select sensitive receptors are presented in **Table 4.10-5**. Existing noise levels range between 51.5 dBA and 75 dBA L_{dn} at residential receptors, and between 61.7 dBA and 71.8 dBA L_d at places of worship and schools in the vicinity of the Project. Existing noise levels in passive parks range from approximately 46 dBA L_d in Deas Island Regional Park to 58.0 dBA L_d near the south end of Richmond Nature Park.

4.10.2.4 Highway 99 Traffic Noise in the Study Area

Based on the results of monitoring, existing noise levels in the study area are generally controlled by Highway 99 traffic, with the following exceptions:

- Near Highway 99 and Westminster Highway in Richmond, there are secondary noise contributions from Westminster Highway traffic.
- The eastern end of the parking lot and trail system in Richmond Nature Park is 300 m from Highway 99, but only 60 m from Westminster Highway and 100 m from No. 5 Road. As such noise exposures are controlled by traffic on these two routes rather than by Highway 99 traffic.
- At Site 13 (Figure 4.10-1), situated at Riverport Condominiums on the Fraser River north bank, noise exposures were measured in autumn 2013 (i.e., prior to opening of Highway 17), and were found to be dominated by River Road traffic.
- Residence on Rice Mill Road in Richmond receives noise contributions from industrial and marine sources, particularly at night.
- Noise levels at residence on Ferry Road in Delta are controlled by local traffic and activities.
- At the municipal park along Dyke Road in Richmond, daytime noise levels are slightly influenced by Highway 99 traffic.

- Noise levels at Richmond Country Farms are influenced by traffic on the northbound off-ramp from Highway 99 to Steveston Highway.
- At the eastern end of Deas Island Regional Park, daytime noise levels were measured in November 2013 (i.e., prior to opening of Highway 17) and were found to be dominated by River Road traffic.
- Noise levels at two residences on 112th Street in Surrey near the southern limit of the project are dominated by railway activities rather than Highway 99 traffic.

Residences along No. 5 Road and Sidaway Road, between Westminster and Steveston Highway, are located approximately 400 m from Highway 99 over acoustically soft ground. Consequently, existing noise levels due to Highway 99 traffic at these residences are estimated to be below the threshold for noise concerns in residential areas. Residences on No. 5 Road are typically exposed to higher noise levels from local No. 5 Road traffic (estimated to be approximately 63 dBA based on 2006 traffic information; City of Richmond 2014) than from Highway 99. Highway 99 traffic noise levels at residences on Sidaway Road are anticipated to be similar to those expected at No. 5 Road residences. Influence of local traffic on noise levels at Sidaway Road residences are expected to be relatively low.

4.10.2.5 Future Conditions without the Project

To provide context for understanding potential Project-related changes, future (2030) noise conditions without the Project were estimated based on monitoring results and supporting information. Year 2030 was used as the reference year in predicting future noise conditions to make effective use of the vehicle fleet forecasts set out by Metro Vancouver and the Regional Transportation Model. Future noise levels are generally expected to be somewhat higher than existing levels due to gradual growth in traffic volumes.

As discussed in **Section 5.1 Traffic**, by 2030, growth in Highway 99 traffic volumes without the Project, expressed as annual average daily traffic (AADT), is expected to be in the range of 20% over the northern portion of the Project alignment (north of Highway 17A interchange) to 30% over the southern portion of the Project alignment (south of Highway 17A interchange). Without the Project, heavy truck mixes on Highway 99 are expected to increase from approximately 3.5% to 5% in 2013 to 5% to 11% in 2030.

Influence of this projected growth in total traffic volumes and truck mixes between 2013 and 2030 on noise levels (L_{dn}) are expected to be increases of approximately 2 dBA over the northern portion of the Project alignment, and between 2.2 and 3.2 dBA over the southern portion.

4.10.3 Potential Effects

4.10.3.1 Assessment Methods

Project-related changes in atmospheric noise were assessed using the following methods and procedures:

- The baseline adjustment method (BAM) was used to predict post-Project noise exposures at noise-sensitive locations where proposed alignment changes are minor (e.g., lane additions, on- or off-ramp alignment adjustments, and traffic volume and posted speed changes)
- Traffic noise model (TNM) within the outdoor sound propagation software, CadnaA, was used to predict post-Project (i.e., operation phase) noise exposures at noise-sensitive locations where proposed alignment changes are substantial (e.g., construction of new bridge and approaches)
- Comparison of baseline and predicted post-Project noise levels to identify locations where mitigation consideration is warranted
- Assessment of mitigation effectiveness in the vicinity of the new bridge using the TNM/CadnaA model, and at locations with proposed minor alignment changes using fundamental acoustic principles.

As discussed in **Section 5.1.2.4**, average annual daily traffic volumes (AADT) for 2030 were assessed using TransLink’s RTM for two scenarios– with the new bridge in place and no tolls being applied (TL-RTM Untolled), and with a new tolled bridge in place (TL-RTM Tolled). Given the variability in the forecasting, and to ensure a conservative assessment for EA purposes, the upper range of forecast values (TL-RTM untolled, 2030 With the Project) were used as it represents the highest potential volume of traffic.

Further detail on the TNM/CadnaA noise model, and how the BAM was used in predicting Project-related changes in noise conditions is provided in **Section 16.6 Atmospheric Noise Study Technical Volume**.

A generic highway construction noise model was used to estimate anticipated construction-related noise levels.

4.10.3.2 Project Interactions

An overview of potential interactions between Project activities and atmospheric noise during the construction and operation of the Project is provided in **Appendix A**. A preliminary evaluation of the potential effects of Project interactions on atmospheric noise, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Temporary noise generated during Project construction, and change in traffic conditions along the Project corridor post-construction, are expected to result in changes in ambient noise conditions within the study area. Less frequent, temporary changes in noise may be experienced during maintenance activities after the Project is operational, depending on the activity required.

As discussed in **Section 4.10.1.1**, potential influence of the Project on atmospheric noise and consequent effects on human health, terrestrial wildlife, and land use was identified as an area of specific interest by Aboriginal Groups, the public, government agencies (in particular Vancouver Coastal Health, Fraser Health, and Metro Vancouver), and local communities (City of Richmond, Corporation of Delta). Project-related changes in atmospheric noise are discussed in this section and mitigation measures proposed for addressing adverse effects are discussed in **Section 4.10.4** below. The potential health effects of change in exposure to atmospheric noise are discussed in **Section 7.1 Human Health**. Changes in land use activities that may be influenced by change in atmospheric noise are discussed in **Section 5.3 Land Use**. Quality of Experience in Exercising Aboriginal Interests in the context of direct sensory disturbance to traditional users through Project-related changes noise is discussed in **Section 10 Aboriginal Consultation**. Potential influence of Project-related change in noise conditions on terrestrial wildlife (i.e., sensory disturbance) is discussed in **Section 4.8 Terrestrial Wildlife**.

4.10.3.3 Construction-Related Effects

Noise from Construction Activities other than Pile Driving

A generic analysis, originally developed for the Sea to Sky Highway Improvement Project and subsequently employed for the assessment of the Port Mann/Highway 1 Improvement Project and South Fraser Perimeter Road (Highway 17) Project, was adapted to fit Project conditions and used to estimate anticipated construction-related noise emissions. Factors considered during generic construction noise modelling, such as distance from the noise source, duration of construction activities, and setbacks from the highway, are listed in the technical volume, **Atmospheric Noise Study** included as **Section 16.6**.

Average construction noise levels predicted to be generated at various setback distances from a 200-m long, active construction zone due to cumulative noise output of all active heavy construction equipment are shown in **Table 4.10-2**. The levels presented are those that would be expected if the intervening ground was acoustically soft (i.e., grass, farms, or undeveloped land).

Table 4.10-2 Average Construction Noise Levels (L_{eq}) Expected Outdoors at Various Setback Distances from a 200 m-long, Active Construction Zone, Over Acoustically Soft Ground

| Major Construction Activity | Levels at Distances from a Typical 200-m Construction Zone (dBA) | | | | | | |
|--------------------------------|--|------|------|-------|-------|-------|-------|
| | 15 m | 30 m | 50 m | 100 m | 200 m | 400 m | 800 m |
| Clearing and grubbing | 82.5 | 78.0 | 74.5 | 69.0 | 60.5 | 51.0 | 39.5 |
| Excavation | 84.0 | 79.5 | 76.0 | 70.5 | 62.0 | 52.5 | 41.0 |
| Retaining walls and structures | 80.0 | 75.5 | 72.0 | 66.5 | 58.0 | 48.5 | 37.0 |
| Grading | 82.0 | 77.5 | 74.0 | 68.5 | 60.0 | 50.5 | 39.0 |
| Asphalt paving | 79.0 | 74.5 | 71.0 | 65.5 | 57.0 | 47.5 | 36.0 |

Construction noise exposures presented in **Table 4.10-2** are considered conservative since they assume construction activities are continuous throughout working hours. Typically, slowdowns and stoppages in construction activities occur.

More than one major construction activity may occur concurrently, which would have an additive effect on noise exposure. Such additive effects are small at locations close to the Project alignment, where construction noise levels are highest. Concurrent construction activity is anticipated to result in an increase in overall noise exposures of 1 dBA to 3 dBA at setback distances of 100 m to 200 m, and up to 4 dBA at distances of more than 400 m.

Noise from Pile Driving

Pile driving will occur during construction of the two bridge towers and the north and south bridge approach support piers. Due to the proximity of the new bridge and approaches to residential areas and Deas Island Regional Park, a more rigorous noise prediction method, CadnaA (described in more detail in **Section 16.6 Atmospheric Noise Study Technical Volume**) was applied for pile driving noise. Sound emission data (Environmental Protection Department 1997; expressed in L_{eq}) for a diesel impact hammer driving steel pipe piles was input to the CadnaA model to estimate pile driving noise levels at all noise-sensitive locations in the vicinity of the new bridge and approaches.

Ground-borne Vibration from Pile Driving

Pile driving will generate ground-borne vibration that may, at times, be perceptible at residences closest to the alignment. In such situations, ongoing vibration monitoring will be undertaken and pre-condition surveys of residences located closest to the piling areas conducted as appropriate.

Overall Estimated Construction-related Noise Effects

Project-related changes in noise levels at noise-sensitive receptors expected during construction are summarized below.

Maximum temporary construction noise levels at residential receptors are anticipated to range between 52 and 86 dBA L_d , with an average of 75 dBA L_d , for construction involving pile driving, and between 39 and 84 dBA L_{dn} , with an average of 75 dBA, for other activities.

At non-residential receptors (school, Places of Worship) along the Project alignment, temporary construction noise levels are estimated to range from 61 to 77 dBA L_{dn} , with an average of 71 dBA.

Maximum temporary daytime construction noise levels in various parks are anticipated to range between 52 and 65 dBA L_d , with an average of 58 dBA, during construction activities involving pile driving, and between 32 dBA and 57 dBA L_d , with an average of 46 dBA, during other construction activities.

4.10.3.4 Operational Effects

Predicted Project-related effects and estimated post-Project (2030) noise levels at the noise-sensitive receptors assessed as part of the noise studies are presented in **Table 4.10-5**. A brief overview of predicted future noise conditions with the Project at noise-sensitive receptors along the Project corridor, without mitigation, is presented below.

Residential Receptors

Predicted future (2030) noise levels:

- L_{dn} – 52.5 to 77.3 dBA, with an average of 68.3 dBA
- L_n - 42.9 to 70.1 dBA, with an average of 60.2.2 dBA

Existing (measured) noise levels:

- L_{dn} - 51.5 to 75 dBA, with an average of 66.3 dBA
- L_n - 41.3 to 67.8 dBA, with an average of 59.2 dBA

Passive Parks

Predicted future (2030) noise levels:

- L_d – 49.5 to 61.7 dBA, with an average of 55 dBA

Existing noise levels:

- L_d - 45.9 to 58 dBA, with an average of 49 dBA

Schools and Places of Worship

Predicted future (2030) noise levels:

- L_d – 65.3 to 75.2 dBA, with an average of 71.7 dBA

Existing noise levels:

- L_d - 61.7 to 71.8 dBA, with an average of 68.2 dBA

Deas Island Regional Park is the only park in the vicinity of the Project where readily perceptible Project-related changes to the noise environment could occur. Predicted effects of the Project within Deas Island Regional Park range from a 4 dBA increase in L_d at its eastern end (approximately 1,200 m from Highway 99), to an approximate 10 dBA increase at locations around 350 m to the east and west of the highway centreline. While noise mitigation for passive parks is considered on a case-by-case basis, post-construction noise levels within the park generally remain below levels that warrant mitigation consideration for residential and institutional use.

4.10.4 Mitigation Measures

This section outlines measures that will be implemented during Project construction and operation to avoid or minimize potential increase in noise levels at sensitive receptors. These measures will be informed by the Ministry's 2014 Noise Policy, and prior experience with comparable transportation infrastructure projects in the Lower Mainland.

4.10.4.1 Construction

Measures that will be implemented during Project construction to prevent or minimize potential effects on atmospheric noise will be outlined in a Construction Environmental Management Plan (CEMP), as described in **Section 12.0 Management Plans**. The CEMP will include a Noise Management Plan that describes standard best practices and Project-specific mitigation measures to prevent or minimize community impacts due to temporary, unavoidable construction-related noise. These measures may include, but not be limited to, the following:

- Control of noise at the source– Measures may be taken to reduce construction noise emissions at the source through the selection, appropriate operation, modification/enhancement and/or maintenance of equipment or processes. These measures include:
 - Turning off idling equipment such as diesel engines when not in use for more than 30 minutes.
 - Fitting all gas or diesel-powered equipment on site with intake (if appropriate) and exhaust silencers (i.e., mufflers) that meet manufacturer's recommendations for optimal attenuation and maintain these silencers in effective working condition.
 - Using hydraulic-powered equipment where appropriate/feasible.
 - Supplying and operating all equipment with appropriate covers, hoods, shields etc., in place and latched shut.
 - Carrying out regular maintenance on all equipment, including lubrication and replacement of worn parts, especially exhaust systems.
 - Operating all equipment at minimum engine speeds consistent with effective operation.
- Noise control along the source-receiver path–Community noise exposures may be reduced by blocking the dominant sound path (usually the line of sight) between the noise source zone and noise-sensitive receivers. For effectively shielded individual noise sources, noise reductions of 5 to 10 dBA may be achieved in this manner. Reductions in overall construction site noise emissions will generally be less and will depend on the degree to which all prominent noise sources can be effectively shielded. The following approaches to path noise control may be considered:
 - Where possible, locating and/or orienting noisy stationary equipment (e.g., compressors, generators) so as to take advantage of any inherent noise shielding available from the natural terrain, roadway fill or shoulder or other large objects (equipment, buildings, material piles) and to direct as little noise as possible towards nearby noise sensitive areas.

- When working in close proximity to noise sensitive areas and where no inherent shielding elements are available, locating temporary, perhaps portable, noise barriers close to fixed sources of noise such as compressors and generators. Use plywood, strand-board or other convenient, solid materials. If practical, the barrier will be made wider and higher than the noise source and line the source-facing surface with sound absorptive material such as 25 to 50 mm semi-rigid fiberglass insulation.
- Where permanent noise barriers are warranted to shield residents from operation (traffic) noise, installing them early in the construction phase, if possible, so as to shield construction noise as well.
- Selection of quieter equipment and processes—In some cases, construction processes can be selected that, by nature or design, produce less noise while doing similar work. Similarly, standard equipment or processes can be selected that have had additional noise control features added, such as better mufflers and enclosures on diesel or gas-powered equipment, exhaust silencers on air tools, etc. Equipment involved in any necessary night construction work near residential areas should be fitted with better-than-standard (i.e., "residential-rated") mufflers/silencers.
- Community engagement—Early engagement with communities on the scheduling of particularly noisy activities will help to reduce negative reaction to construction-related noise. As such, the following approaches are recommended for consideration:
 - Hold information meetings with community representatives throughout the Project corridor to identify site-specific construction activities and the timing of these activities. If there are any activities that must be done outside of regular work hours, the measures to be taken by the contractor to minimize the noise produced and/or received in the community should be discussed in advance.
 - Communicate with affected communities on a regular basis to advise them well in advance of the types of activities that will be taking place in the future (especially for pile driving, riveting and other operations involving noise impacts) and to notify them of any changes in the estimated start and/or completion dates for the various phases of construction. This can be achieved in a number of ways, including, but not limited to an information telephone line; and updates on the Project website (e.g. construction schedule with scheduled detours & traffic delays, electronic postcard updates with photos, construction bulletins, etc.).
 - Carry out monitoring of construction noise as appropriate to ensure mitigation measures are effective.

The above mitigation measures and best practices have been successfully implemented by the Ministry on comparable projects in the Lower Mainland, and are expected to effectively address construction-related noise.

4.10.4.2 Operation

The Ministry's 2014 noise policy provides a procedure to determine whether noise environments that will exist within adjacent communities ten years after completion of a highway project warrant mitigation consideration. Mitigation may be considered when the absolute post-project noise levels exceed certain fixed upper limits, and may also be considered when project-related changes in noise levels relative to pre-project conditions are predicted to be of certain magnitudes. The principal noise metric for residential areas is the L_{dn} , with fixed upper noise limits of 65 dBA for moderate impacts and 75 dBA for severe impacts. Details on mitigation thresholds under the Ministry's 2014 noise policy are provided in **Section 16.6 Atmospheric Noise Study Technical Volume**.

Noise impacts at residential receptors are classified as Severe under the noise policy if post-project total noise levels exceed a fixed threshold of L_{dn} 75 dBA, and Moderate if post-project total noise levels exceed a fixed threshold of L_{dn} 65 dBA. Classification of noise impacts under the policy also takes into account pre-Project noise levels and project-related change in noise levels. In cases where pre-Project noise levels are high, noise impacts due to a relatively small increase in noise level could be classified as Moderate or Severe, whereas in cases where pre-Project noise levels are low, noise impacts associated with a larger increase in noise levels may be classified as Minor (additional detail on noise impact classification under the Ministry's noise policy can be found in **Section 16.6 Atmospheric Noise Study Technical Volume**).

Predicted total noise levels and changes from existing noise levels at noise-sensitive receptors were compared against the mitigation thresholds under the Ministry's 2014 noise policy (see **Section 16.6 Atmospheric Noise Study Technical Volume**) to identify locations where Project-related noise mitigation may be required.

Table 4.10-5 identifies existing (2013) and predicted post-Project (2030) noise levels at noise-sensitive receptors (i.e., residences, schools, places of worship, and parks) along the Project alignment, and indicates whether the resultant noise impact warrants mitigation consideration under the Ministry's 2014 noise policy. The table also provides an overview of locations where Project-related mitigation considerations are warranted and the approximate spatial extent of such mitigation works. Mitigation measures will be implemented at these locations as warranted to meet the objectives of the Ministry's noise policy and achieve a minimum target noise reduction of 5 dBA. These measures identified in the Ministry's 2014 Noise Policy involve methodologies (e.g. noise barriers) that have been proven to be effective in mitigating traffic-related noise impacts associated with comparable projects. Noise mitigation measures will be integrated into Project design and construction to ensure that mitigation is effective when the Project becomes operational.

4.10.5 Residual Effects

Potential residual effects of the Project on atmospheric noise conditions are characterized with respect to the direction, magnitude, extent, duration, frequency, reversibility, and likelihood of each anticipated residual effect. Definitions for ratings applied to residual effects criteria, developed with specific reference to atmospheric noise are presented in **Table 4.10-3**.

A summary of criteria ratings for the potential residual effect is provided in **Table 4.10-5** and **Table 4.10-7** for operational phase noise and construction phase noise respectively. The context of the residual effects assessment (i.e., sensitivity and resilience to change, based on existing conditions) is also taken into account in characterizing potential residual effects of the Project.

Context: Existing (pre-project) traffic noise environments at several residential and other noise sensitive land uses (schools, places of worship) along the Project alignment are generally high. Such land uses would be sensitive to any increases in traffic noise that might be associated with the Project. With mitigation, however, residual effects of the Project on ongoing operational (traffic) noise exposures are generally expected to be positive, particularly at those locations which are closest to the alignment and therefore have the highest levels of existing noise. Temporary residual effects due to construction noise cannot be avoided, but will be minimized through the development and implementation of a construction noise control plan, which would include the employment of best practices. Notwithstanding, temporary construction noise levels will, at some residential locations (particularly near the bridge approaches where pile driving is required) and over some limited time periods, exceed the existing noise levels.

Table 4.10-3 Criteria Used to Characterize Residual Effects on Atmospheric Noise

| Criteria | Description | Definition of Rating | |
|-----------|--|----------------------|---|
| Direction | Overall nature of the residual effect | Adverse | Negative effect as a result of the Project. |
| | | Positive | Beneficial effect as a result of the Project. |
| | | Neutral | Neutral effect as a result of the Project. |
| Magnitude | Intensity of the effect relative to natural or baseline conditions | Negligible | No change in day-night average operational noise levels (L_{dn}). |
| | | Low | An increase in day-night average operational noise levels (L_{dn}) of 1 to 4 dBA. |
| | | Moderate | An increase in day-night average operational noise levels (L_{dn}) of 5 to 10 dBA. |
| | | High | An increase in day-night average operational noise levels (L_{dn}) of more than 10 dBA. |
| Extent | Geographic extent / distribution of the residual effect | Site | Effect is restricted to the immediate Project alignment. |
| | | Local | Effect is restricted to the LAA |
| | | Regional | Effect extends beyond the LAA |
| Duration | Length of time over which the residual effect is expected to persist | Short term | Effect occurs for a period of less than 3 months |
| | | Moderate term | Effect persists for up to 12 months |
| | | Long term | Effect persists beyond 12 months |

| Criteria | Description | Definition of Rating | |
|---------------|---|----------------------|--|
| Frequency | Nature of the occurrence of the residual effect (e.g., how often the stressor affects the IC) | Occasional | Less than 5 days a week, up to 8 hours/day |
| | | Frequent | Five or more days a week, up to 12 hours/day |
| | | Continuous | 7 days a week, up to 16 hours/day |
| | | Permanent | Permanent change |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after the disturbance has ceased (or after a period of time after the disturbance has ceased) | Reversible | Baseline conditions will be naturally restored after disturbance has ceased. |
| | | Irreversible | Baseline conditions will not be naturally restored after disturbance has ceased. |
| | | Change | Effect may fluctuate between positive and adverse for the duration of the disturbance. |
| Likelihood | Likelihood that the residual effect may occur | Low | Likelihood of residual effect is less than 25%. |
| | | Moderate | Likelihood of residual effect is between 25% and 75%. |
| | | High | Likelihood of residual effect is greater than 75%. |

4.10.5.1 Construction-related Residual Effects

During construction, mitigation measures and best practices as discussed in **Section 4.10.4.1**, including equipment and activity restrictions, appropriate scheduling of construction activities, noise monitoring, and community communication, will be implemented to minimize potential Project-related effects on ambient noise conditions. However, frequent construction noise will be experienced in areas near active construction sites. **Table 4.10-4** presents a summary of the criteria ratings for potential change in atmospheric noise conditions during construction activities.

Magnitude of residual construction noise effects will vary from low to high, depending on receptor location relative to construction site, and nature of construction activity. Effects will be short-term during construction of interchanges etc., and of moderate term during pile installation for the new bridge. During other construction activities, effects of lower magnitude will be experienced occasionally to frequently at receptor sites along the corridor for short durations. All construction-related effects on atmospheric noise will be temporary and fully reversible. Project-related changes in atmospheric noise levels are not expected to overlap temporally or spatially with similar effects of other project or activities and result in cumulative effects.

Table 4.10-4 Criteria Ratings for Residual Effect: Construction Noise

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|-----------|------------------------|--|
| Direction | Adverse | Construction noise will create adverse residual effects resulting in increases in total noise exposures relative to baseline traffic levels. |
| Magnitude | Low to High | Residual construction noise effects will vary substantially with receiver location and construction phase. Generally the magnitude of such residual construction noise effects will be low to Moderate. However, at some locations (within roughly 350 m of active pile driving at bridge approaches) and for some limited time periods, increases of more than 10 dBA may be experienced. |
| Extent | Local | Spatial extent will be restricted to within the LAA. |
| Duration | Short to Moderate term | Individual construction phases, including pile driving, within specific segments of the project corridor will have durations of one year or less. |

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|------------------------|--|
| Frequency | Occasional to Frequent | Within the various segments of the project, and during the various stages of construction, construction noise is expected to be present from less than 5 days per week and 8 hours per day, to seven days per week and up to 16 hours per day. |
| Reversibility | Reversible | Construction noise will cease upon completion of the project. |
| Likelihood | High | Construction noise residual effects will occur, but their magnitudes and durations will vary depending on nature and schedule of specific construction activities. |

4.10.5.2 Operation

Table 4.10-5 provides an overview of the predicted residual effects of the Project on community noise levels at all relevant noise receptors (residence, schools and places of worship, and parks), after implementation of mitigation measures in accordance with the Ministry’s 2014 noise policy. The ranges and average values of residual changes (i.e. change from existing noise levels) for each of these types of land uses are as follows:

- Residences: 0 to -7 dBA; average of -4 dBA
- School and Places of Worship: range of -2 to -1, average -1.5 dBA
- Parks: range 11 to 4 dBA

Note that a negative residual effect indicates that, with mitigation, post-Project noise levels will be lower than existing levels.

Table 4.10-5 Anticipated Project-related Changes, Mitigation Considerations and Residual Changes at Noise-Sensitive Receptors¹

| Site # | Location | Land Use | 2013 Baseline Noise Levels (dBA) | | Total Unmitigated Post-Project (2030) Noise Levels (dBA) | | Total Change from Baseline (before mitigation) | Mitigation Consideration Warranted under Noise Policy? | Location (extent) of Anticipated Mitigation Works | Total Post-Project (2030) Noise Levels after Mitigation ³ (dBA) | | Total Change from Baseline (after mitigation) |
|--------|---|----------------------|----------------------------------|----------------|--|----------------|--|--|---|--|----------------|---|
| | | | L _{dn} | L _d | L _{dn} | L _d | Δ (dBA) | | | L _{dn} | L _d | Δ (dBA) |
| 2 | 9700 block, Capella Drive, Richmond | Residential | 72 | - | 74 | - | 2 | Yes | Southbound on-ramp from Sea Island Way and along Hwy 99 (approximately 600 m). | 69 | - | -3 |
| 3 | 10100 block, Caithcart Road, Richmond | Residential | 70 | - | 72 | - | 2 | Yes | St. Edwards Drive between Bird Road and access road to Sandman Signature Hotel (approximately 150 m). | 67 | - | -3 |
| 4 | 10400 block, Hall Avenue, Richmond | Residential | 72 | - | 73 | - | 1 | Yes | Southbound Hwy 99 starting approximately 100m north of Kilby Drive to within 100 metres of Shell Road trail (approximately 750 m). | 68 | - | -4 |
| 4a | 10500 block, Kilby Drive, Richmond | Residential | 70 | - | 71 | - | 1 | Yes | Included in Site #4, see comment above. | 66 | - | -4 |
| 4b | 10300 block Bryson Drive, Richmond | Residential | 69 | - | 70 | - | 1 | Yes | Included in Site #4, see comment above. | 65 | - | -4 |
| 5 | 4500 block Dallyn Road, Richmond | Residential | 68.7 | - | 70.3 | - | 1.6 | Yes | North bound Hwy 99, starting approximately 170 m south of Shell Road trail and ending on shoulder of northbound Highway 91 on-ramp (approximately 450 m). | 65 | - | -3 |
| 6 | 11600 block Dewsbury Drive, Richmond | Residential | 74 | - | 76 | - | 2 | Yes | Included in Site #5, see comment above. | 71 | - | -3 |
| 7 | 12200 block Old Westminster Highway | Residential | 67 | - | 71 | - | 4 | Yes | Southbound on-ramp to Highway 99, extending to the west along Westminster Hwy. | 66 | - | -1 |
| 7a | Richmond Nature Park, 11800 block Westminster Highway, Richmond | Municipal - Park | - | 58 | - | 62 | 4 ² | No | N/A | - | 62 | 4 |
| 8 | 12200 block Old Westminster Highway, Richmond | Residential | 64.2 | - | 67.6 | - | 3.4 | Yes | Northbound off-ramp from Highway 99, extending to the east along Westminster Hwy (200 m to 300 m). | 63 | - | -2 |
| 9 | 12400 block Blundell Road, Richmond | Daycare/ residential | 73 | - | 77 | - | 4 | Yes | Northbound along Highway 99, extending 150 - 200 m to north and south of Blundell Road (300 m to 400 m). | 72 | - | -1 |

| Site # | Location | Land Use | 2013 Baseline Noise Levels (dBA) | | Total Unmitigated Post-Project (2030) Noise Levels (dBA) | | Total Change from Baseline (before mitigation) | Mitigation Consideration Warranted under Noise Policy? | Location (extent) of Anticipated Mitigation Works | Total Post-Project (2030) Noise Levels after Mitigation ³ (dBA) | | Total Change from Baseline (after mitigation) |
|--------|--|---------------------|----------------------------------|----------------|--|----------------|--|--|--|--|----------------|---|
| | | | L _{dn} | L _d | L _{dn} | L _d | Δ (dBA) | | | L _{dn} | L _d | Δ (dBA) |
| 10 | 12200 block, Blundell Road, Richmond | Daycare/residential | 67 | - | 70 | - | 3 | Yes | Southbound along Highway 99, south of Blundell overpass (250 m to 300 m). | 65 | - | -2 |

Notes:

- Numbers shown in the table have been rounded off to nearest whole decibels except in cases where such rounding off would result in an erroneous representation of post-Project conditions in the three rightmost columns. In such cases, the tenth decibel has been retained.
- Where warranted under the Ministry's 2014 Noise Policy, a minimum mitigation objective of 5 dBA noise level reduction at the receptor sites will be applied.
- This is the projected change in Highway 99 traffic noise; however, overall noise levels at this site are not dominated by Highway 99 noise, and the actual Project-related noise increase will be lower than indicated here.
- The Ministry's 2014 noise policy specifies that for educational institutions, the potential need for mitigation must be investigated where post-project noise levels at a school facade are predicted to be Leq(max-hr) 60 dBA or higher. This will often involve measurement of (post-project) noise levels inside unoccupied classrooms. The target minimum noise level reduction objective of 5 dBA will be applied to these receptors.
- Under the Ministry's 2014 noise policy, the same impact thresholds as specified above for educational institutions apply to places of worship. Given the setback distance of the temple from the highway, which influences mitigation effectiveness, the need for mitigation and appropriate mitigation approach at this location will be determined by post-construction interior noise level monitoring. The target minimum noise level reduction objective of 5 dBA will be applied to this receptor as well.
- This is the projected change in Highway 99 traffic noise; however, overall noise levels at this site are not dominated by Highway 99 noise, and the actual Project-related noise increase will be lower than indicated here.
- This receptor would benefit from mitigation treatment at River Woods; however, this reduction in noise levels is not considered in the post-Project noise levels presented.
- This receptor would benefit from mitigation treatment at for Captain's Cove; however, this reduction in noise levels is not considered in the post-Project noise levels presented.
- Overall noise exposures at this site are controlled by railway activities; no Project-related influence on noise is anticipated, and therefore future noise predictions were not made.
- Overall noise exposures at this site are controlled by railway activities no Project-related influence on noise is anticipated, and therefore future noise predictions were not made.

As can be seen in **Table 4.10-5**, with the application of mitigation measures (e.g. noise barriers) in accordance with the Ministry’s Noise Policy, post-construction ambient noise levels at most residential and institutional receptors along the Project alignment are predicted to be lower than current levels. This long-term operational residual effect of the Project on noise conditions at residential and institutional receptors are considered to be positive, and of negligible to low magnitude.

Once the new bridge becomes operational, noise levels within Deas Island Regional Park, specifically in proximity to the bridge approach, will increase, but will generally remain below levels that warrant mitigation consideration for residential and institutional use.

Table 4.10-6 presents a summary of the criteria ratings for Post-construction residual effects.

Table 4.10-6 Criteria Ratings for Residual Effect: Operational Noise

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-------------------|--|
| Direction | Positive | Overall, residual (with mitigation) effects will be positive |
| Magnitude | Negligible to Low | Typical residual effects in residential areas will be between -1 and -7 dBA (i.e., approx. perceived loudness reductions of from 7 to 38%) |
| Extent | Local | Spatial extent will be restricted to the LAA – 500 to 1500 m.. |
| Duration | Long term | Effects will persist into future; 10 years or more. |
| Frequency | Permanent | Effects will exist on a daily basis well into the future. |
| Reversibility | Irreversible | Operational noise levels will persist at or near predicted levels as long as traffic conditions are relatively free flowing. |
| Likelihood | High | Changes in operational noise levels are quite certain to occur. Likelihood greater the 75%. |

4.10.6 Cumulative Effects and their Significance

The combination of Project-related changes and changes from other present and certain and reasonably foreseeable future projects and activities, listed in **Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**, comprise the total cumulative changes to atmospheric noise. This section provides an assessment of these cumulative changes.

Short-term noise exposures are unavoidable especially during Project-related construction activities. However, implementation of standard industry and best practices, informed by the Ministry's experience with prior projects of similar scale and nature, will minimize residual changes in atmospheric noise to the extent practically possible.

Changes in overall traffic noise levels associated with any other certain or reasonably foreseeable projects within the Project alignment are anticipated to be small during Project construction. It has therefore been assumed that cumulative changes due to the interaction of any such increase in non-Project-related traffic noise with Project-related construction noise would be negligible.

A list of other certain and reasonably foreseeable projects and activities that could interact with a Project-related change to atmospheric noise (operation phase) and result in a cumulative change is presented in **Table 4.10-7**. A map showing the locations of these projects and activities in relation to the Project is included as **Figure 3.10-2** in **Section 3.10**. The types of potential cumulative change resulting from these interactions are described below.

Road traffic growth associated with major projects (e.g., Roberts Bank Terminal 2, Fraser Surrey Docks) planned within or near the Project alignment has been considered in the Ministry's EMME 2 traffic modelling, and therefore was included in the 2030 Highway 99 traffic volumes used in the atmospheric noise assessment.

The increase in daily average noise exposures with traffic volume is very gradual, about 3 dBA per doubling of total traffic volume, all else being equal. For example, if, conservatively, over a 10-year period all foreseeable projects in or near the Project alignment collectively resulted in a 15% increase in total daily traffic on Highway 99, the increase in daily average traffic noise exposures from Highway 99 traffic (expressed in terms of L_{dn}) would be 0.6 dBA and would be imperceptible.

Projects that could increase the volumes of other types of transportation movements in the Project alignment are provided in **Table 4.10-7**. These include rail movements along the Canadian National Railway line paralleling Highway 99 to the south between 72 and 96 streets as a result of Roberts Bank Terminal 2, and increased vessel traffic on the Fraser River South Arm beneath the new bridge, as a result of the Vancouver Airport Fuel Delivery project, Fraser Surrey Docks Direct Transfer Coal Facility (Texada Coal), and WesPac LNG Marine Jetty Project. While these transportation-related noise events are expected to be audible, they will be transient, not present for long enough to interact with Project-related noise effects, and are not expected to contribute in a measurable or readily perceptible way to the daily average noise levels. At locations where noise from Project operations will be audible, the average daily noise levels are expected to be dominated by the continuous noise created by new bridge traffic.

Table 4.10-7 Potential Cumulative Changes Due to the Interaction of Other Certain and Reasonably Foreseeable Projects on Atmospheric Noise

| Other Certain and Reasonably Foreseeable Project | Relevant Source of Change | Anticipated Change | Anticipated Cumulative Change |
|---|--|--|--|
| Roberts Bank Terminal 2 | Increase in rail traffic volumes on rail line parallel to Highway 99 between 72 and 96 streets | Increase in numbers of relatively low level rail noise events experienced at rural residences along west side of Ladner Trunk Road approximately 700 m east of rail line | Cumulative change in overall daily noise exposure will be very minor |
| Vancouver Airport Fuel Delivery Project | Increase in vessels transiting the Fraser River South Arm beneath the new bridge | Increase in noise levels in Fraser River South Arm beneath new bridge | No incremental cumulative change expected. Noise from ships in transit is not present long enough to interact with Project noise and is not expected to measurably affect 24-hour average noise levels |
| Fraser Surrey Docks Direct Transfer Coal Facility (Texada Coal) | Increase in vessels transiting the Fraser River South Arm beneath the new bridge | Increase in noise levels in Fraser River South Arm beneath new bridge | No incremental cumulative change expected. Noise from ships in transit is not present long enough to interact with Project noise and is not expected to measurably affect 24-hour average noise levels |
| WesPac LNG Marine Jetty Project | Increase in vessels transiting the Fraser River South Arm beneath the new bridge | Increase in noise levels in Fraser River South Arm beneath new bridge | No incremental cumulative change expected. Noise from ships in transit is not present long enough to interact with Project noise and is not expected to measurably affect 24-hour average noise levels |

In summary, no cumulative changes of readily measurable or perceptible magnitude are predicted within the Project alignment. A small cumulative change is identified as the combined effect of projects on traffic volumes on Highway 99 and other components of the roadway system. However, such traffic growth is expected to have been included in the EMME 2 traffic modelling for the Project and hence in the 2030 noise predictions made herein.

4.10.7 Follow-up Strategy

During Project construction, monitoring of construction noise will be undertaken as appropriate to ensure mitigation measures are effective.

Once the new bridge and upgraded highway become operational, and traffic patterns have stabilized (no more than a year after completion), post-project, 24-hour noise monitoring will be carried out at selected, representative noise receiver locations. Such monitoring will serve to both confirm noise predictions and to assess the effectiveness of mitigation measures.

"N/A" indicates that no Project works and/or activities are applicable to the category

5.1 Traffic Assessment Highlights:

- The Project has been designed to address issues related to current and future traffic safety, congestion and reliability, and to help achieve regional mode share targets by facilitating travel across the Fraser River by transit, HOVs, cycling, and walking.
- With implementation of recognized mitigation measures and best management practices, impacts to traffic during Project construction will be minimized.
- During operations, the Project will provide travel time savings of 25-35 minutes per day for commuters, improve safety with a forecast 35% reduction in collisions, and support provincial and regional strategies to encourage mode shift to transit and carpooling.
- As proposed, Project-related improvements, which include better travel mode options, and tolling will help moderate traffic growth while effectively serving forecast demand at the crossing.
- The Project will have a positive effect on future traffic conditions along the Highway 99 corridor.

5.1 Traffic

This section describes the existing conditions related to traffic safety, traffic volumes, congestion, and mode share, and the anticipated changes resulting from Project components and activities. Traffic is studied as an intermediate component (IC), and the information presented on predicted changes in traffic, with and without the Project, is used to support the assessment of potential Project-related effects on terrestrial wildlife (**Section 4.8**), atmospheric noise (**Section 4.10**), air quality (**Section 4.9**), land use (**Section 5.3**), and human health (**Section 7.1**).

Relative to VCs and other ICs assessed in the Application, traffic is unique because changes in traffic conditions are both a potential effect and also a primary objective that supports the Project rationale. Specifically, addressing existing adverse effects of congestion on the movement of people and goods and efficiently operating the local and regional road network are fundamental goals. The Project was developed to address current and anticipated traffic challenges that are resulting in adverse effects on environmental, economic, social, and health values. In this context, the effects of the Project during operation will be positive. **Section 1.1.10 Benefits** provides a summary of benefits associated with the Project.

5.1.1 Context and Boundaries

This section describes the context for assessing Project-related effects on traffic, and defines the spatial, temporal, administrative, and technical assessment boundaries. The rationale for selecting the assessment boundaries as defined is also provided.

5.1.1.1 Assessment Context

The Project involves changes to the Highway 99 corridor and related road, transit, and cycling and pedestrian networks that influence the movement of people and goods, as represented by changes in future traffic volumes, traffic flows, origins and destinations, and travel mode choice. Project-related changes to the road network have been designed to facilitate travel time savings and reduced idling, while providing greater travel time reliability and substantial safety improvements, which will result in health benefits. These changes will also offer improved community connections across the Highway 99 corridor while helping to reduce congestion on adjacent municipal streets, which can provide future benefits to local area social and economic values. Changes in traffic conditions have the potential to affect noise, air quality, land use, and terrestrial wildlife.

Changes to existing transit infrastructure along the Highway 99 corridor that have been integrated into the Project design are intended to result in travel time savings, improved travel time reliability, and greater travel mode choices. These changes can provide future benefits to social, economic, health, and environmental values, both locally and regionally.

Expanding pedestrian and cycling networks in the Highway 99 corridor, as part of the design of the Project, will also enhance travel mode choices, which in turn facilitate healthy lifestyles and improved access to recreational activities.

5.1.1.2 Methodology

The assessment of traffic follows the general methodology described in **Section 3.0 Assessment Methodology**. In early 2013, the Ministry initiated desktop studies, traffic data collection, and traffic forecast modelling to support Project planning and the assessment of potential Project-related effects. These studies focus on projected traffic conditions within the Project corridor during construction and operation. Results will be discussed in terms of:

- Safety
- Traffic volumes
- Mode share
- Travel time and reliability

5.1.1.3 Assessment Boundaries

Spatial, temporal, administrative, and technical boundaries identified for the assessment of Project-related effects on traffic, and the rationale for selecting them, are discussed below.

Spatial Boundaries

The Project alignment extends from Bridgeport Road in Richmond to Highway 91 in Delta. The spatial scope of the traffic assessment is divided into a local assessment area (LAA) and a regional assessment area (RAA) as shown in **Figure 5.1-1** and summarized on **Table 5.1-1**.

The LAA considers the spatial area of physical works proposed to be undertaken and includes the Highway 99 right-of-way (ROW) from Bridgeport Road in Richmond to Highway 91 in Delta. Where the physical scope of the Project extends beyond the ROW to tie into connecting highways and roads, the LAA has been widened to match the physical scope.

The RAA is defined as the Greater Vancouver region as represented in TransLink’s Regional Transportation Model (RTM), which incorporates Metro Vancouver’s future land use plans, population and employment growth forecasts, goods movement forecasts, changes that may be made to the regional transportation infrastructure (roads and transit), and decisions that individuals and goods movers are likely to make regarding regional transportation travel and mode choices.

Information on traffic conditions within the RAA, presented in **Section 5.1.2**, provides context for the assessment of potential changes to traffic in the LAA. Such information includes traffic forecasts on adjacent highway corridors and nearby bridges with and without the Project and a discussion of key trends.

Table 5.1-1 Spatial Boundaries for Traffic Assessment

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|---|
| Local Assessment Area (LAA) | Project alignment, including Highway 99 right-of-way from Bridgeport Road in Richmond to Highway 91 in Delta. Where the physical scope of the Project extends beyond right-of-way in order to connect other highways and roads, the LAA has been widened to match the physical scope. |
| Regional Assessment Area (RAA) | The Greater Vancouver Region as represented in TransLink’s Regional Transportation Model. |

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on traffic were established based on the potential for each phase of the Project to interact with and have an effect on traffic. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, both the construction and operational phases of the Project include components and activities that may interact with and affect traffic; therefore, the following temporal boundaries were defined for the traffic assessment:

- Existing conditions
- Project construction, including Tunnel decommissioning
- Project operation, including maintenance

Temporal characteristics of the Project phases are discussed in **Section 1.1 Description of the Proposed Project**. Specific temporal considerations for the assessment of traffic and its sub-components are discussed in the context of Project interactions and potential effects in **Section 5.1.3**.

Administrative Boundaries

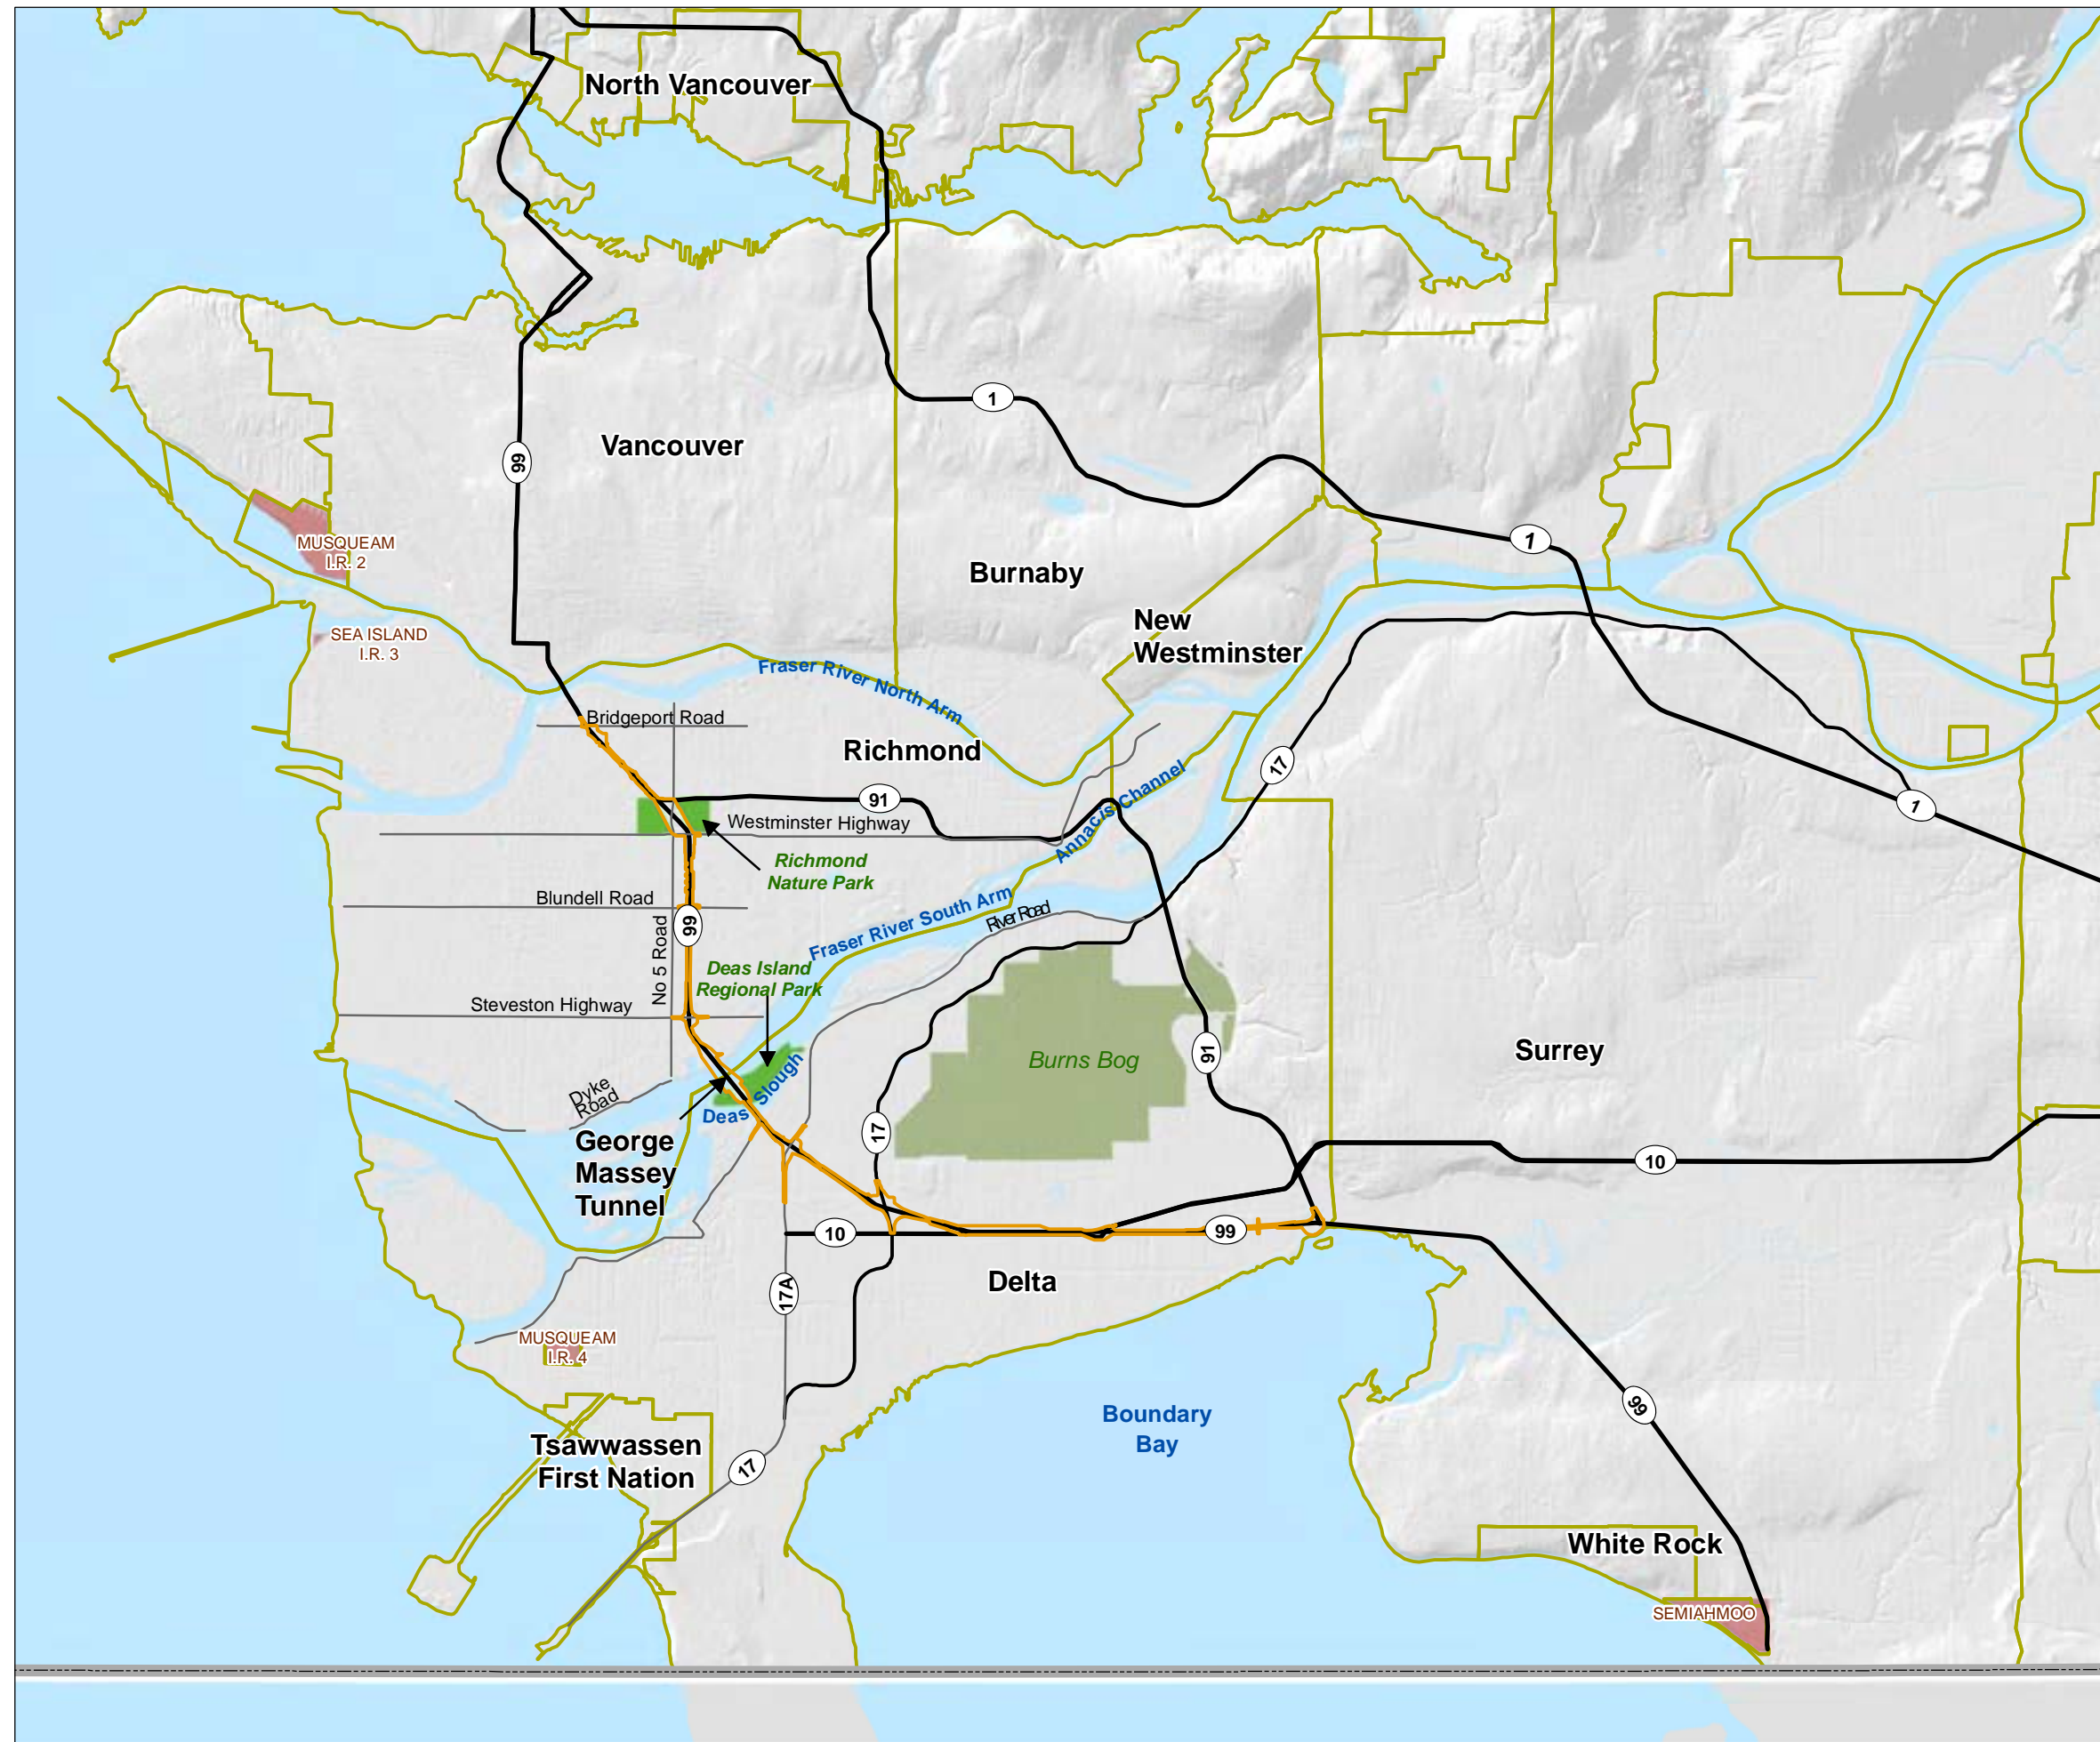

No economic, social, or political constraints have been identified that could impose limitations on the assessment of potential Project-related effects on traffic; therefore, no administrative boundaries are defined.

Technical Boundaries

Traffic forecasting is based on assumptions regarding the timing of land use plans build-out, population and employment growth, and future changes to regional transportation infrastructure, as well as decisions that individuals will make regarding transportation choices. As such, there is some inherent uncertainty in the predictive capacity of traffic models. Such uncertainty has been mitigated by using multiple methodologies and considering a range of forecasts.

Provincial *Guidelines for Tolling* (B.C. MOTI 2003) have been used as the basis for assumptions related to traffic forecasts that include tolling. Specifically, the Port Mann Bridge tolling framework has been applied to the new bridge, with the adjacent Alex Fraser Bridge (AFB) and Highway 91 corridor considered as the free alternative. Tolling is discussed in more detail in **Section 1.1.7.3 Project Operations and Maintenance**.

The Ministry recognizes current discussions about the possibility of regional tolling or other forms of road pricing in Greater Vancouver. Such changes, if implemented, would affect all Fraser River crossings and the underlying RTM assumptions about traffic movements. However, as uncertainty exists about the specific framework that might be adopted or when it would be put into place, the existing tolling framework is considered the best currently available technical information for the purposes of this traffic assessment.

5.1.2 Existing Conditions

This section discusses anticipated interactions of Project components and activities with traffic, and potential effects of such interactions on traffic volumes, patterns, and mode share. Information on the mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 5.1.4**. Residual effects (i.e., effects remaining following the implementation of mitigation measures) are described in **Section 5.1.5**.

5.1.2.1 Baseline Data Collection

The objective of the traffic assessment is to develop an understanding of current and future traffic conditions to support the prediction of potential Project-related changes in traffic in the LAA. Baseline data collection to support the assessment commenced in 2013, and includes:

- Desktop studies to review past planning studies and traffic data to understand historical trends and identify data gaps
- A review of regional transportation and growth management plans
- A traffic data collection program to study traffic volumes, mode share (cars, trucks, buses, cyclists, passengers, etc.), origin-destinations, and travel time reliability and congestion along the Highway 99 corridor and adjacent major routes and bridges
- Traffic forecasting (modelling) to predict future conditions, with and without the Project, using several methodologies

Data collection sources, and reports created from the data collection program are summarized in **Appendix B, George Massey Tunnel Replacement Project Traffic Data Overview**.

5.1.2.2 Regulatory Context

The two pieces of legislation relevant to the Project in the context of traffic include the *Transportation Act*, S.B.C. 2004, c. 44, and the *South Coast British Columbia Transportation Authority Act*, S.B.C. 1998, c. 30.

The *Transportation Act* deals with public works related to transportation, as well as the planning, design, holding, construction, use, operation, alteration, maintenance, repair, rehabilitation and closing of provincial highways. The act also enables the designation of arterial and controlled access highways.

The *South Coast British Columbia Transportation Authority Act* provides the mandate for the South Coast British Columbia Transportation Authority to manage and operate the regional transportation system, develop and implement transportation demand management strategies and programs, generate and manage funds necessary for its purpose, and prepare and implement strategic, service, capital and operational plans for the regional transportation system.

In addition to the above legislation, the Ministry's Guidelines for Tolling (MOTI 2003) would apply to tolling of the new bridge.

5.1.2.3 Existing Conditions

Since opening in 1959, traffic demand and the needs of Highway 99/Tunnel users have changed substantially. Today, an average of 80,000 vehicles use the Tunnel every day. In addition, influences on transportation infrastructure along the Highway 99 corridor have changed including origins and destinations within the corridor and the demand for greater transportation choice.

While the Tunnel remains an important commuter crossing to City of Vancouver (Vancouver) for south of the Fraser River residents, travel patterns within the Lower Mainland in general, and south of the Fraser River in particular, also have changed substantially since the Tunnel opened. At present, traffic to Vancouver accounts for only 40 per cent of the total traffic through the Tunnel, while almost 60 per cent of daily trips are between Richmond and communities south of the Fraser River.

This section presents a discussion of existing conditions in the Highway 99 corridor in terms of safety, traffic volumes and mode share, and travel time and reliability. A brief overview of the relationship between traffic movements on Highway 99 and Highway 91/AFB is also provided.

Information obtained from the baseline data collection program that supports the description of existing traffic conditions is presented in **Appendix B**.

Traffic Safety

Traffic safety is assessed by comparing collision rates for a segment of a roadway to provincial averages for the same roadway type and classification. The average collision rate is measured in units of collisions per million vehicle kilometers (c/mvk), and provides a measure of the frequency of collisions in the study segment. An assessment of collision rates for the LAA is presented in the report titled *George Massey Tunnel Replacement Project Collision Data Analysis* (Delcan 2015).

Results show that the segment of Highway 99 which includes the Steveston Highway interchange, the Tunnel, and the Highway 17A interchange, has an average collision rate of 0.44 c/mvk, which is much higher than the 0.30 c/mvk provincial average (Delcan 2015).

These high traffic collision rates present an ongoing risk to safety and human health. The Steveston Highway interchange has the highest number of collisions along the assessment corridor, including relevant nearby intersections and roadways. There were 625 collisions at this interchange between 2008 and 2012. Additionally, the Steveston Highway/No. 5 Road intersection, immediately west of Highway 99, had the second highest number of collisions (545) during this period. There were 491 collisions at the Highway 99/Highway 17A interchange between 2008 and 2012, which is the third highest number of collisions along the study corridor (Delcan 2015).

Anecdotal evidence suggests that driver behaviour specific to the Tunnel contributes to safety concerns – some drivers brake or slow down upon entering the Tunnel to adjust to the Tunnel's low clearances, narrow lanes, and low lighting built to 1950s standards. Currently, approximately one half of Tunnel collisions involve an injury (Delcan 2015). Congestion and access-related delays in emergency responders' access to the Tunnel, to attend to vehicle collisions, are an additional safety concern. Counter-flow operation leads to opposing traffic travelling side-by-side without median separation, which causes driver discomfort and is a potential safety concern.

Traffic Volume and Mode Share

Since the Tunnel opened in 1959, the volume of traffic along the corridor has steadily increased as the population and economy of Metro Vancouver have grown. The Tunnel currently carries an average of 80,000 vehicles each day, and without the new crossing, traffic through the Tunnel will grow to approximately 100,000 vehicles per day by 2045 (MOTI 2015d). In addition to growth in traffic on Highway 99 since it opened, the profile of users (mode share) of the corridor and Tunnel has changed. This section presents an overview of the profile of the range of current users of the corridor, including trucks, transit, and cyclists, and their present and emerging needs.

Trucks – Highways 99 and 91 are key components of the regional truck transportation network that supports local, provincial, and international trade. During the work week, 7,000 trucks per day use the Tunnel, while 9,000 trucks per day use the AFB. Truck traffic has grown by over nine per cent at all major river crossings in the Lower Mainland from 2008 to 2014, with increases of nine per cent and 5.4 per cent at the Tunnel and AFB respectively (CTS 2008, Acuere 2014).

It is important to note that more than 50 per cent of truck traffic crosses the Fraser River South Arm (Tunnel and AFB) during the midday (TransTech 2009, TransLink 2013a). This is due in part to heavy congestion at these crossings during peak periods, which trucks avoid. Therefore, the midday period at these crossings is also becoming increasingly congested.

Current conditions also create inefficiencies for commercial and agricultural businesses, including scheduling traffic movements during congested periods and navigating poor connections across Highway 99.

Transit – During the morning rush hour, approximately 60 per cent of trips to downtown Vancouver by residents of South Delta and South Surrey are made by transit. The Tunnel has the highest number of buses crossing the Fraser River daily, connecting buses from transit exchanges in South Surrey and Ladner to the Bridgeport Road Canada Line station in Richmond. On an average weekday, 559 buses carry 10,535 passengers through the Tunnel (TransLink 2013a). Nine northbound TransLink bus routes use the Tunnel during the morning rush period; this equates to a bus every two to three minutes (TransLink 2014). While northbound morning rush hour buses comprise only one per cent of traffic, they carry approximately 17 per cent of all Tunnel travellers (TransTech 2014).

High-Occupancy Vehicles (HOV) – Highway 99 has some of the highest HOV use in the region. A key driver of this high mode share is Highway 99 and the Tunnel's proximity to gateways in the region, including the Tsawwassen Ferry Terminal and the Canada–U.S. Border. HOV use through the Tunnel is heaviest on weekends, when HOVs account for 40 per cent of total vehicles and transport 56 per cent of total passengers (TransTech 2014).

During weekdays, HOVs represent 10 per cent of northbound weekday commuter Tunnel traffic, carrying 16 per cent of passengers; and 17 per cent of southbound weekday commuter Tunnel traffic, carrying 25 per cent of passengers (TransTech 2014).

Transit and HOV traffic enjoy high utilization and obvious benefits in terms of the queue-jumper access to the Tunnel during periods of high congestion. However, given the high proportion of goods movement, services, and extra-regional trips through the Tunnel each day for which transit and HOV travel is not a viable option, analysis indicates that improvements in HOV and transit alone will not substantially address the current Highway 99 traffic challenges.

Cycling – Currently, cyclists and pedestrians are not permitted to use the Tunnel for safety reasons. In the absence of a viable alternate route for these travellers, the Ministry operates a year-round free shuttle service through the Tunnel. In 2014, the shuttle transported an average of 910 people per month. Demand is higher in the summer, but averages 30 people per day

over the year (Mainroad 2014). The shuttle service does not operate on weekends during the winter months. The new bridge will include a multi-use pathway on either side for cyclists and pedestrians, eliminating the need for the shuttle service.

Highway 91/Alex Fraser Bridge Traffic

While the Highway 99 corridor and Tunnel provide a critical component of the regional road network, they also operate in concert with the adjacent Highway 91 and Alex Fraser Bridge. Together, the Tunnel and AFB serve traffic demand between Surrey and Delta and communities in Richmond and north of the Fraser River. Combined traffic growth at these two crossings has averaged 0.64 per cent per year between 2003 and 2013 (see Section 2 of **Appendix B**). However, during this period, due to lack of available capacity at the Tunnel, the AFB has absorbed this growth.

Travel Time and Reliability

The four-lane Tunnel operates with a counter-flow system during the commuter rush periods, with only one lane open in the non-peak direction. Traffic volumes in the non-peak direction have grown steadily over the past 15 years. Traffic volumes outside of the rush periods have also grown to the point where the Tunnel is close to capacity throughout the day (B.C. MOTI 2015b).

Due to the fact that traffic demand exceeds Tunnel capacity, Tunnel congestion currently accounts for more than one million hours of vehicle delay annually. Congestion within the corridor is defined by variable and unpredictable delays throughout the day. Key trends include the following:

- Despite the three lanes available (counter flow) during the morning peak for northbound traffic, there is congestion from just after 6:00 a.m. until 10:30 a.m. Delays associated with this congestion are typically 5 to 10 minutes, but can often be as high as 23 minutes.
- Congested conditions return from 3:00 p.m. until after 6:00 p.m. when the counter-flow system reduces the northbound traffic to one lane. This results in typical delays of 20 to 50 minutes.
- Southbound traffic is reduced to one lane during the morning peak period, which results in congestion with delays up to 20 minutes from just after 6:00 a.m. to just after 9:00 a.m.
- Conditions are again congested, with delays up to 15 minutes, from 3:00 p.m. until 6:00 p.m., despite the three lanes available via the counter-flow system (B.C. MOTI 2015c).

5.1.2.4 Traffic Forecasting

Forecasts were undertaken to assess Project-related changes in traffic in the LAA by comparing existing conditions and future conditions with and without the Project. This section provides a description of the methodologies used to develop such traffic forecasts.

In the Metro Vancouver region, traffic demand forecasts are developed using a computer-based transportation planning tool called EMME2 (a bilingual acronym for multimodal equilibrium/équilibre multimodal). TransLink develops and maintains models using this software, including the regional assumptions used as inputs to the model, and distributes updates, as appropriate, to planning agencies for the purposes of transportation project planning and assessments.

Traffic forecasts were developed for the LAA and RAA using TransLink's models for scenarios with and without the Project, as well as with and without tolling. Alternative forecasting methods were also used to further analyze and substantiate traffic forecasts for the new bridge and Highway 99 improvements.

Traffic Modelling

In 2012, the Ministry retained Parsons Corporation (Parsons), a recognized transportation engineering consulting firm, to develop forecast traffic volumes for the Project using TransLink's regional transportation planning models. Over the four-year planning period for the Project, the following models have been used:

EMME2 Gateway Program (GSAM) Model

The GSAM model was collaboratively developed by the Ministry and TransLink, and used to model forecast demand to 2031 for the Gateway Program projects from 2003 to 2009. The Ministry updated and used this model again in 2012 and 2013 during the early planning stages of the Project. The GSAM model forecasts were used to test TransLink's new EMME2 model, which was released for use in 2014.

EMME2 Regional Transportation Model (RTM)

This is the latest transportation demand model developed and maintained by TransLink. The RTM contains two road networks (2011 and 2045), and is based on land use assumptions consistent with Metro Vancouver's Regional Growth Strategy (RGS) (2014). A number of alternative future scenarios are also included in the RTM, primarily reflecting different levels of investment in transit.

As advised by TransLink, the RTM forecasts used for the Project are based on the Alternative 3 regional network scenario. This scenario assumes that the transportation priorities outlined in the Mayors Council Vision *Regional Transportation Investments, a Vision for Metro Vancouver* (Mayors' Council 2014) have been implemented. These priorities include a new four-lane Pattullo Bridge, upgrades to the major road network (MRN), the Evergreen and Broadway rapid transit extensions, light rail transit in Surrey and Langley, expanded bus and Sea Bus services, and expanded pedestrian and cycling networks.

TransLink provided the RTM State 0 (Beta) version of the model to the Ministry's Project team in 2014, and initial results were compared to the GSAM forecasts. Differences in traffic forecasts between the two models indicated a need to upgrade RTM State 0 with newer road and transit networks; updated truck trip generators from airports, port facilities (e.g., Roberts Bank Terminal 2 expansion), and industrial areas; new major developments; and updated Canada-U.S. border traffic for cars and trucks. These updates were carried out and provided to TransLink. Subsequent modelling for the Project has used the RTM State 0 version with these updates.

Modelled Forecast Adjustments

TransLink continues to carry out updates and model calibrations, but the RTM remains primarily a regional model for long term forecasting. Considering this, and to provide confidence that the traffic forecasts required to support the environmental assessment are robust and based on reasonable assumptions, the Ministry also commissioned an in-depth research and analysis program to consider alternative methods for developing traffic forecasts for the Project. The following section provides an overview of alternative information that was obtained and considered to strengthen confidence in the modelled traffic forecasts noted above.

Historic and Current Tunnel Traffic Growth and Delay Patterns

A comprehensive analysis of long-term traffic growth patterns at the Tunnel, AFB, and other Fraser River crossings was undertaken. While the Tunnel has been congested for many years, AFB has absorbed most of the area's traffic increases over the past decades. Analysis showed that traffic has now increased to the point where both the Tunnel and AFB face significant peak-direction congestion and delays during rush hours. Between 2003 and 2013, combined traffic growth at the Tunnel and AFB averaged 0.64 per cent annually (B.C. MOTI 2015c). This information was used to support sensitivity analysis of modelled demand at the Tunnel.

Historic Truck Traffic Growth

A number of key sources of truck traffic information were reviewed including traffic count station data, TransLink screenline surveys (TransTech 2009, TransLink 2013a), and the *Metro Vancouver Truck Classification and Dangerous Goods Survey* (CTS 2008, Acuere 2014). Between 2008 and 2014, Tunnel truck traffic increases averaged 1.4 per cent annually (CTS 2008, Acuere 2014). This confirmed the need for RTM adjustments to truck forecasts. In the meantime, modelled truck forecasts were adjusted upward to reflect the additional demand.

Origin-Destination Travel Surveys

A detailed analysis of 2013 and 2014 origin-destination travel patterns was performed for the Project and Highway 91/AFB traffic, by time of day and day of week. This data collection and analysis provided essential information for forecasting shifts in traffic patterns caused by the new bridge. As previously noted, almost 60 per cent of daily vehicle trips through the Tunnel are between Richmond and communities south of the Fraser River. In addition, some AFB trips appear to be for the purpose of avoiding Tunnel congestion, despite Highway 99 offering a more direct route (Parsons 2015). These findings provided a greater level of confidence in the modelled results at the Oak Street Bridge, which show little change at the Oak Street during peak hours with or without a new bridge to replace the Tunnel.

Future Population and Employment Growth

The Metro Vancouver RGS and other regional and community planning initiatives were reviewed, including commercial and industrial economic development opportunities, and the anticipated population and employment growth for Richmond, Delta, and Surrey. Between 2011 and 2041, the RGS forecast is for more than a 50 per cent increase in population and employment in these communities. These very high growth rates provided further confidence in continued increase in demand for travel in the future, even with the significant investments in transit that are assumed in the RTM.

Evaluation of Port Mann Bridge Experience

A detailed analysis of the traffic pattern changes, by hour of day and day of week, for the new Port Mann Bridge was undertaken to identify lessons learned that should be applied to traffic forecasting for this Project. This analysis confirmed implementation of tolls at Port Mann Bridge resulted in a 14 per cent drop in traffic between 2011 and 2014 (no tolls to full tolls). In the following year, however, the Port Mann Bridge traffic grew by more than four per cent (B.C. MOTI 2015c). Developing a comprehensive understanding of the actual traffic impacts at the Port Mann Bridge has been key to developing traffic forecasts associated with this Project.

Independent Forecast

Independent of the Project team’s traffic forecasts for the new bridge, international transportation consulting firm Steer Davies Gleave (SDG) developed traffic forecasts for the Project, considering a tolling regime similar to the current Port Mann Bridge. SDG’s report, *George Massey Tunnel Replacement – Traffic Forecasts*, is included as **Appendix C**.

5.1.2.4.1 Local Assessment Area Traffic Forecasts

The following section presents various traffic forecasts that have been undertaken as part of Project planning to support Project design as well as assessment of traffic in the LAA.

In consideration of the limitations and uncertainties involved in traffic forecasting, a range of forecasts from the various sources of information were developed and are illustrated in **Figure 5.1-2**.

Figure 5.1-2 George Massey Tunnel Replacement Bridge Range of Traffic Forecasts

The upper line, GMT (TL-RTM Untolled), shows modelled annual average daily volumes (AADT) for 2030 and 2045 using TransLink's RTM with the new bridge in place and no tolls being applied. This represents the highest potential future traffic volumes in the LAA. The lowest line, GMT (TL-RTM Tolled), shows modelled AADT for 2030 and 2045 using TransLink's RTM model with the new tolled bridge in place, using the Port Mann Bridge tolling framework. The variance in daily traffic volumes between the tolled and un-tolled scenarios is due to a change in travel patterns and driver behaviour in response to the implementation of tolls at the crossing. The majority of this difference applies to drivers who avoid crossing the river at all or divert to the Alex Fraser Bridge, primarily during off-peak periods and weekends. Only minor changes in traffic volumes at other crossings are anticipated with the implementation of tolls at the new bridge crossing. Limitations in the current version of TransLink's RTM do not permit exact estimates of travel pattern changes whether in terms of not crossing the river, diversion to an alternate crossing, or changing modes.

The GMT Forecast line, derived from an examination of traffic pattern changes at the new Port Mann Bridge – including time of day and day of week changes and an analysis of the availability of alternate routes using origin-destination data, as well as projected growth rates for auto and truck traffic at the replacement crossing for the Tunnel, shows AADT forecasts from the present to 2045 with the new tolled bridge in place and with adjustments to reflect current experience at the Port Mann Bridge. Specifically:

- **New Bridge Baseline Traffic Forecast** – First-year daily traffic with the new bridge is forecast to be 71,000, representing a 14 per cent drop from forecast volumes under continued Tunnel operation. This is consistent with the actual Port Mann Bridge experience, as well as with the analysis of the potential for existing Tunnel and AFB traffic to redistribute between the two crossings.
- **New Bridge Growth Forecast** – Future auto growth is forecast to average approximately 0.65 per cent annually – consistent with recent-year trends for Richmond and Delta traffic via the Tunnel and AFB, and at about half of RGS population and employment growth forecasts for south-of-Fraser municipalities. Future truck growth is forecast to average 1.5 per cent annually – consistent with recent-year truck growth trends at the Tunnel, and in line with RGS forecast population and employment growth (Ministry 2015b). Based on this growth, traffic demand at the new bridge is forecast to be 84,000 vehicles per day by 2045.

The GMT (SDG Independent) line shows AADT volumes based on independent forecasts developed by Steer Davies Gleave (SDG 2015) from the present to 2045 with the new bridge in place and a tolling regime matching the one at the Port Mann Bridge applied. The independent forecast indicates a slightly lower drop in opening-year daily traffic and a slightly different future growth rate when compared to the GMT Forecast line.

Traffic forecasts are used to support the assessments of atmospheric noise, local air quality and wildlife. These assessments measure With and Without the Project 10 years after implementation (or 2030 as a proxy, given best available modelled traffic information). Given the variability in the forecasting, and to ensure a conservative assessment for EA purposes, the upper range of forecast values (TL-RTM untolled, 2030 With the Project) were used as it represents the highest potential volume of traffic. These traffic assumptions support the assessments undertaken in **Section 4.8 Terrestrial Wildlife**, **Section 4.9 Air Quality** and **Section 4.10 Atmospheric Noise**.

The “TL-RTM tolled, 2045 With the Project” forecasts were used to describe trends in traffic within the RAA because they provide the best-available level of detail necessary for the required comparative analysis (see Regional Traffic Forecasts discussion below).

Traffic Forecasts for Roadway Design

Geometric design of roads, bridges, intersections, and interchanges requires current and forecast a.m. and p.m. design hourly volumes (DHVs), rather than AADT, to ensure safe and efficient traffic flows during peak traffic conditions. The DHVs that have been used to support the design of Project elements within the LAA are provided in **Appendix D**. In addition, the DHV forecasts and operational requirements were used to determine the number of lanes required for the bridge as described in **Section 1.3 Project Design and/or Alternative Means of Carrying out the Project**.

5.1.2.4.2 Regional Traffic Forecasts

The Metro Vancouver RGS and other regional and community planning initiatives forecast significant growth in population and employment within the RAA, as well as growth in travel demand for people and goods. To evaluate the potential influence of the Project on future regional traffic conditions, in the context of forecast growth associated with the RGS, region-wide vehicle kilometers travelled (VKT) and vehicle hours travelled (VHT) using TransLink’s RTM long-range forecasts to 2045 were examined. **Table 5.1-2** and **Table 5.1-3** show region-wide VKT and VHT for a regional morning peak hour (a.m.), and an afternoon peak hour (p.m.) for 2014, for 2045 without the Project, and for 2045 with the Project (tolled).

Table 5.1-2 Regional Vehicle Kilometers Travelled Using TransLink’s Regional Transportation Model (State 0)

| Hour | 2014 VKT (Current) | 2045 VKT (Without Project) | 2045 VKT (With Project and Tolled) |
|-------------------|-----------------------|-------------------------------|---------------------------------------|
| AM – 7:30 to 8:30 | 4,120,000 | 5,405,500 | 5,373,500 |
| PM – 4:30 to 5:30 | 4,565,000 | 5,956,500 | 5,910,300 |

The forecasts in **Table 5.1-2** indicate regional annual average rush hour VKT will increase over the next 30 years without the Project, as population, employment, and goods movement continue to grow. The Project, including tolled access across the new bridge, will result in lower VKT compared to a future without the Project in 2045.

Table 5.1-3 Regional Vehicle Hours Travelled Using TransLink’s Regional Transportation Model (State 0)

| Hour | 2014 VHT (Current) | 2045 VHT (Without Project) | 2045 VHT (With Project and Tolled) |
|-------------------|-----------------------|-------------------------------|---------------------------------------|
| AM – 7:30 to 8:30 | 81,900 | 120,500 | 120,400 |
| PM – 4:30 to 5:30 | 95,400 | 145,000 | 142,600 |

The forecasts in **Table 5.1-3** indicate that regional annual average rush hour VHT will increase over the next 30 years without the Project, as compared to current levels. The Project is not expected to change this, as there is virtually no change in forecast VHT when comparing with and without the Project in 2045.

Given the integrated nature of the regional road network, and the Ministry’s role in the operation of the network, assessment of potential effects of the Project on the operation of other nearby Fraser River crossings in the RAA has also been undertaken.

Current AADT volumes at nearby crossings and the highest potential 2045 future traffic forecasts without the Project and with the Project (tolled) are provided on **Table 5.1-4**. The 2045 forecasts derived from TranLink’s RTM show an increase in AADT at the nearby Fraser River crossings without the Project, when compared to current levels. When comparing with and without the Project for the Fraser River North Arm crossings, Knight Street Bridge, Arthur Laing Bridge, and Oak Street Bridge, results show a small decrease in traffic with the Project. For the AFB, however, results show a 17 per cent increase in daily traffic with the Project when compared to without the Project, primarily because of off-peak diversion from the tolled facility to the untolled facility.

Table 5.1-4 Two-way Annual Average and Daily Traffic Volumes on Adjacent Fraser River Crossings, With and Without the Project Using TransLink’s Regional Transportation Model (State 0)

| Crossing | 2014-2015 | 2045 | |
|----------------------|-----------|-----------------|-------------------------|
| | Measured | Without Project | With Project and Tolled |
| Alex Fraser Bridge | 107,000 | 120,000 | 140,000 |
| Knight Street Bridge | 92,000 | 94,000 | 93,000 |
| Arthur Laing Bridge | 76,000 | 90,000 | 91,000 |
| Oak Street Bridge | 80,000 | 87,000 | 85,000 |
| Knight + Laing + Oak | 248,000 | 271,000 | 269,000 |

Oak Street Bridge

Although Oak Street Bridge is outside of the LAA, during the Pre-application public comment period, some members of the public and the Technical Working Group asked questions regarding current and future traffic conditions at the Oak Street Bridge. As a result, the Ministry conducted a detailed analysis on current and future traffic conditions at the Oak Street Bridge. The findings of that analysis are presented below.

Figure 5.1-3 shows measured traffic at the Oak Street Bridge from 2005 to 2014 for Annual Average Weekday Traffic (AAWDT), AADT, and Annual Average Weekend Traffic (AAWET). The figure shows that since commuters have adjusted to the introduction of the Canada Line, vehicle volumes on the Oak Street Bridge have been declining year over year, particularly on weekdays. After a drop in 2011, weekend volumes have plateaued at slightly lower than 2010 volumes.

Figure 5.1-3 Oak Street Bridge – Daily Traffic Volumes, 2006 to 2014

Hourly traffic patterns at the Oak Street Bridge were also examined to consider potential effects on northbound rush-hour traffic flow conditions. **Figure 5.1-4** shows vehicle volumes by time of day for an average September weekday when traffic volumes are traditionally high. The figure indicates that Oak Street Bridge traffic volumes during rush-hour periods – when congestion is of primary concern – have dropped between 2010 and 2015, since the introduction of the Canada Line.

Notwithstanding decreases in traffic volumes in recent years, the intersection of Oak Street and 70th Avenue at the north end of the Oak Street Bridge in Vancouver is likely to remain congested for northbound a.m. rush hour traffic in the future due to the signal lights at this location. During Project operation, some northbound a.m. south-of-Fraser commuters may change their preferred travel time to take advantage of the time savings and reliability that the new bridge provides. This could make queue lengths at Oak Street a little longer during the busiest part of rush hour. However, the transit improvements included in the Project, in conjunction with tolling, will support and enable a mode shift towards greater use of transit in the Highway 99 corridor, including the Canada Line, and away from single occupancy vehicle-based commuting trips across the Oak Street Bridge.

Figure 5.1-4 Oak Street Bridge – September 2010 and 2015 Northbound Weekday Vehicle Volumes, by Hour

5.1.3 Potential Effects

This section provides a summary of potential Project-related effects on traffic as a result of construction and operation of the Project. It also describes the methodology used to assess potential Project-related effects.

5.1.3.1 Project Interactions

An overview of the potential effects of Project interactions on traffic within the LAA is provided in **Appendix A**, and is summarized below.

Highway upgrades, reconstruction of interchanges, and new bridge construction will necessitate temporary detours, temporary lane closures, and changes to the existing counter-flow system, which will affect traffic. Additionally, construction vehicles will temporarily add incremental growth in traffic to existing Highway 99 traffic volumes.

During Project operation, traffic volumes, patterns, mode share, and travel choices are expected to change as a result of the reconfigured Highway 99, new interchanges, and the new bridge. Maintenance activities associated with Project operation are anticipated to have negligible interactions with traffic, and are not assessed further.

5.1.3.2 Potential Effects

The following section identifies potential Project-related effects on traffic as a result of Project activities during the construction and operational phases of the Project.

5.1.3.2.1 Construction

Based on the Ministry's knowledge of road construction in urban areas, including recently completed work on the Port Mann/Highway 1 improvements, the Project has been developed with the following key traffic management elements:

- Full access for emergency and first responders will be maintained at all times.
- The Highway 99 corridor and connecting interchanges will remain operational to current levels of service during the day and early evenings. The counter-flow system will be maintained during weekdays as per the current schedule.
- Transit service will be maintained.
- Access to existing roads, driveways, bus stops, and cycling and pedestrian networks will be maintained.
- Nighttime lane closures may occur, as is currently permitted for road maintenance, but at least one lane of traffic in each direction will be maintained. Special restrictions will apply during holidays or special events.
- Temporary relocations and detours of existing highway ramps, roads, driveways, bus stops, and cycling and pedestrian networks will be permitted.
- Limited full closures of the highway will be permitted for unique circumstances such as bridge deck lifts directly over the Tunnel and approaches. Criteria for the timing and duration of full closures will be set when adjacent roads such as Highway 91 are able to accommodate additional traffic.

In concert with the establishment of lower construction speed zones, traffic management strategies, including safety requirements for travellers and workers, as well as incident management measures to assure effective responses to emergencies will be employed during the construction period. As a result of these measures, no variance in the number of incidents within the Project corridor, relative to baseline conditions, is anticipated and no residual effects pertaining to traffic safety during construction are expected. The following potential effects have been identified:

- Increased travel times along the Highway 99 corridor resulting from implementation of reduced speed limits through active construction zones
- Increased travel times and distance travelled resulting from detour arrangements or limited Highway closures for specialized construction activities. Additional travel time and travel distance will vary dependent on the location and duration of the specific works. For example, a temporary detour/diversion at an interchange would require minimal delay, while a closure of the Tunnel for overhead works would necessitate a longer detour via an alternate crossing such as AFB.
- Increased traffic volumes and potential minor interruptions as new construction-related traffic interacts with regular flows.
- Temporary changes to transit routes, schedules, and bus stop facilities, developed in conjunction with TransLink.
- Temporary changes to local cycling and pedestrian patterns during construction of interchanges and underpasses.

The contractor will be required to maintain counter-flow operations during peak times. For peak-period traffic, current throughput rates will be maintained so that impacts on travel times and congestion-related delays will be minimal. For off-peak traffic, the lowered speeds through active construction zones are expected to have a minor impact on travel times, in the range of a one to two minute increase over a construction speed zone of approximately 5km.

While it is anticipated that traffic impacts during construction will generally be confined to minor delays within the Project corridor resulting from reduced construction speed limits and periodic diversions around active works at interchanges and underpasses, infrequent full highway closures are expected for specialized work such as bridge deck lifts over the Tunnel and approaches. Such closures would be scheduled for overnight periods and/or weekends to minimize traffic impacts. In these circumstances, traffic will be detoured via alternate routes, and additional travel time will be incurred by some Tunnel traffic. Traffic between South Surrey and Vancouver will not experience significant additional travel time to detour to Highway 91/AFB. However, traffic between Delta and Richmond will typically experience (depending on trip origin and destination) an additional travel time of 6 to 12 minutes, and additional travel distance of 9 to 18 kilometers during overnight closures.

Operation

The following steps were followed in assessing potential Project-related changes in traffic during operations:

- Consider traffic volumes, patterns, mode share, VKTs, and VHTs for three scenarios – existing, future without the Project, and future with the Project.
- Use the estimated future values to predict the incremental changes with and without the Project within the LAA.

During Project operation, transit, cycling and pedestrian infrastructure improvements, roadway upgrades, new interchanges, and the new toll bridge will align with and support current regional planning initiatives as detailed in **Section 5.3.3.2 – Project Effects** (Consistency with Land Use Plans and Designations), and highlighted below:

- Relieve congestion and improve reliability; for example, the average commuter will save 25 to 35 minutes per day when the new bridge opens in 2022. These benefits have been estimated through an analysis of:
 - current traffic throughputs at the Tunnel, by time of day and day of week – as measured through traffic counters at the Tunnel;
 - current travel times and congestion-related delay patterns, including variability – as measured by the Ministry’s Automatic Traveller Information System;
 - historic population growth patterns in relevant communities – based on census data;
 - historic traffic patterns at the Tunnel and other Fraser River crossings – based on Ministry, TransLink and municipal counters and screenline surveys;
 - future population and employment forecasts – as issued by Metro Vancouver; and,
 - future traffic volume and patterns for the new bridge - based on combining the above-mentioned sources.
- Support improved regional goods movement; for example, improving travel times and reliability will help improve scheduling and operational efficiency, and the additional capacity will better accommodate slower and merging truck traffic.
- Improve safety for all road users with a forecast decrease in crash frequencies of 35 per cent, and facilitate quicker, more reliable first responder access.
- Support provincial and regional strategies to encourage mode shift to transit and carpooling by providing continuous, dedicated transit/HOV lanes in both directions along Highway 99 between Surrey and Vancouver. Traffic model analysis based on the application of TransLink’s RTM indicates that the transit mode share across the future bridge increases in the range of 5-10% in the 2045 planning horizon, as compared to without the Project.

- Provide new active transportation options including cycling and walking to further encourage a shift away from automobile travel and support reduced GHG emissions and improved regional health.
- Reduce congestion and support more fuel-efficient travel speeds to help lower per-trip fuel consumption and GHG emissions.
- Tolling will assist in managing congestion, moderate future growth in traffic, and support more favourable mode-share choices.

These regional and local traffic benefits also enable important social and community goals and objectives of local and regional land use plans including community health and livability. Benefits of the Project are further discussed in the Business Case (MOTI 2015a) for the Project

The Project was developed to help mitigate current and anticipated traffic challenges that are resulting in adverse effects on environmental, economic, social, and health values. In this context, effects of the Project during operation are expected to be positive, and post-construction no adverse effects are anticipated. **Section 5.1.7** outlines specific traffic-related measurements that will be carried out during operation to confirm that Project performance objectives have been achieved.

5.1.4 Mitigation Measures

Mitigation measures developed to avoid or reduce potential Project-related adverse effects on traffic during construction are described in this section. A hierarchical approach was used based on avoidance of potential effects first, followed by minimization or reduction of unavoidable effects to identify strategies for mitigating potential Project-related effects.

5.1.4.1 Avoidance

As noted in **Section 5.1.3.2**, traffic management activities will meet performance requirements and maintain current highway traffic flow conditions during designated periods and events.

5.1.4.2 Minimization

Measures to minimize potential Project-related effects on traffic during Project construction, as outlined below, were identified based on mitigation applied and shown to be effective during the delivery of other major transportation developments undertaken by the Ministry including the Sea to Sky Highway Improvement Project, the Port Mann/Highway 1 Project, and the South Fraser Perimeter Road Project.

Construction

The Project will be a major multi-year construction project, which will occur on one of the busiest stretches of highway in the Lower Mainland. Careful traffic management is required to mitigate the potential effects on current traffic operations during construction work, and avoid or minimize construction-related traffic congestion, disruptions, and delays.

A detailed Construction Traffic Management Plan (CTMP) will be developed to identify and address traffic management risks and approaches for managing traffic and communicating with stakeholders and the public during the construction period. An outline of the CTMP is presented in **Section 12.0 Management Plans**. This plan will be reviewed with key stakeholders, including affected municipalities, emergency responders, and property owners and users adjacent to the Project, prior to the start of construction and following development of the final Project design and construction plan.

Key elements of the CTMP include:

- Traffic management strategies, including access routes to ensure continued movement of traffic on the Highway 99 corridor and initiatives to minimize disruption and maximize predictability for Highway 99 travellers, cycling and pedestrian network users, and nearby residents and businesses
- Safety requirements to maintain a safe corridor at all times for travellers and workers
- Communications activities in support of implementation of the CTMP
- Incident management and response measures

The CTMP will be required to meet performance objectives set by the Ministry, including those that relate to maintenance of access to existing developments and maximum wait times or delays in traffic flow.

For all construction activities that affect traffic operations, the Contractor will be required to provide a detailed description on how performance requirements for traffic management during construction will be addressed and complied with. These requirements are under development and may include, but are not limited to requirements for:

- Permitted lane closure/reduction windows
- Local detours and lane shifts
- Traffic control devices, such as construction and advisory signs, project signs and changeable message signs
- Temporary roadside barrier requirements
- Drop offs (abrupt changes in roadway elevation)

- Temporary Pavement Markings
- Location and storage of materials and equipment
- Speed Limits and Safe Passage through construction sites
- Permissible stoppages

Incident management and incident response measures will be developed as part of the CTMP to facilitate appropriate incident response and move traffic safely and expeditiously through or around the incident. The CTMP will address passage of emergency vehicles, assistance to emergency response personnel, motor vehicle crashes, emergency road repairs, disabled vehicles and debris on the road as well as provide information on the Contractor's communication system with emergency providers.

The CTMP will follow the Ministry's Traffic Management Guidelines for Work on Roads (B.C. MOTI 2001), Traffic Control Manual (B.C. MOTI 1999), and Standard Traffic Signs and Pavement Markings Manual (Ministry 2000) for temporary lane markings¹.

Communications aspects of the CTMP are of critical importance as they represent the interface between traffic management and the travelling public. Communications considerations to be addressed in the CTMP include information regarding traffic control plans, road signs and sign locations, and detour logistics. In addition, the communications sections of the CTMP will identify:

- Measures to be used to inform stakeholders of traffic management activities during construction
- Protocols to be followed in the event of an emergency
- Key stakeholders with an interest in the development and implementation of the CTMP including Ministry Operations, the contractor, municipalities, schools, emergency responders, marine users, and special traffic generators

The public will be notified of potential impacts of construction activities on traffic via a number of methods such as:

- Notices placed in the print media, Internet web pages and/or provided to the radio and television media
- Project signs, including changeable message signs
- The Ministry's online traffic information and trip planning tool (Drive BC0

¹ The documents listed here are currently being reviewed and may be updated. The CTMP will follow the updated versions as applicable.

- Direct communications, such as by mail-outs, to affected businesses and homeowners
- Brochures and other printed notices
- Public information telephone line

The Plan will take into account resident commuter travel and travel times, and commuting requirements of shift workers, local businesses and events.

Operation

As noted in **Section 5.1.1**, the rationale for the Project and key Project objectives are to address existing and anticipated traffic challenges in the Highway 99 corridor. As shown in **Section 5.1.2.4**, the Project will improve performance of the Highway 99 corridor with respect to safety, travel time and reliability, and mode share.

With respect to mitigation for temporary traffic management that may occur during the operation phase, the Project will follow the Ministry's traffic management guidelines for work on roads (Ministry 2001), Traffic Control Manual (Ministry 1999, Interim 2015), and Standard Traffic Signs and Pavement Markings Manual (Ministry 2000) for temporary lane markings.

Consistent with the Ministry's approach to Intelligent Transportation Systems (ITS) as a means to integrate communication and information technology to better manage and operate B.C.'s transportation system, the Project will include the following components to support improved operational performance on the Highway:

- Additional traffic cameras, linked to the Ministry's Drive BC online traffic information and trip planning tool
- Traffic sensors, cameras, and software to assist in providing a coordinated response to traffic accidents
- Dynamic message signs linked to traveller information systems to report delays and advise of alternate routes.

5.1.5 Residual Effects

Implementing the mitigation measures described in Section 5.1.5 will minimize potential Project-related changes on traffic during construction, although temporary, minor residual effects will be incurred.

As noted in Section 5.1.1, the rationale for the Project and key Project objectives are to address existing and anticipated traffic challenges in the Highway 99 corridor. The integration of smart transportation technologies into the Project will provide measures to manage traffic challenges

along the Highway 99 corridor and the regional road network. Additionally, integrating tolling into the Project provides a mechanism for managing future traffic demand.

5.1.5.1 Characterization of Residual Effects

Based on the Ministry's experience in managing traffic during the construction of major highway projects, the effects on traffic and the management of traffic during highway construction are well-understood. Temporary effects related to construction activities include:

- Effect #1: Change in traffic volume
 - Minor interruptions as construction-related traffic interacts with regular flows.
- Effect #2: Change in mode share
 - Temporary changes to transit routes and bus stops.
- Effect #3: Change in travel time and reliability
 - Marginal increases in off-peak travel times resulting from reduced speed limits through active construction zones.
 - Increased travel times and distance travelled during infrequent full highway closures for specialized construction activities, approximating an additional 6 to 12 minutes and 9 to 18 km for travellers between Delta and Richmond, depending on trip origin and destination

The above construction-related residual effects on traffic are characterized with respect to the direction, magnitude, extent, duration, frequency, reversibility, and likelihood of each anticipated effect. Definitions for ratings applied to residual effects criteria, developed with specific reference to Traffic are presented in **Table 5.1-5**.

Table 5.1-5 Criteria Used to Characterize Residual Effects on Traffic

| Criteria | Description | Definition of Rating | |
|-----------|--|----------------------|--|
| Direction | Overall nature of the residual effect | Adverse | Negative effect as a result of the Project. |
| | | Positive | Beneficial effect as a result of the Project. |
| | | Neutral | Neutral effect as a result of the Project. |
| Magnitude | Intensity of the effect relative to natural or baseline conditions | Negligible | No measurable change from baseline conditions. |
| | | Low | A measurable change of less than 5 minutes additional travel time relative to baseline conditions. |
| | | Moderate | A measurable change of 5-20 minutes additional travel time relative to baseline conditions. |
| | | High | A measurable change of greater than 20 minutes additional travel time relative to baseline conditions. |
| Extent | Geographic extent / distribution of the residual effect | Site | Effect is restricted to the immediate Project alignment. |
| | | Local | Effect is restricted to the LAA and connecting Highways and cross streets in Richmond, Delta & Surrey |
| | | Regional | Effect occurs beyond the LAA and connecting Highways and cross streets. |
| Duration | Length of time over which the residual effect is expected to persist | Transient term | Effect persists for less than 24 hours. |
| | | Short term | Effect persists for 24 - 72 hours. |
| | | Moderate term | Effect persists throughout Project construction. |
| | | Long term | Effect is permanent. |

| Criteria | Description | Definition of Rating | |
|---------------|---|----------------------|--|
| Frequency | Nature of the occurrence of the residual effect | Infrequent | Effect occurs intermittently during Project construction (e.g. full-closures for specialized activities) |
| | | Frequent | Effect occurs frequently during Project construction |
| | | Continuous | Effect occurs continuously during Project construction |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after the disturbance has ceased (or after a period of time after the disturbance has ceased) | Reversible | Baseline conditions will be restored or improved after disturbance has ceased. |
| | | Irreversible | Baseline conditions will not be restored after disturbance has ceased. |
| | | Change | Effect may fluctuate between positive and adverse for the duration of the disturbance. |
| Likelihood | Likelihood that the residual effect may occur | Low | Likelihood of residual effect is less than 25%. |
| | | Moderate | Likelihood of residual effect is between 25% and 75%. |
| | | High | Likelihood of residual effect is greater than 75%. |

Residual Effect #1: Temporary change in traffic volume during construction

During construction, temporary effects to traffic may be incurred due to incremental construction-related vehicles accessing/egressing the Project area and interacting with regular traffic flows.

Highway upgrades, reconstruction of interchanges and new bridge construction will introduce additional vehicles and equipment to the corridor. Traffic impacts associated with this incremental volume is considered low in magnitude as all construction activities that affect traffic will be conducted in accordance with the CEMP which includes measures to minimize disruption and delays associated with changes in traffic.

Effects will be of a temporary duration, occurring only during the construction phase. Post-construction, there are no adverse effects to traffic as the additional general capacity as well as the dedicated transit/HoV lanes will accommodate traffic volumes associated with future population and employment growth. A summary of criteria ratings for traffic volume effects during construction is provided in **Table 5.1-6**.

Table 5.1-6 Criteria Ratings for Construction-related Change in Traffic Volume

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|--|
| Direction | Adverse | Minor increase in traffic volumes and potential minor interruptions are expected as new construction-related traffic interacts with regular flows. |
| Magnitude | Low | Change will be within the range of natural variability and travel time impacts will be low. |
| Extent | Local | Spatial extent is local - specific to the Project alignment, and connecting Highways and cross streets. |
| Duration | Moderate Term | Minor effects will occur throughout the construction period, |
| Frequency | Frequent | Frequent occurrence for minor effects related to introduction of construction-related traffic. |
| Reversibility | Reversible | Effects eliminated on completion of construction. |
| Likelihood | High | Temporary construction-related traffic effects unavoidable. Mitigation will minimize impacts to the extent possible. |

Residual Effect #2: Temporary influence of construction on mode share

Temporary changes to transit routes, schedules and bus stops during construction will affect transit users. Such changes will occur at different locations, at different times and for different durations depending on the specific construction activity being undertaken. In particular, it is anticipated that construction of interchanges will necessitate minor changes to transit schedules and travel times due to temporary alignment shifts, diversions and/or detours at these locations. All changes affecting transit will be developed in conjunction with TransLink.

During construction, effects associated with changes to transit schedules and transit/HoV routes are generally low in magnitude, comprising minor increases in travel times resulting from reduced construction speed limits in construction zones and periodic diversions around active work sites. A moderate magnitude is expected during infrequent full-closures for specialized activities necessitating a detour via Highway 91. Effects will be of temporary duration, occurring only during the construction phase and are not anticipated to affect transit ridership levels or mode share for high-occupancy vehicles during the construction period.

Project improvements support strategies to encourage mode shift to transit and carpooling through the provision of dedicated transit/HoV lanes between Bridgeport Road in Richmond and Highway 91 in Delta. Transit-only ramps at Bridgeport Road as well as integrated transit stops at Highway 17A and Steveston Highway will further improve the accessibility, efficiency, reliability and attractiveness of transit resulting in increased transit mode share on completion of the Project. Further, tolling will assist in moderating future growth in traffic and support more favourable mode-share choices. A summary of criteria ratings for mode share is provided in **Table 5.1-7**.

Table 5.1-7 Criteria Ratings for Construction-related Change in Mode Share

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|--|
| Direction | Adverse | Expected temporary changes to bus routes and schedules will affect transit users. |
| Magnitude | Low | During construction, transit users may temporarily incur some minor increase in travel time relative to baseline conditions. |
| Extent | Local | Effects will be limited to transit users in the Project area. |
| Duration | Moderate Term | Minor, temporary effects anticipated throughout construction period at different locations and at different times dependent on prevailing construction activities. |
| Frequency | Frequent | Effect is expected to occur frequently, at different times and different locations, throughout the construction period. |
| Reversibility | Reversible | Long-term improvements to transit and HoV accessibility, efficiency, reliability and resultant mode share as a result of the Project. |
| Likelihood | High | Refinements to transit routes/schedules anticipated in concert with key construction activities such as interchanges. |

Residual Effect #3: Temporary change in travel time and reliability during construction

During construction, current levels of service will be maintained on Highway 99 and connecting interchanges during the day and early evenings. The counter-flow system will be maintained during weekdays as per the existing schedule. Nighttime lane closures will be permitted, but at least one lane of traffic will be maintained in each direction and limited full-closures of the highway will be permitted for unique circumstances such as bridge deck lifts over the Tunnel and approaches. Reduced speed limits will also be in effect through active construction zones.

Travel time and reliability effects will be incurred during Project construction. As current levels of service will be maintained during peak periods and daytimes, the magnitude of travel time and reliability effects is considered to be low. A moderate magnitude is anticipated during infrequent full-closures requiring additional travel time via a detour to Highway 91.

Effects to travel time and reliability are moderate in duration, occurring throughout the construction phase. Impacts are minor in relation to effects related to reduced construction speed zones and periodic diversions around active works at interchanges and underpasses. Infrequent highway closures for specialized activities will cause additional travel time impacts during these short-duration events, in the range of 6-12 minutes for nighttime travelers between Delta and Richmond, depending on origin and destination.

A key objective of the Project is to address congestion and improve travel time and reliability. Post-construction, both travel times and reliability will be greatly improved and there are no residual effects during operations. A summary of criteria ratings for travel time and reliability effects during construction is provided in **Table 5.1-8**.

Table 5.1-8 Criteria Ratings for Construction-related Change in Travel Time and Reliability

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|------------------------|---|
| Direction | Adverse | Temporary, minor increases in travel times are expected due to reduced speed limits through active construction zones and detours or closures for specialized activities. |
| Magnitude | Low to Moderate | Low magnitude of effect for temporary diversions/detours on Project corridor and low-moderate magnitude for infrequent full-closures necessitating detour via Highway 91. |
| Extent | Local | Effect temporary and limited to LAA and connecting Highways and cross streets. |
| Duration | Short to Moderate Term | Effect is short term during infrequent highway closures and moderate term for temporary effects related to travel through construction speed zones. |
| Frequency | Frequent | Effect is expected to occur frequently, at different times and different locations, throughout the construction period. |
| Reversibility | Reversible | Long-term travel time and reliability improvements are expected as a result of the Project. |
| Likelihood | High | Temporary, construction-related effects unavoidable. Mitigation will minimize effects to the extent possible. |

5.1.6 Cumulative Effects

The combination of Project-related changes, and changes from other certain and reasonably foreseeable projects and activities, as listed in **Section 3.10.1 Identifying Past, Present or Reasonably Foreseeable Projects and/or Activities**, comprise the total cumulative changes in traffic. This includes TransLink's proposed Pattullo Bridge replacement, with a planned construction period between 2019 and 2023, which overlaps temporally with the Project. As the planned Pattullo replacement is a new structure, upstream of the existing bridge, traffic will be maintained on the current alignment throughout the construction period. Accordingly, there are no residual effects anticipated from the Pattullo replacement that could interact with residual construction-related effects of the Project on traffic.

No other past, present or reasonably foreseeable projects or activities with traffic-related residual effects that could overlap spatially or temporally with those of the Project and result in cumulative effects have been identified.

5.1.7 Follow-up Strategy

During construction, the TCMP will include traffic monitoring to ensure prescribed levels of service for travellers are maintained. Quality Control and auditing processes will be implemented to measure performance, ensure compliance, and identify any areas for improvement.

During operation, traffic monitoring for the Project will follow the same processes as other major highways in the Lower Mainland. In addition, specific monitoring of travel times, traffic incidents, transit, cycling and pedestrian usage, and goods movement surveys will be carried out to verify the Project performance objectives related to traffic.

APPENDIX A

Overview of Potential Project Interactions with Traffic

Table 1 Overview of Potential Project Interactions with Traffic

| Project Phase/Component | Interaction Ranking | Project Works and Activities that Interact with Traffic | Nature of Potential Interaction |
|--|---------------------|--|---|
| Pre-Construction / Site Preparation | | | |
| Pre-Construction / Site Preparation | No Interaction | <ul style="list-style-type: none"> • Surveying • Acquiring property for the Project | N/A |
| | No Effect | <ul style="list-style-type: none"> • N/A | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Clearing and grubbing within the existing Highway 99 ROW • Restoration of Green Slough to its original location • Installing temporary drainage structures and diversions • Installing temporary bridges and barging facilities • Conducting additional site investigations (i.e., a geotechnical drilling program) • Installing temporary roads, laydown areas, and site offices • Relocating utilities • Preloading for embankment and highway construction | <p>Nature of interaction: Works and activities adjacent to Highway 99 that could interact with highway operation.</p> <p>Rationale: May require temporary changes in highway operation including detours of existing traffic.</p> |

| Project Phase/Component | Interaction Ranking | Project Works and Activities that Interact with Traffic | Nature of Potential Interaction |
|--|---------------------|--|--|
| Construction | | | |
| New bridge including approaches and ramp connections | No Interaction | <ul style="list-style-type: none"> • N/A | N/A |
| | No Effect | <ul style="list-style-type: none"> • N/A | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Installing upland piers, including pile installation • Installing drainage structures/settling ponds • Ground improvements associated with new bridge piers • Installing piers adjacent to Deas Slough and Green Slough, including pile installation • Hoisting pre-assembled deck segments from barges in the river or land-based transport system • Constructing approach spans (concrete deck slab on steel or concrete girder) • Constructing bridge towers and installing support cables using land-based equipment • Installing retaining walls | <p>Nature of interaction: Works and activities adjacent to or above Highway 99 that could interact with highway traffic.</p> <p>Rationale: May require temporary changes in highway operation including detours of existing traffic.</p> |

| Project Phase/Component | Interaction Ranking | Project Works and Activities that Interact with Traffic | Nature of Potential Interaction |
|---|---------------------|---|--|
| Highway 99 improvements, including interchange upgrades | No Interaction | N/A | N/A |
| | No Effect | N/A | N/A |
| | Potential Effect | <ul style="list-style-type: none"> • Replacement of interchanges at Westminster Highway, Steveston Highway and Highway 17A • Replacement of over/underpasses at Cambie Road, Shell Road, Highway 91 Westbound Ramp, Blundell Road, Ladner Trunk Road and 112th Street • Highway widening from Bridgeport in Richmond to Highway 91 in Delta including construction of embankments, placing and compacting fill for road base, establishing improved drainage and paving | <p>Nature of interaction: Works and activities adjacent to Highway 99 that could interact with highway traffic.</p> <p>Rationale: May require temporary changes in highway operation, including temporary detours.</p> |

1. INTRODUCTION

The purpose of this report is to provide an overview of the traffic information collected and the assessment undertaken to support the development of the George Massey Tunnel Replacement Project. It also serves as a technical reference document through the inclusion of appendices with facts, figures, and records of source documentation.

2. HISTORICAL TRAFFIC

2.1. PROBLEM IDENTIFICATION

Both the Tunnel and the parallel Alex Fraser Bridge (AFB) serve traffic demand between Surrey/Delta and Vancouver/Richmond. Combined traffic growth at these two crossings has averaged 0.64 per cent per year between 2003 and 2013. The AFB has absorbed almost all of this growth, because of the lack of available capacity at the Tunnel (see Figure 1 below).

Figure 1: Annual Average Daily Traffic (AADT) – GMT vs AFB – 1987 to 2015

Source: Ministry of Transportation Traffic Data program – Note: 2015 data includes January to June

The four-lane Tunnel operates with a counter-flow system during the rush hour period, with only one lane open in the non-peak direction. Traffic volumes in the non-peak direction have grown steadily over the past 15 years. Traffic volumes outside of the rush hour period have also grown to the point where the Tunnel is close to capacity throughout the day as shown in Figure 2 below.

Figure 2: Average Hourly Two-Way Traffic Profile – George Massey Tunnel

Source (Figure 2 and Figure 3): TransLink's 2011 and 1999 Metro Vancouver Regional Screenline Survey

By comparison, traffic growth at AFB has occurred at almost all times of the day, as shown in Figure 3. AFB traffic has grown annually at 1.51 per cent (2003-2013).

Figure 3: Average Hourly Two-Way Traffic Profile – Alex Fraser Bridge

2.2. HISTORICAL TRAFFIC DATA SOURCES

The following is a list of historical traffic data sources that the Project Team used to supplement the rigorous traffic data collection program undertaken as part of Project planning:

- Permanent Count Stations (MoTI, municipal, etc.)
- TransLink Metro Vancouver Regional Screenline Surveys
- Spring 2012 Traffic Counts (Bunt and Associates)
- Cascade Gateway Data Warehouse USA / CDN Border Crossing Data (2006-2015)
- Traffic Data provided by municipalities
- Signal Data (MoTI)

Refer to APPENDIX A: HISTORICAL TRAFFIC DATA for details.

3. CURRENT TRAFFIC

3.1. DATA COLLECTION SOURCES

A traffic data collection program was implemented in 2013 to study traffic patterns at the Tunnel, along the Highway 99 corridor, and other parts of the region including Highway 91 and major routes connecting the two crossings. An expanded program was conducted in 2014 to confirm 2013 measurements and also assess the effects of the newly opened South Fraser Perimeter Road (SFPR). The following is a complete list of current traffic data collection methods:

- Permanent Count Stations
- Short Count Stations
- Tube Count Surveys
- Manual Count Surveys
- Vehicle Classification Surveys
- Vehicle Occupancy Surveys
- Origin-Destination (OD) Surveys
- Travel Time Surveys
- Queue Length Surveys
- Aerial Photograph Surveys
- Safety Assessment Surveys
- ICBC Collision Data
- MoTI Collision Information System (CIS) Data
- Traffic Signal Data Collection
- Bike Shuttle Data
- Transit Passenger Surveys

The following is a list of reports created from the data collection program:

- GMTRP – Traffic Data Collection Report – Fall 2013
- GMTRP – Traffic Data Collection Report – Spring 2014
- GMTRP – Traffic Data Collection Report – Summer 2014
- GMTRP – Traffic Data Collection Report – Fall 2014
- GMTRP – Analysis of OD Survey Data – Fall 2013
- GMTRP – Analysis of OD Survey Data – Fall 2014
- GMTRP – Collision Data Analysis – 2014

The Project Team continues to collect and analyze traffic data to confirm trends identified and to validate model results.

Refer to APPENDIX B: CURRENT TRAFFIC DATA for details.

3.2. GENERAL TRAFFIC

With vehicle demand at the Tunnel exceeding capacity, it is important to examine mode distribution. Figures 4 to 7 below illustrate mode distribution by vehicle type and user type. In the morning peak hour, 16% of Highway 99 travellers use HOV and 17% use buses. In the afternoon peak hour, 25% of Highway 99 travellers use HOV and 15% use buses.

Figures 4 and 5: General traffic mode percentages for vehicles and passengers (AM peak hour).

Figures 6 and 7: General traffic mode percentages for vehicles and passengers (PM peak hour).

Figures 1 to 3 illustrate that (1) the Tunnel has exceeded capacity, (2) there is no longer a viable alternative route for Tunnel users since AFB is now also congested at peak periods. Figures 4 to 7 illustrate that (3) Tunnel users already make effective use of efficient transportation modes (HOV and transit).

Refer to APPENDIX C: GENERAL TRAFFIC FACTS for details.

3.3. TRUCK TRAFFIC

Highway 99 and 91 are key components of the regional truck transportation network that supports local, provincial, and international trade. During the work week, 7000 trucks per day use the Tunnel, while 9000 trucks per day use the AFB.

Table 8 in Appendix D provides a regional context, by summarizing truck traffic volumes (counted from 7:00 to 17:30) at major South of Fraser crossings. Combined truck traffic on these crossings has increased 9.7 per cent over the past six years (2008 to 2014).

Table 9 provides further detail regarding GMT and AFB truck traffic. Table 10 provides further detail on the types and volumes of truck traffic at the Tunnel.

It is important to note that more than 50 per cent of truck traffic crosses the Fraser River at GMT and AFB during the midday. This is due in part to heavy congestion at these crossings during peak periods. Since the midday period at these crossings is becoming increasingly congested, additional capacity across the Fraser River, particularly the South Arm, to better connect East Richmond port and industrial lands, will support planned growth in local, provincial, and international trade. This additional capacity will also provide more efficient and reliable travel times beyond the midday period.

Refer to APPENDIX D: TRUCK TRAFFIC FACTS for details.

3.4. TRANSIT

During the morning rush hour approximately 60 per cent of trips to downtown Vancouver by residents of South Delta and South Surrey are made by transit (2011 TransLink Trip Diary).

The Tunnel has the highest number of buses crossing the Fraser daily. Nine northbound TransLink bus routes use the Tunnel during the morning rush period. This equates to a bus every two to three minutes (see Table 15 in Appendix E). While northbound morning rush period buses comprise only one per cent of traffic, they carry approximately 17 per cent of all Tunnel travellers.

On an average weekday, 559 buses carry 10,535 passengers through the Tunnel (see Table 10 in Appendix E). Table 13 in Appendix E contains a detailed breakdown of vehicle and passenger mode share through the Tunnel; the table splits the data by direction and period. Of note, more than 40 per cent of travellers through the Tunnel use HOV and transit; clearly indicating the importance of these options for many Highway 99 corridor users. Since these options have available capacity, it is clear that they are not a viable option for some travellers.

Refer to APPENDIX E: TRANSIT FACTS for details.

3.5. CYCLING & PEDESTRIAN TRAFFIC

Currently, cyclists and pedestrians are not permitted to use the Tunnel for safety reasons. In the absence of a viable alternate route, the Ministry operates a year-round free shuttle service through the Tunnel. In 2014 the shuttle transported an average of 910 people per month. Demand is higher in the summer, but averages 30 people per day over the year. The shuttle service does not operate on weekends during the winter months. The new bridge will include a multi-use pathway for cyclists and pedestrians, eliminating the need for the shuttle service.

Refer to APPENDIX F: CYCLING & PEDESTRIAN FACTS for details.

3.6. TOURISM

An important additional consideration is that Highway 99 carries a significant share of British Columbia's tourism traffic to destinations such as BC Ferries' Tsawwassen Terminal, the Vancouver International Airport, Whistler, the Canada–U.S. border, and Port Metro Vancouver's cruise ship terminals. For northbound afternoon traffic, delays are highest in July and August, reflecting the increase in tourism activity during these months. For example, in August 2014 the typical northbound weekday delays were 30 minutes, significantly higher than at other times of the year (refer to Figure 14 below).

3.7. ORIGIN – DESTINATION (OD)

After the Tunnel opened in 1959 it rapidly became a key commuter route to Vancouver for South of the Fraser residents. Commuter traffic to Vancouver accounts for only 40 per cent of the total traffic through the Tunnel, while almost 60 per cent of daily trips are between Richmond and communities south of the Fraser. Figures 8 and 9 illustrate daily origin – destination pairs for vehicles travelling through the Tunnel

on a typical weekday.

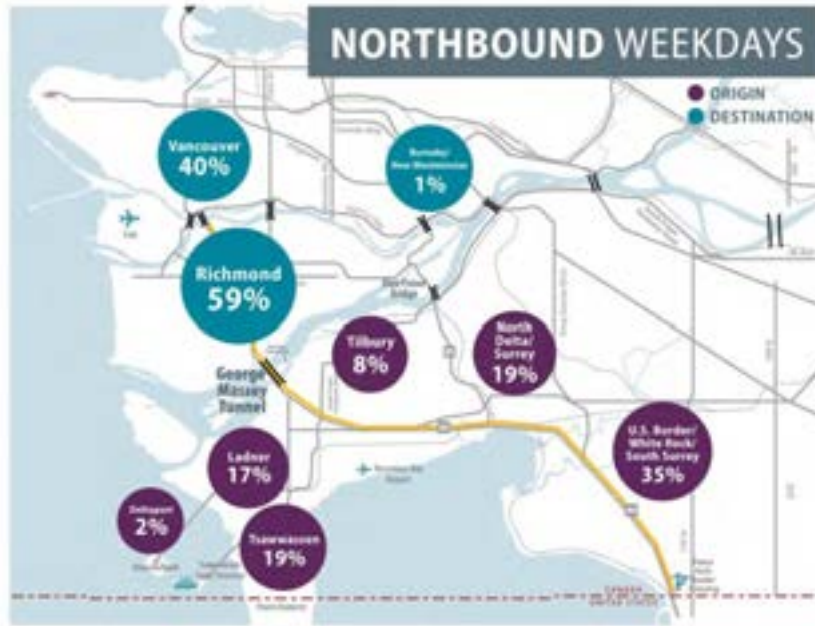

Figure 8: Origins and destinations for northbound traffic on a typical weekday in 2014

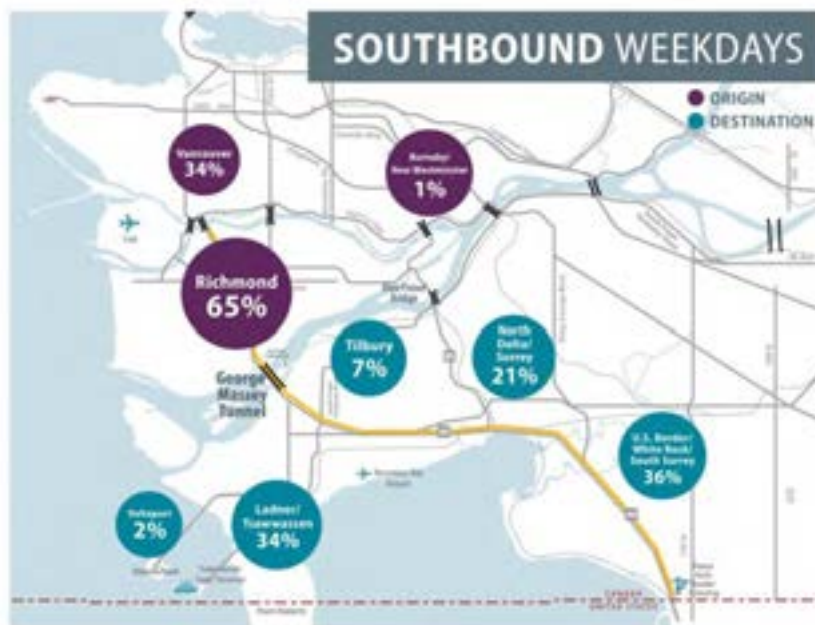

Figure 9: Origins and destinations for southbound traffic on a typical weekday in 2014

Source (Figure 8 and Figure 9): Fall 2014 – Analysis of OD Survey Data Report

Refer to APPENDIX G: ORIGIN – DESTINATION FACTS for details.

3.8. CONGESTION ANALYSIS

Tunnel congestion currently accounts for more than one million hours of vehicle delay annually.

Figure 10 displays an hourly profile based on the 2014 northbound annual average weekday traffic (AAWDT) volumes. The varying congestion zones for the Tunnel reflect the counter-flow operations. The graph shows:

- Despite the three lanes available during the morning peak, there is congestion from just after 6:00 a.m. until 10:30 a.m.
- Conditions are again congested by 3:00 p.m. until after 6:00 p.m. when the counter-flow system reduces the northbound traffic to one lane.
- AFB experiences more severe congestion during the morning peak period.

Figure 10: GMT vs AFB – Northbound – 2014 AAWDT Hourly Profile

Figure 11 displays the hourly profile based on the 2014 southbound annual average weekday traffic (AAWDT) volumes. The graph shows:

- Southbound traffic is reduced to one lane during the morning peak period, which results in heavy congestion from just after 6:00 a.m. to just after 9:00 a.m.
- Congestion resumes by 1:30 p.m. and continues until after 6:30 p.m.
- AFB experiences more severe congestion during the afternoon peak period.

Figure 11: GMT vs AFB – Southbound – 2014 AAWDT Hourly Profile

3.9. TRAVEL TIME DELAY AND RELIABILITY

Northbound Congestion Patterns

As illustrated in Figure 12, congestion delays (additional travel time when compared to free flow travel time) are significant throughout the day, peaking during the morning and afternoon rush periods. The magnitude of the delay varies widely from day to day.

The average northbound morning delay time in October is typically five to ten minutes, but can be as high as 23 minutes during the three-lane morning rush period, and up to 15 minutes during the later-morning two-lane operation. In the afternoon, delays for the one lane of northbound traffic are far greater, averaging about 20 minutes and ranging up to 50 minutes.

Figure 12: Northbound hourly weekday travel time delays along Highway 99

Note: October 13 (Thanksgiving) and October 21 (major incident/delay) are not included.

Note: The analysis is based on average trip times, as recorded by the Ministry's ATIS. The corridor segment analyzed is between Mud Bay (near the Highway 91 interchange) in the south and Westminster Highway in the north.

Southbound Congestion Patterns

As illustrated in Figure 13, southbound traffic delay patterns are also significant in both the morning and afternoon peak periods.

For October weekday mornings, the one lane of southbound Tunnel/Highway 99 traffic experiences an average delay of about seven minutes, ranging up to about 20 minutes.

During the early afternoon two-lane operation, delay times average six minutes and range up to 15 minutes. These delays are partly relieved by the addition of a third lane during the afternoon rush hour, but five-minute delays persist for several hours, with potential delays ranging up to 15 minutes.

Figure 13: Southbound hourly weekday travel time delays along Highway 99

Seasonal Variations in Congestion Patterns

Congestion delays for the Tunnel / Highway 99 traffic are highest for afternoon counter-flow (northbound) traffic, especially during the summer. As illustrated in Figure 14, the average peak delay time for northbound weekday traffic in August is 30 minutes. These delays reflect the high levels of tourist, visitor, and vacation demand for the one available lane of traffic.

Figure 14: Seasonal variation in weekday traffic delays

Travel Time Reliability

As illustrated in Figures 12 to 14, travel time reliability is a significant issue for Tunnel users. Unreliable travel time imposes costs in many different ways:

- Earlier departures to reduce the risk of arriving late, or having the uncertainty of possibly arriving late.
- Rescheduling trips to off-peak periods.
- Traffic diverting to more circuitous routes (for example, northbound afternoon traffic diverting to the AFB / Highway 91 corridor).
- Choosing alternate destinations to avoid using the Tunnel.
- Cancelling or postponing trips that would otherwise be taken.

During the Phase 1 and 2 stakeholder and community consultation process, many Tunnel users indicated that the unpredictability of travel time delays represents as large a cost to them as the delay times themselves.

The new bridge will provide significant benefits in terms of travel time savings and improved reliability. Upon bridge opening, peak period round-trip commuters will save as much as 25 to 35 minutes daily in travel time, along with much greater reliability.

4. TRAFFIC FORECASTING

Understanding future traffic demand is essential to designing an efficient transportation network that will serve all user groups for decades. Traffic forecasting begins with the collection of current traffic data and then applying growth factors for known traffic demand generators such as population and employment growth, travel costs, and regional land use and developments planned to take place during the planning horizon. The traffic model is iteratively calibrated and validated.

Two traffic models have been used for the Project.

Gateway Sub Area Model

The first model used was the Gateway Sub Area Model (GSAM). The GSAM was used for Gateway Program projects between 2003 and 2009. The horizon year of the model is 2031; the model predicts traffic volumes in 2031.

For the purposes of the GMT Project, the GSAM model required refinement, including updates to the road and transit network, truck traffic generators, major future developments, and U.S. border traffic. These updates were made in 2012 and 2013.

Regional Transportation Model

The second model used was the Regional Transportation Model (RTM). The RTM is the most current model developed by TransLink, and has a horizon year of 2045. The RTM uses a sophisticated architecture that allows for much more detailed parameters.

The Project Team tailored the RTM for use with the GMT Project by updating the output values to match the morning and afternoon peak hours at the Tunnel. The truck traffic generators and the highway network also required updating.

Model Comparison

There are many differences between the models. The RTM uses a more advanced modelling architecture that allows for a sophisticated set of assumptions. However, to be effective, traffic models require rigorous iterative calibration and validation. The GSAM model has the advantage of years of additional testing. The different models also provide forecast values for different horizon years, 2031 and 2045.

Both models were used, to assure development of the most complete and comprehensive forecasts.

Critical Assessment

Even the most effective model does not attempt to perfectly predict the future. Rather, it will provide an estimation while identifying the potential for variations, as well as any limitations of the model. Further, the models are designed to forecast at a corridor and regional level, and thus present less reliable volumes at a granular level, such as a turning movement at an interchange. These reasons were kept in mind, when developing forecast volumes. The Project Team developed the GMT forecast volumes as follows:

Step 1: Gather measured and forecast volumes for each traffic movement.

Volumes gathered included 2013 measured volumes, 2014 measured volumes, 2031 GSAM forecast volumes, 2045 RTM forecast volumes, and 2031 & 2045 volumes estimated using 2013/14 measured volumes as a baseline and applying a one percent annual growth rate, based on historical trends.

Step 2: Apply engineering judgment to evaluate and modify Step 1 volumes.

This included: [1] examining the change in traffic volumes between years, both measured (2013 and 2014) and forecast (GSAM 2031 and RTM 2045), [2] checking the forecast volumes against the estimated volumes for the same year, [3] for each of the measured and forecast years, reviewing the volumes for the specific movement and comparing with volumes at surrounding interchanges, highways, intersections, and roadways (reconciling as necessary), and [4] iteratively balancing volumes along the entire Highway 99 corridor.

Modelling results, based on forecast population and employment growth, and considering planned regional road and transit improvements, predict that by 2045 traffic through the existing Tunnel will grow to approximately 100,000 vehicles per day and that traffic over a new 10-lane bridge will be approximately 115,000 vehicles per day. Future traffic volumes are influenced by a number of factors including infrastructure development across the region over the next 30 years.

5. LANING REQUIREMENTS

The laning assessment for the new GMT replacement bridge considered current traffic data, forecast volumes, and experience gained at AFB and PMB. It was determined that a 10-lane bridge (eight lanes for general traffic and two for transit/HOV) would best meet Project requirements for 2045.

Figure 17 in Appendix H illustrates current conditions at GMT and AFB. The current throughput traffic per lane in the morning rush hour is 1600 to 1800 vehicles at GMT, and 1600 to 1900 at AFB. Both crossings are congested during the morning rush hour today.

Figure 18 compares conditions between an eight-lane and a 10-lane bridge in 2022 (opening day). With an eight-lane bridge, conditions remain congested with a demand for 1730 vehicles per general-purpose lane. With a 10-lane bridge, drivers experience free-flow conditions with 1425 vehicles per general-purpose lane.

Figure 19 compares conditions between an eight-lane and a 10-lane bridge in 2045 (design year). With an eight-lane bridge conditions become heavily congested with a demand for 2030 vehicles per general-purpose lane. With a 10-lane bridge, drivers experience significantly reduced congestion, with 1700 vehicles per general-purpose lane.

Further, the additional lane on each side of the 10-lane bridge (as compared to an eight-lane bridge), provides larger vehicles, like container trucks, more time to climb the vertical grade and to safely merge with traffic.

Refer to APPENDIX H: LANING REQUIREMENTS for details.

APPENDIX A: HISTORICAL TRAFFIC DATA

Permanent Count Stations:

- Traffic volumes are collected in 15 minute intervals, 24 hours a day, 365 days a year.
- Many of the permanent count stations were installed in 2004.
- Some collect length bin data for partial vehicle classification.
- SFPR permanent count stations also collect FHWA13 classification data.

TransLink Metro Vancouver Regional Screenline Surveys:

- Data collected at 123 stations along 32 regional screenlines.
- Vehicle volume, classification, and occupancy were collected.
- The project used Screenline Surveys dating back to 1999.

Spring 2012 Traffic Counts:

- Intersection movement counts at 60 Street and 62B Street.
- Interchange movement counts at Highway 17A and Highway 99.
- Traffic volumes through the Tunnel.

Cascade Gateway Data Warehouse USA / CDN Border Crossing Data (2006-2015):

- Volumes
- Delay Times
- Service Rates
- Vehicles in Queue
- Queue Lengths

City of Richmond Traffic Data:

- Traffic volumes automatically counted at all Richmond traffic signals.
- Richmond traffic signals use 1,650 induction loop detectors.
- Traffic is monitored in five minute increments, 24 hours per day, 365 days per year.
- Data is available since 2003.

City of Surrey Traffic Data:

- Hourly volume data dating back to 2010 at 16 permanent traffic volume count stations along arterial roads.
- Daily roadway traffic volumes on a typical weekday through arterial roads based on intersection induction loops.
- Data is collected from 120 traffic cameras.

Ministry of Transportation and Infrastructure:

- Traffic signal data.

Note: The Project Team continues to collect and analyze data from the sources discussed.

APPENDIX B: CURRENT TRAFFIC DATA

DATA SOURCES

Permanent Count Stations: Automated counter recording traffic volumes and vehicle characteristics 24 hours a day, 7 days a week. Typical characteristics collected are length, number of axles, classification and speed.

Short Count Stations: Similar to permanent count stations but implemented for a short time on a temporary basis (48 hours minimum period).

Tube Count Surveys: Air filled tubes laid across the road to capture axle counts and sometimes other vehicle characteristics. Tubes are typically deployed on a temporary basis.

Manual Count Surveys: Vehicle movements and volumes are recorded in the field or with a video camera. Once analysed manual counts can provide accurate data for turning movements at intersections.

Vehicle Classification Surveys: Survey performed to determine the composition of traffic based on vehicle characteristics (e.g. Truck vs. Motorcycle). Up to 13 different vehicle classes can be determined. Can be automated or manual data collection.

Vehicle Occupancy Surveys: Vehicle classification survey performed while recording passenger volumes. This method produces data to determine proportion of trips carried by each mode of travel (e.g. Number of HOV passengers and Bus passengers).

Origin-Destination (OD) Surveys: Survey providing detailed picture of trip patterns and route selection made by vehicles. In this case the survey was conducted using Bluetooth signal analysis. Temporary Bluetooth sensors were deployed along the highway 99 and 91 corridor to gather origin, route and destinations of individual Bluetooth devices.

Travel Time Surveys: Permanent Bluetooth readers are positioned along the highway to gather signatures and determine travel time between locations. Collected by the Ministry ATIS (Advanced Traveller Information System), this travel time information can then be shown on dynamic message boards.

Queue Length Surveys: Field surveys conducted to record how many vehicles are queued at a particular location during set time intervals.

Aerial Photograph Surveys: Photographs taken from an airplane or helicopter that are later analysed to determine queue lengths at key locations.

Safety Assessment Surveys: Collection and review of average collision rates on segments of the study corridor and alternative routes.

ICBC Collision Data: Crash data gathered from reports made to ICBC by insured registered vehicle owners, drivers, pedestrians, and cyclists.

MoTI Collision Information System (CIS) Data: BC MoTI traffic collision data for provincial jurisdiction highways only. The CIS database of collisions is based on motor vehicle accident reports that are generated by police-attended collisions. As such, the database underreports the actual number of collisions because not all collisions are police-attended.

Traffic Signal Data Collection: Vehicle movements and volume data collected by traffic signal controllers at various intersections. Data collected cannot provide classification or turning volumes for lanes with shared movements.

Bike Shuttle Data: Records maintained by Mainroad Lower Mainland Contracting of the number of passengers using the free bicycle shuttle service at the Tunnel.

Transit Passenger Surveys: Field surveys conducted to confirm the bus ridership statistics collected by the vehicle occupancy surveys. Surveyors observed boarding and alighting passengers at established transit facilities.

KEY REPORTS

GMTRP – Traffic Data Collection Report – Fall 2013: A summary of data collected in August and October 2013 for the Project.

GMTRP – Traffic Data Collection Report – Spring 2014: A summary of data collected in April 2014. This report builds on, and complements the data collected in the *Fall 2013 – Traffic Data Collection Report*.

GMTRP – Traffic Data Collection Report – Summer 2014: A summary of data collected in August 2014. This report builds on, and complements the data collected in previous reports.

GMTRP – Traffic Data Collection Report – Fall 2014: A summary of data collected in October 2014. This report builds on, and complements the data collected in previous reports.

GMTRP – Analysis of OD Survey Data – Fall 2013: A summary of the findings of the October and November 2013 origin – destination survey.

GMTRP – Analysis of OD Survey Data – Fall 2014: A summary of the findings of the October and November 2014 origin – destination survey. This report builds on and complements the *Fall 2013 – Analysis of OD Survey Data Report*.

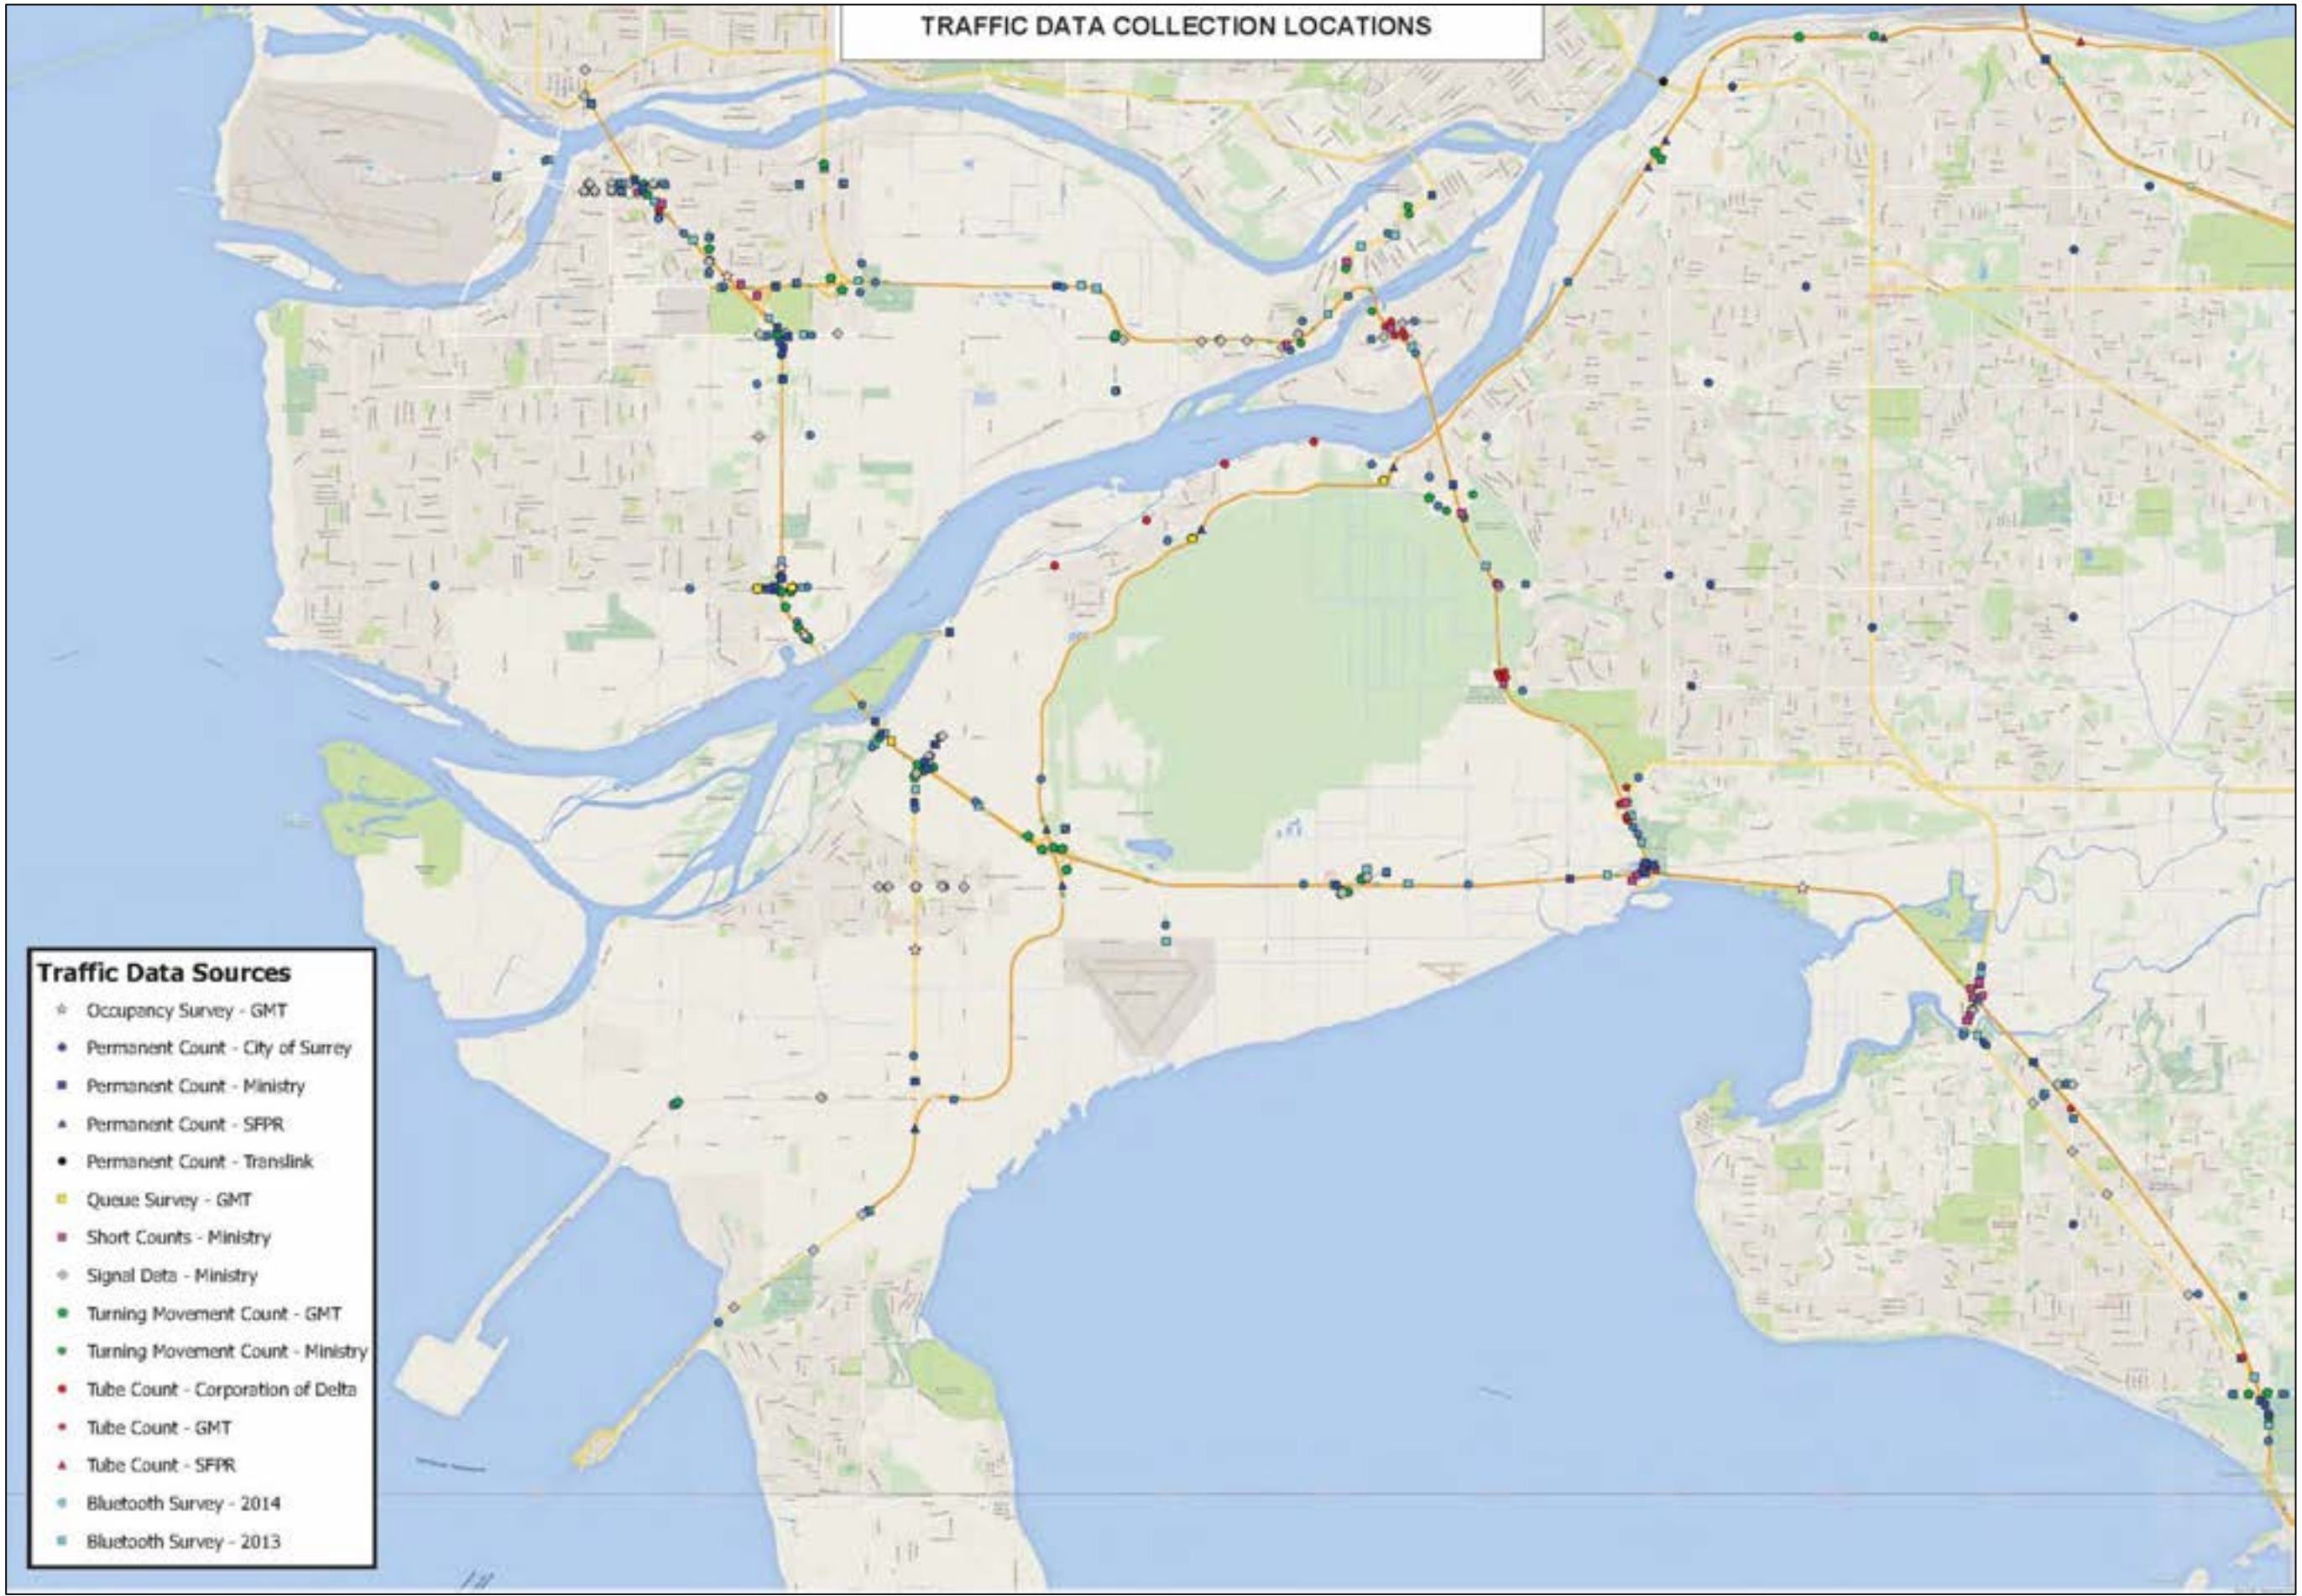

GMTRP – Collision Data Analysis – 2014: Collision data is collected and analyzed to determine average collision rates, trends, and patterns.

| Roadway | 73.5% | 16.6% | 3.4% | 4.9% | 0.1% | 0.5% | 0.7% | 0.2% | 0.1% |

Table 3: Traffic Mode Split by Vehicle Type – Peak Period (2014)

| | SOV | HOV | Light Truck | Heavy Truck | Motor cycles | Taxi & Limo | Transit Bus | Other Bus | Other Vehicle |
|---------------------------------|-------|-------|-------------|-------------|--------------|-------------|-------------|-----------|---------------|
| NB AM Peak Period (6:00-9:00) | 83.5% | 10.4% | 2.6% | 2.2% | 0.1% | 0.4% | 0.6% | 0.1% | 0.0% |
| NB PM Peak Period (15:00-18:00) | 63.3% | 28.0% | 2.0% | 4.0% | 0.1% | 0.9% | 1.1% | 0.4% | 0.2% |
| SB AM Peak Period (6:00-9:00) | 70.8% | 14.2% | 3.4% | 8.2% | 0.3% | 0.5% | 2.0% | 0.7% | 0.1% |
| SB PM Peak Period (15:00-18:00) | 77.4% | 16.7% | 2.1% | 2.6% | 0.1% | 0.3% | 0.5% | 0.1% | 0.1% |

Note: Data from the October 23, 2014 Vehicle Occupancy performed by TransTech as part of the GMT Data Collection Program Fall 2014.

Table 4: Traffic Mode Split by Vehicle Type – Peak Hour (2014)

| | SOV | HOV | Light Truck | Heavy Truck | Motor cycles | Taxi & Limo | Transit Bus | Other Bus | Other Vehicle |
|-------------------------------|-------|-------|-------------|-------------|--------------|-------------|-------------|-----------|---------------|
| NB AM Peak Hour (6:30-7:30) | 84.0% | 9.7% | 2.5% | 2.5% | 0.2% | 0.4% | 0.6% | 0.1% | 0.0% |
| NB PM Peak Hour (16:30-17:30) | 64.4% | 28.8% | 1.7% | 2.2% | 0.2% | 0.8% | 1.3% | 0.6% | 0.1% |
| SB AM Peak Hour (6:30-7:30) | 74.9% | 10.6% | 2.8% | 8.8% | 0.3% | 0.2% | 2.0% | 0.3% | 0.0% |
| SB PM Peak Hour (16:30-17:30) | 78.4% | 16.5% | 1.7% | 2.3% | 0.1% | 0.3% | 0.5% | 0.1% | 0.1% |

Note: Data from the October 23, 2014 Vehicle Occupancy performed by TransTech as part of the GMT Data Collection Program Fall 2014.

Table 5: Northbound Peak Hour (6:30-7:30) Traffic Composition

| | October 2013 | | October 2014 | |
|--------------------------|--------------|--------------|--------------|--------------|
| | Volume | % of Traffic | Volume | % of Traffic |
| Passenger Vehicle | 4,732 | 93.4% | 4,752 | 93.6% |
| Cars | 4,712 | 93.0% | 4,749 | 93.5% |
| Motorcycles | 20 | 0.4% | 3 | 0.1% |
| Buses | 40 | 0.8% | 31 | 0.6% |
| Trucks | 295 | 5.8% | 294 | 5.8% |
| Light Trucks | 162 | 3.2% | 157 | 3.1% |
| Heavy Trucks | 133 | 2.6% | 114 | 2.2% |
| Container Trucks | N/A | N/A | 23 | 0.5% |
| Total | 5,067 | 100% | 5,077 | 100% |

Note: Data taken from 2013 and 2014 Manual Counts performed at the George Massey Tunnel. Values are the results of a Tuesday count performed in October of each given year.

Table 6: Southbound Peak Hour (16:30-17:30) Traffic Composition

| | October 2013 | | October 2014 | |
|--------------------------|--------------|--------------|--------------|--------------|
| | Volume | % of Traffic | Volume | % of Traffic |
| Passenger Vehicle | 4,601 | 96.2% | 4,627 | 96.5% |
| Cars | 4,581 | 95.8% | 4,622 | 96.4% |
| Motorcycles | 20 | 0.4% | 5 | 0.1% |
| Buses | 31 | 0.7% | 27 | 0.5% |
| Trucks | 149 | 3.1% | 143 | 3.0% |
| Light Trucks | 78 | 1.6% | 77 | 1.6% |
| Heavy Trucks | 71 | 1.5% | 39 | 0.8% |
| Container Trucks | N/A | N/A | 27 | 0.6% |
| Total | 4,781 | 100% | 4,797 | 100% |

Note: Data taken from 2013 and 2014 Manual Counts performed at the George Massey Tunnel. Values are the results of a Tuesday count performed in October of each given year.

APPENDIX D: TRUCK TRAFFIC FACTS

REGIONAL CONTEXT

Table 7: Total Truck Volumes at Major River Crossings – Daily (7:00 to 17:30)

| Crossing | 2008 Truck Volume | 2014 Truck Volume | Growth |
|------------------------------|-------------------|-------------------|-------------|
| George Massey Tunnel | 5,270 | 5,740 | 9.0% |
| Alex Fraser Bridge | 6,500 | 6,850 | 5.4% |
| Pattullo Bridge | 3,340 | 3,840 | 15.1% |
| Port Mann/Golden Ears Bridge | 6,980 | 7,760 | 11.2% |
| Pitt River Bridge | 3,090 | 3,420 | 10.6% |
| All Crossings | 25,170 | 27,600 | 9.7% |

Note: Data taken from the 2008 and 2014 Metro Vancouver Truck Classification and Dangerous Goods Surveys.

CORRIDOR CONDITIONS – HIGHWAY 99 & HIGHWAY 91

Table 8: Truck (Light & Heavy) Volumes at GMT & AFB – AM Peak, Midday, PM Peak

| | George Massey Tunnel | | | | Alex Fraser Bridge | | | |
|-------------------------------------|----------------------|--------------|--------------|--------------|--------------------|--------------|--------------|--------------|
| | 2008 | | 2011 | | 2008 | | 2011 | |
| | Vol. | % | Vol. | % | Vol. | % | Vol. | % |
| Morning Peak (06:00-09:00) | 999 | 5.4% | 1,207 | 6.9% | 1,561 | 6.9% | 1,508 | 7.0% |
| Light Truck | 307 | 1.7% | 260 | 1.5% | 617 | 2.7% | 519 | 2.4% |
| Heavy Truck | 692 | 3.7% | 947 | 5.4% | 944 | 4.2% | 989 | 4.6% |
| Midday (09:00-15:00) | 3,501 | 12.3% | 4,151 | 14.5% | 3,922 | 11.5% | 3,978 | 11.3% |
| Light Truck | 1,046 | 3.7% | 911 | 3.2% | 1,791 | 5.2% | 1,564 | 4.4% |
| Heavy Truck | 2,455 | 8.7% | 3,240 | 11.3% | 2,131 | 6.3% | 2,414 | 6.8% |
| Afternoon Peak (15:00-19:00) | 930 | 4.0% | 950 | 4.1% | 1,583 | 4.9% | 2,013 | 5.8% |
| Light Truck | 286 | 1.2% | 316 | 1.4% | 695 | 2.1% | 798 | 2.3% |
| Heavy Truck | 644 | 2.8% | 634 | 2.7% | 888 | 2.8% | 1,215 | 3.5% |

Note: Data from 2008 and 2011 TransLink Screenline Surveys.

Note: The % column shows truck traffic volume as a percentage of total traffic volume.

Note: Data taken from *October 2013 and October 2014 Manual Count Surveys*. Container trucks were not distinguished in the October 2013 counts. AM period 6:00 – 9:00, MD period 10:00 – 13:00, PM period 14:00 – 18:00.

APPENDIX E: TRANSIT FACTS

REGIONAL CONTEXT

Table 10: South Arm Bridges – Average Weekday Bus Volumes and Ridership

| Crossing | Number of Bus routes | Bus Volume | Passenger Volume |
|----------------------|----------------------|----------------------|------------------|
| George Massey Tunnel | 9 | 559 | 10,535 |
| Alex Fraser Bridge | 3 | 250 | 3,853 |
| Pattullo Bridge | 1 | 11* | 350* |
| Port Mann Bridge | 1 | 137* | 2,500* |
| Golden Ears Bridge | 1 | 75 | 735 |
| SkyBridge | N/A | 230 trains per day** | 51,000** |

Note: Data taken from the 2011 TransLink Screenline Survey, except as noted:
 * Data taken from TransLink 2014 Bus Service Performance Review (no PMB or PB buses in 2011).
 ** Based on 2015 Transit Schedule.

Table 11: Peak Hour Transit Ridership

| Crossing | Peak Hour Volume |
|----------------------|------------------|
| SkyBridge | 6,500 |
| Canada Line | 5,000 |
| George Massey Tunnel | 1,350 |
| Alex Fraser Bridge | 425 |
| Port Mann Bridge | 240* |

Note: Data taken from 2011 Metro Vancouver Screenline Report.
 * Based on 6 buses/hour and average peak passenger load of 40 (2014 TransLink Bus Service Performance Review).

APPENDIX H: LANING REQUIREMENTS

10 Lanes

A 10-lane bridge would have one dedicated transit/HOV lane in each direction located adjacent to the median of the highway. The four remaining lanes in each direction would be for general purpose (GP) traffic for a total of five lanes in each direction.

This option would provide a lane on the right hand side of the highway for trucks and other slower moving traffic as they navigate the grade of the new bridge (similar to the Alex Fraser Bridge). This lane would also be utilized by traffic merging to/from the Highway 17A and Steveston Highway Interchanges. By providing an additional lane over the eight-lane option; the effect of weaving across all highway lanes will be reduced.

The 10-lane bridge option provides increased capacity over existing conditions, with the addition of a dedicated transit/HOV lane and a general purpose lane.

8 Lanes

An eight-lane bridge would also have a dedicated transit/HOV lane in each direction located adjacent to the median of the highway. The three remaining lanes would be for GP traffic for a total of four lanes in each direction.

This option would not provide an additional lane for trucks and other slower moving traffic as they navigate the grade of the new bridge (similar to the Alex Fraser Bridge). With only three GP traffic lanes, vehicles merging to/from the Highway 17A and Steveston Highway Interchanges will weave into and mix with through traffic. The absence of an additional lane for slow moving and weaving traffic would lead to heavier congestion; compromising travel times for the faster moving through traffic.

The eight-lane bridge option does not provide for increased capacity other than the addition of a transit/HOV lane. An eight-lane bridge would result in peak-period congestion on opening day.

Discussion

The following diagram demonstrates existing conditions at the George Massey Tunnel and the Alex Fraser Bridge.

Figure 17: Laning Diagram – NB 2014 AM Rush Hour – GMT vs AFB

The following diagram demonstrates 2022 forecast conditions at the George Massey Tunnel under the 10 and 8 lane bridge scenarios.

Figure 18: Laning Diagram – NB 2022 AM Rush Hour – Eight vs Ten Lanes

On opening day during the AM rush hour a 10-lane bridge would operate under free flow conditions. On opening day during the AM rush hour an eight-lane bridge would be in a congested state similar to today.

There is a significant difference in rush hour volume when comparing existing traffic in 2014 to anticipated traffic at the new bridge in 2022 (5100 to 6700 vehicles per hour) due to additional capacity. Increased capacity allows traffic to leave at their desired travel time rather than staggering their trip to avoid congestion related delays. This is empirically evident based on the Port Mann Bridge experience. The Port Mann Bridge opened on December 1, 2012 and the increase in rush hour volume is evident in the 2013 data. This is illustrated in Figure 20 and 21 in Appendix I below.

The following diagram demonstrates 2045 forecast conditions at the George Massey Tunnel under the 10- and eight-lane bridge scenarios.

GMT 2045 Traffic:
7900 Vehicles/Hour
(1100 HOV included)

GMT 2045 Traffic:
7500 Vehicles/Hour
(1400 HOV included)

Figure 19: Laning Diagram – NB 2045 AM Rush Hour – Eight vs Ten Lanes

In the 10-lane option, vehicles per lane are returning to levels similar to current conditions at the existing tunnel. The level of congestion will be mitigated to a degree by the improved ramps and interchanges connecting to the bridge.

In the eight-lane option the bridge is experiencing heavy congestion during rush hour beyond what is currently occurring at the tunnel.

APPENDIX I: PORT MANN BRIDGE WEEKDAY TRAFFIC PROFILE

As illustrated in the following graphs, the Port Mann Bridge is experiencing a three-year trend of increased use in the peak direction during peak periods and an overall decreased use during the remainder of the day. Toll diversion appears to have peaked in 2014.

Figure 20: PMB EB weekday traffic profile.

Figure 21: PMB WB weekday traffic profile.

1 Introduction

Background

Steer Davies Gleave was appointed by the Massey Tunnel Replacement Project (the Client) to develop an independent analysis of traffic forecasts for the Project to validate the traffic forecasts developed internally by the Client.

The work carried out includes:

- Analysis of historical traffic patterns
- Review of socio-economic development in the region
- Development of a spreadsheet-based forecast model, including:
 - Econometric facility model (peak/off-peak split into car and trucks)
 - Estimation of tolling and capacity increase impacts
 - Development of traffic forecasts to December 2045

The Project

The Massey Tunnel opened in 1959 and is a key component of Metro Vancouver's transportation system. In 1981 counter-flow measures were introduced, using a reversible lane system to increase traffic flow during peak periods in the peak direction, and this continues to this day. The tunnel carried around 80,000 daily vehicles in 2014. Figure 1.1 shows the location of the tunnel.

Figure 1.1: Massey Tunnel location

Source: Massey Tunnel Replacement Project

In response to growing concerns about the impact of congestion, and recognizing that the existing tunnel has about 10 years of useful life remaining, the Province of British Columbia has committed to constructing a bridge replacement. Construction of the new bridge on the existing Highway 99 corridor is scheduled to begin in 2017 and the new crossing could be operational by 2021.

2 Traffic Analysis

Massey Tunnel and Alex Fraser Bridge data has been analyzed, as both facilities offer a similar option to travel between Richmond and Delta, Surrey and the US border. Future construction and/or tolls on the Massey Tunnel will clearly influence the traffic on the Alex Fraser Bridge.

Data Availability

Traffic data for the Massey Tunnel and Alex Fraser Bridge was collected from BC Ministry of Transportation and Infrastructure (MoTI) data¹ or provided by the Massey Tunnel Replacement Project office. Table 2.1 summarizes the data available for this study.

Table 2.1: Traffic data availability

| Crossing | Traffic volumes | Vehicle classification | Time of day | Source |
|----------------------|--|--|--|--------------|
| George Massey Tunnel | Jan 2004 - Jun 2015 | Partially available | Jan 2004 - Jun 2015 | MoTI, client |
| Alex Fraser Bridge | Jan 2004 - Jun 2015 | Jan 2004 - Jun 2015 | Jan 2004 - Jun 2015 | MoTI, client |
| Port Mann Bridge | Jan 2004 - Mar 2012 Nov 2012 - Jul 2015 | Jan 2004 - Mar 2012 Nov 2012 - Jul 2015 | Jan 2004 - Mar 2012 Nov 2012 - Jul 2015 | Client |

The data listed in the table represents an extensive dataset. Note the following regarding the data reviewed:

- There is no complete historical vehicle classification data available for the Massey Tunnel.
- There are some data gaps for Massey Tunnel and Alex Fraser (identified later in this section).

Traffic Data

Historical traffic data for the Massey Tunnel and Alex Fraser Bridge is presented in Figure 2.1.

¹ <http://www.th.gov.bc.ca/trafficdata/index.html>

Figure 2.1: Massey Tunnel (MT) and Alex Fraser (AF) Daily Traffic

Source: MoTI Traffic Data Program

Figure 2.1 shows the monthly daily traffic for the Massey Tunnel is consistently lower than Alex Fraser by around 18% (average between 2004 and 2015).

Note that no traffic data was available for the Massey Tunnel for the following periods:

- October 2004 – March 2005
- May 2007
- July 2011 – August 2011
- August 2012 – November 2012
- January 2013

For Alex Fraser Bridge the following data was missing:

- February 2011 to April 2011
- May 2013.

Data in Figure 2.1 has missing values replaced with traffic based on traffic growth, historical information and monthly profile data. The figure shows a decrease in traffic for Massey Tunnel in the period analyzed. This is confirmed with the traffic presented in Table 2.2 where annual traffic growth shows a reduction of -0.7% between 2005 and 2014. Alex Fraser Bridge traffic shows permanent AADT for 2014 of about 108,000, 10% more than the AADT for 2005 (98,000).

Table 2.2: Massey Tunnel and Alex Fraser Bridge annual traffic

| | George Massey Tunnel | | | Alex Fraser Bridge | | |
|---------------------------|----------------------|--------|--------|--------------------|---------|---------|
| | AADT | AAWDT | AAWET | AADT | AAWDT | AAWET |
| 2005 | 85,000 | 90,000 | 72,000 | 98,000 | 108,000 | 72,000 |
| 2006 | 83,000 | 87,000 | 69,000 | 102,000 | 111,000 | 75,000 |
| 2007 | 82,000 | 87,000 | 68,000 | 98,000 | 107,000 | 73,000 |
| 2008 | 80,000 | 84,000 | 67,000 | 99,000 | 108,000 | 73,000 |
| 2009 | 81,000 | 85,000 | 68,000 | 102,000 | 111,000 | 77,000 |
| 2010 | 82,000 | 87,000 | 69,000 | 103,000 | 112,000 | 77,000 |
| 2011 | 82,000 | 86,000 | 68,000 | 103,000 | 112,000 | 77,000 |
| 2012 | - | 86,000 | - | 105,000 | 114,000 | 80,000 |
| 2013 | 79,000 | 82,000 | 68,000 | 107,000 | 116,000 | 84,000 |
| 2014 | 79,000 | 84,000 | 66,000 | 108,000 | 116,000 | 85,000 |
| Difference (2005 to 2014) | -6,000 | -6,000 | -6,000 | +10,000 | +8,000 | +13,000 |
| Annual growth | -0.7% | -0.7% | -0.9% | +1.0% | +0.7% | +1.7% |

Source: MoTI Traffic Data Program²

As indicated previously there is limited historical vehicle classification data for the Massey Tunnel. Therefore, we estimated the vehicle classification data for the tunnel based on a combination of localised traffic counts and a permanent counter (site P67-13) located on Highway 99 north of the Massey Tunnel. Traffic is shown in Figure 2.2.

Figure 2.2: Massey Tunnel and Alex Fraser Bridge classified monthly traffic

Source: MoTI Traffic Data Program. Massey Tunnel truck percentages estimated.

Between 2004 and 2015, the vehicle split for the Massey Tunnel is about 92% for cars and 8% for trucks, whereas for Alex Fraser Bridge it is 91% for cars and 9% for trucks. Overall traffic growth on the Massey Tunnel and the Alex Fraser Bridge is determined by car traffic.

² AADT = Annual Average Daily Traffic, AAWDT = Annual Average Weekday Traffic, AAWET = Annual Average Weekend Total

Traffic Demand Analysis

Figure 2.3 shows a slight reduction in Massey Tunnel traffic during the peak hours³ (from 6,300 vehicles/hr in 2005 to 5,800 vehicles/hr in 2014). The average traffic for trucks during peak and off peak hours is about the same (around 375 vehicles).

Figure 2.3: Massey Tunnel classified average hourly Peak and Off Peak traffic

Source: MoTI Traffic Data Program

There is a higher truck traffic on Alex Fraser Bridge compared to Massey Tunnel as shown in Figure 2.4 with the peak period showing higher flows than the off peak.

Figure 2.4: Alex Fraser classified average hourly Peak and Off Peak traffic

Source: MoTI Traffic Data Program

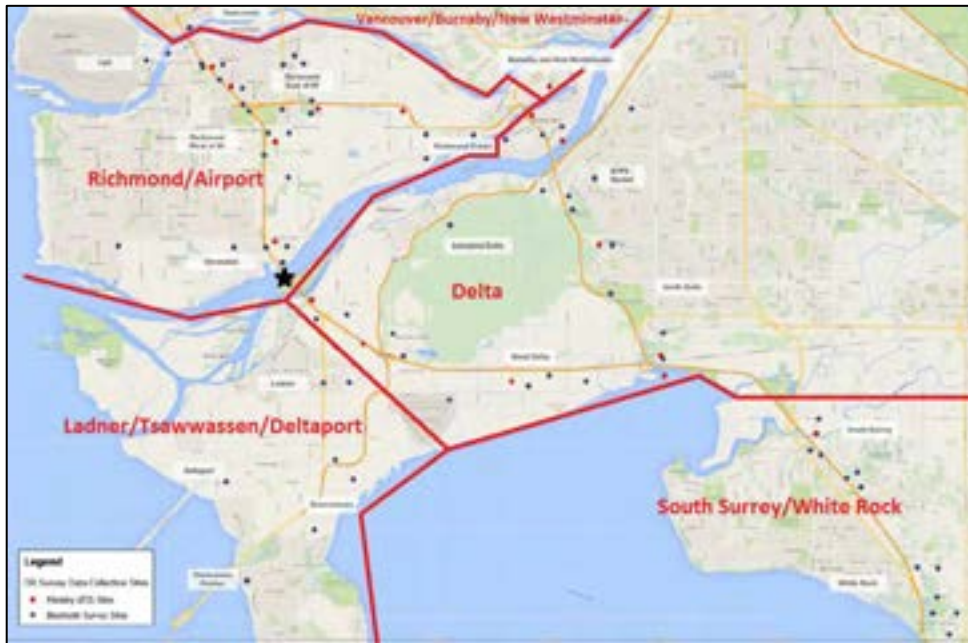

The hourly average peak traffic for the Alex Fraser Bridge is 7,800 vehicles/hr, where 85% is made up by car traffic.

³ Peak hours = 6:00am to 9:00am and 3:00pm to 6:00pm on weekdays

Origin-Destination Data

Latest OD survey data is available for fall 2014. The survey was conducted with Bluetooth readers at 70 locations over a two-week period in late October/early November. Bluetooth readers were grouped into five geographic areas as shown in Figure 2.5.

Figure 2.5: OD survey analysis areas

Source: Analysis of OD Survey Data, Fall 2014 (Parsons)

Two of the readers are located to the north of the Fraser River and three to the south (Massey Tunnel is identified as the star in the figure) and 507,000 trips were detected during the two week period. Figure 2.6: and Figure 2.7 present the distribution of southbound and northbound trips for trips recorded South of the Fraser.

Figure 2.6: Time of day distribution of SB weekday trip destinations (South of the Fraser)

Source: Analysis of OD Survey Data, Fall 2014 (Parsons)

Figure 2.7: Time of day distribution of NB weekday trip origins (South of the Fraser)

Source: Analysis of OD Survey Data, Fall 2014 (Parsons)

In the AM period traffic destined to South Surrey/White Rock represent 22% of trips while in the PM peak this increases to 37% suggesting a heavy commuter flow. In the northbound direction the proportions from South Surrey/White Rock are reversed i.e. 35% of the trips originate from there in the AM period while only 24% in the PM peak. Lardner/Tsawwassen/Deltaport area generally represents the highest proportions of trips.

Figure 2.8 and Figure 2.9 present the distribution of southbound and northbound trips for trips recorded North of the Fraser.

Figure 2.8: Time of day distribution of SB weekday trip origins (North of the Fraser)

Source: Analysis of OD Survey Data, Fall 2014 (Parsons)

Figure 2.9: Time of day distribution of NB weekday trip destinations (North of the Fraser)

Source: Analysis of OD Survey Data, Fall 2014 (Parsons)

Trips north of the Fraser show a consistent geographical pattern throughout the day. Around 65% of southbound trip origins are from Richmond/YVR while 60% of the northbound trips destinate there. The one ‘outlier’ are northbound trips in the evening period (64%) where the airport appears to increase the proportion slightly.

Travel Times

Travel time data is collected by the Ministry’s Advanced Traveller Information System (ATIS) and Highway 99 travel times are summarised in Figure 2.10. It shows the impact of peak traffic on travel times, particularly in the northbound direction where travel times can double compared to free flow conditions. This is likely caused by traffic flow volumes and fact that only 1 lane operates in the northbound direction in the PM peak.

Figure 2.10: Highway 99 travel times

Source: Traffic Data Collection Report, Fall 2014 (Parsons)

3 Model Development

Data Inputs

Econometric models estimate the relationship between socio-economic factors (such as GDP, employment, income, etc.) as well as prices (such as fuel or tolls) on traffic. Given detailed data, one can develop robust estimates of the various elasticities influencing demand. The estimated models can also be used, in turn, to simulate the impacts of future economic growth on traffic demand.

Traffic Data

Section 2 presented Massey Tunnel and Alex Fraser historical traffic data split into cars and trucks.

Socio Economic Parameters

Historical national, provincial and metropolitan economic data from Statistics Canada was reviewed to develop the econometric models. This included a wide range of data sources ranging from GDP to border crossings. All the variables are potential variables for the econometric models according to economic theory, and in order to select the best predictors of traffic a series of statistical analyses were run.

Model Development

An extensive number of model estimations were made as part of this work. This involved the following parameters:

- Gas and diesel prices
- Canada, BC and Metro Vancouver employment (total and 6 different employment sectors)
- Canada, BC and Metro Vancouver population
- Canada and BC GDP
- Canada, BC and Metro Vancouver retail trade
- Canada, BC and Metro Vancouver building permits
- BC manufacturing sales
- Canada and BC weekly earnings
- Canada and BC travel accommodation
- Exchange rates
- Border crossings

The specifications for each model developed are detailed below. These are the models showing the variables found to have the highest explanatory power in the model. The variables are converted to natural logarithms (denoted as ln) which means that estimated coefficients are equal to elasticities. These measures detail the effect of a % increase in the variable in terms of a resulting % change in traffic.

Peak Model - Passenger vehicles

The summary results for the peak model developed for passenger vehicles are shown in **Table 3.1**. Note that this model was based on Alex Fraser peak car traffic only as Massey Tunnel shows effectively no peak growth since 2004. Specific coefficients for seasonal variations and special events (Stanley cup finals in 2011, weather conditions in Dec 2008) are not shown but were also included in the analysis.

Table 3.1: Peak model: Passenger vehicles

| | Coefficient | P value |
|---------------------------------------|-------------|---------|
| ln(British Columbia Total Employment) | 0.308*** | 0.00 |
| Constant | 8.261*** | 0.00 |

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$ where p is the probability that the observation was not statically significant. The lower the p , the higher the statistical significance.

Peak Model - Commercial vehicles

The summary results for the peak model developed for commercial vehicles are shown in **Table 3.2**. The model considers peak truck traffic for the Massey Tunnel and Alex Fraser bridge. While detailed coefficients are not shown, the models included controls for monthly seasonal variations, heavy snow in December 2008 and large increase in month to month truck traffic observed in 2014 and 2015 for construction impacts in the area.

Table 3.2: Peak model: Commercial vehicles

| | Coefficient | P value |
|---------------------|-------------|---------|
| ln(Real GDP Canada) | 0.602*** | 0.000 |
| Constant | 0.0787 | 0.48 |

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$ where p is the probability that the observation was not statically significant. The lower the p , the higher the statistical significance.

Off Peak Model - Passenger vehicles

The summary results for the off peak model developed for passenger vehicles are shown in **Table 3.3**. The model considers growth in total off-peak vehicles for Massey Tunnel and Alex Fraser Bridge. Gas prices are not statistically significant but do have the correct sign (increase in gas prices will result in reduction in traffic) while British Columbia total employment and the constant are strongly significant.

Table 3.3: Off Peak model: Passenger vehicle

| | Coefficient | P value |
|---|-------------|---------|
| ln(Real British Columbia gas prices) ⁴ | -0.0213 | 0.732 |
| ln(British Columbia Employment) | 0.796*** | 0.000 |
| Constant | 5.522*** | 0.000 |

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$ where p is the probability that the observation was not statically significant. The lower the p , the higher the statistical significance.

⁴ Model uses the 3 month moving average for fuel prices

Off Peak Model - Commercial vehicles

The summary results for the off peak model developed for commercial vehicles are shown in **Table 3.4**. The model considers off-peak truck traffic for the Massey Tunnel and Alex Fraser Bridge. Whilst detailed coefficients are not shown the models included controls for seasonal variations, controls for the heavy snow in 2008 and large increase in month to month truck traffic observed in 2014 and 2015 for construction impacts in the area.

Table 3.4: Off Peak model: Commercial vehicle

| | Coefficient | P value |
|---------------------|-------------|---------|
| ln(Real GDP Canada) | 1.009*** | 0.00 |
| Constant | 5.291*** | 0.01 |

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$ where p is the probability that the observation was not statically significant. The lower the p , the higher the statistical significance.

Forecast Comparison

Each of these variables is theoretically sound, and together form a comprehensive model to forecast traffic. Gas prices increase the price of travel and reduce the number of trips, employment is a driver of both trips and demand and GDP (economic activity) is closely linked to travel demand.

Figures below compare the modelled flows against observed traffic flows for the various models developed.

Figure 3.1: Peak Model: Passenger vehicles

Source: Steer Davies Gleave

Figure 3.2: Peak Model: Commercial vehicles

Source: Steer Davies Gleave

Figure 3.3: Off Peak Model: Passenger vehicles

Source: Steer Davies Gleave

Figure 3.4: Off Peak Model: Commercial vehicles

Source: Steer Davies Gleave

The models reflect past traffic patterns accurately and generally show a robust forecasting tool has been developed. Note the following:

- Peak model based on Alex Fraser traffic data, as Massey Tunnel shows negative peak traffic growth since 2004 (see Figure 2.1) and this makes the development of an econometric growth model challenging.
- There was very high truck traffic growth between 2006 and 2008. This made calibration of econometric models in that period challenging as observed data completely outside the trend growth observed between 2004 to 2006 and 2008 to 2014.

4 Traffic Forecasts

Forecasting Inputs

Socio Economic Forecasts

Chapter 3 identified the socioeconomic variables which derive traffic growth and these are detailed below.

Gas Prices

For gasoline prices we used United States Energy Information Agency (EIA) forecasts for the Northwest region. While gas prices are lower in the US, we consider that the forecast captures the overall growth and fluctuations expected. Note that they have been adjusted to the average British Columbia market price to reflect the different gas tax rates. Figure 4.1 shows historical and forecast British Columbia gas prices, adjusted for inflation. It shows the high gas prices in the summers of 2008 and 2012 and the decline in 2015. EIA suggests price recovery in the near future to 2016 and gradually increasing afterwards.

Figure 4.1: British Columbia Gas Prices

BC Employment

Figure 4.2 details the historical and forecast growth for BC employment. In the near term there is reasonable growth in employment expected at 1.5-2.0% per year but this slows down to less than 1.5% after 2018. Employment growth is expected to slow down below 1% beyond 2020.

Figure 4.2: BC Employment

Source: Statistics Canada (historical), Conference Board of Canada (forecast)

Canada GDP

Figure 4.3 presents the historical and forecast growth for Canadian GDP. It shows growth of around 2.3% in the near term and this slows down to around 2% in the longer term.

Figure 4.3: Canada GDP

Source: Statistics Canada (historical), Conference Board of Canada (forecast)

New Bridge Impact

Econometric models provide a robust method to estimate underlying traffic growth driven by the parameters presented in Section 3. However we need to estimate the impact of the crossing capacity expansion (from 4 lanes to 10 lanes when completed) and the introduction of tolls.

For the development of traffic forecasts for the Massey Tunnel, we have reviewed Port Mann Bridge traffic data as a proxy for capacity improvements and inclusion of a toll. Figure 4.4 shows bridge traffic since 2004 (note that traffic data between April and October 2012 was missing and estimated for the purposes of this analysis).

Figure 4.4: Monthly Average Daily Traffic (MADT) – Port Mann Bridge

Source: Massey Tunnel Replacement Project

The figure shows traffic decreasing since 2009, with economic recession and construction impacts likely to be the main factors. A reduction in traffic can be observed once the tolls were introduced in December 2012 (\$1.50 toll per car). A further reduction can be observed when the toll was increased to \$3.00 in December 2013 as the introductory toll rate ended.

Figure 4.5 presents the 12 month traffic moving average. The figure shows a negative growth trend in car traffic (which is over 90% of the total traffic) since mid-2009, from around 120,000 vehicles/day to 94,000 vehicles/day in January 2015.

Figure 4.5: 12 month average daily traffic – Port Mann Bridge

Source: Massey Tunnel Replacement Project

Compared to car traffic, truck traffic at Port Mann Bridge has not been affected to such a degree. In fact, the truck MADT since the opening of the new bridge has increased from 9,300 trucks/day to around 10,000 trucks/day.

The Port Mann traffic impacts are summarized in Table 4.1. It suggests that the impact of the introduction of a \$3.00 toll (similar level envisaged for the new Massey Tunnel replacement) is a 13% reduction in car traffic and a 4.8% increase in truck traffic.

Table 4.1: Port Mann Bridge traffic impact

| Port Mann Bridge | Car | Total Truck | Total Traffic |
|---|--------|-------------|---------------|
| First year traffic impact (2012 vs 2013) | | | |
| Car toll = \$1.5 | -8.2% | +7.4% | -6.8% |
| Light Truck toll = \$4.5 | | | |
| Heavy Truck toll = \$9.0 | | | |
| Second year traffic impact (2012 vs 2014) | | | |
| Car toll = \$3.0 | -13.0% | +4.8% | -11.4% |
| Light Truck toll = \$6.0 | | | |
| Heavy truck toll = \$9.0 | | | |

Source: Steer Davies Gleave calculations of Massey Tunnel Replacement Project data

The project toll values were provided by the project office. Note that we are assuming that tolls will be increasing in line with inflation i.e. no increase in tolls in real terms.

Induced Demand

Induced traffic refers to trips that are generated as a result of new road infrastructure, such as the new bridge and associated works. Trips will be generated as new travel or existing corridor users travel more frequently due to the convenience and time savings created by the new bridge. Furthermore current trips that do not involve a crossing of the Fraser may divert across the river due to the easier access associated with the bridge.

The Massey Tunnel replacement is providing additional capacity (and reliability) across the Fraser River with significant travel time savings in a number of origin-destination movements both sides of the river.

While induced demand has long been recognized as a result of the introduction of new transportation infrastructure, there is uncertainty in estimating induced traffic due to the length of the impact and the extent of it. We have based our induced traffic estimate on an elasticity function whereby the number of new trips is derived from the forecast travel cost with and without the new facility and applying an elasticity of 0.5 i.e. a 10% reduction in travel costs results in a 5% increase in traffic demand.

Based on the travel cost saving estimate we have calculated an induced demand estimate of 3%. Note the following:

- Applied to peak cars only - off peak travel times are equivalent to free flow travel times already (see Figure 2.10) and truck traffic is non-discretionary
- Induced traffic might take some time to materialize after the new infrastructure is in place. We have phased its full impact and assumed the following rates of induced traffic in the first years following the completion of the project (1% in 2021, 2% in 2022 and 3% by 2023)

Post 2035 Growth

Forecast socioeconomic information extends to 2035. This is in line with forecasts generally as a result of issues with very long term forecasting and the high level of risk and uncertainty for such timescales. For the purposes of this study we have assumed that growth is reduced by half to 2045.

Traffic Forecasts

The resulting traffic forecasts are shown in Figure 4.6.

Figure 4.6: Massey Tunnel Replacement traffic forecasts

Source: Steer Davies Gleave

The forecasts show the following:

- Slight increase in car traffic from 2014 to 2020 as off peak growth assumed (0.9% annual growth). Trucks grow considerably higher at 1.8% in line with historical growth patterns
- Toll impact represented in 2021 with car traffic reduction and based on local experience from the Port Mann Bridge
- Growth from 2022 to 2035 based on econometric growth and induced demand generated (0.7% annual growth for cars). Truck growth continues at a faster rate (1.8%)

Forecasts split into car, Light Truck and Heavy Truck and included in Appendix B.

A Traffic Forecasts

Table A.1: Massey Tunnel Replacement Traffic Forecasts

| Year | Car | Light truck | Heavy truck | Total truck | Total traffic |
|------|--------|-------------|-------------|-------------|---------------|
| 2005 | 79,030 | 3,740 | 2,520 | 6,260 | 85,280 |

5.2 Marine Use Assessment Highlights:

- The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, sorting and booming, as well as commercial, recreational, and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place in the vicinity of the Project.
- The proposed clear span crossing of the Fraser River will avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span, improving navigation in and out of the slough.
- Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.
- Working with Aboriginal Groups and key stakeholders to develop a Marine Access Management Plan will mitigate temporary impacts to marine use associated with Project construction.
- Key mitigation considerations to ensure marine use activities can continue in a safe manner during Project construction include:
 - Communications protocols to establish and advise of in-stream construction activities.
 - Lighting and marking for safe navigation.
 - Establishing navigation protection zones during construction to avoid or minimize impacts on marine use.

5.2 Marine Use

This section presents the assessment of potential effects of the Project on marine use and includes a description of existing conditions, potential Project-related effects including proposed mitigation measures, and an evaluation of residual Project-related and cumulative effects.

5.2.1 Context and Boundaries

This section describes the context for assessment of Project-related effects on marine use in terms of Project setting, and defines the spatial, temporal, administrative, and technical assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

5.2.1.1 Assessment Context

The Fraser River South Arm supports a variety of marine uses, including international and domestic shipping; commercial, recreational and Aboriginal (CRA) fishing; and recreational boating and moorage. Two recreational boat marinas and a rowing club are located along the south and east shorelines of Deas Slough with year-round water access.

Maintaining waterway navigation needs and access is important to the provincial and federal economies, Aboriginal Groups, many businesses, and the general public. In addition, the public's right to navigate the Fraser River South Arm is protected by the *Navigation Protection Act (NPA)*, R.S.C. 1987, c. N-22.

The Project will involve construction activities in the Fraser River South Arm and Deas Slough that may temporarily affect navigation, CRA fisheries, and other recreational boating. The Fraser River South Arm in the vicinity of the Project supports a variety of marine uses, and activities associated with Project construction may result in temporary changes to access and navigability in the vicinity of the Project.

Consultation with the public, Aboriginal Groups, and marine users informed the selection of Marine Use as a Valued Component (VC) for the assessment of potential effects of the Project. Changes in marine use and marine access were raised as areas of interest to local industry located along the Fraser River including port-related businesses that rely on marine access, Aboriginal Groups, and the general public during consultation. Additional information supporting the selection of marine use as VC is provided in **Section 3.1 Issues Scoping and Selection of Valued Components**.

5.2.1.2 Methodology

The assessment of marine use follows the general methodology described in **Section 3.0 Assessment Methodology** and is applied to all VCs. Building on this approach, the assessment of marine use focuses on the following sub-components:

- Commercial navigation
- Navigation for CRA fisheries
- Recreational navigation

Changes in access to, and within, the South Arm of the Fraser and changes in marine traffic (i.e., frequency and volume) that could affect navigability were selected as indicators to assess trends in marine use and to evaluate potential Project-related effects on commercial navigation, CRA fisheries, and recreational navigation.

Access to waterways is evaluated in terms of potential change in vessel access to or within the Fraser River South Arm as a result of construction or operation of the Project. Marine traffic frequency and volume is evaluated in terms of potential for increase in the number of vessels or equipment within the Project area that are directly associated with the Project. Evaluation of this indicator is therefore limited to the Project construction phase.

5.2.1.3 Assessment Boundaries

Spatial, temporal, administrative, and technical boundaries identified for the assessment of Project-related effects on marine use, and the rationale for selecting them are discussed below.

Spatial Boundaries

The local assessment area (LAA) and regional assessment area (RAA) for marine use are defined in **Table 5.2-1** and shown in **Figure 5.2-1**. The boundaries of the assessment area take into account the scale and spatial extent of potential environmental effects that are appropriate for the three marine use sub-components.

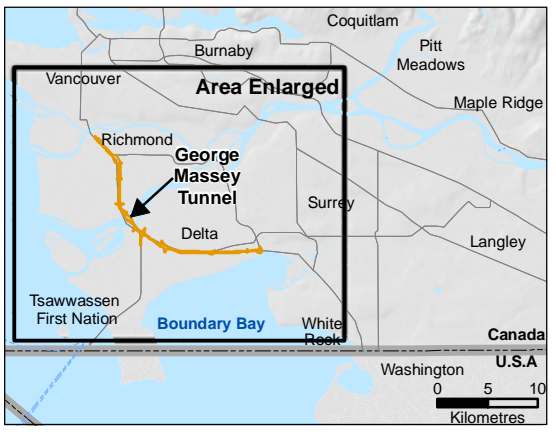

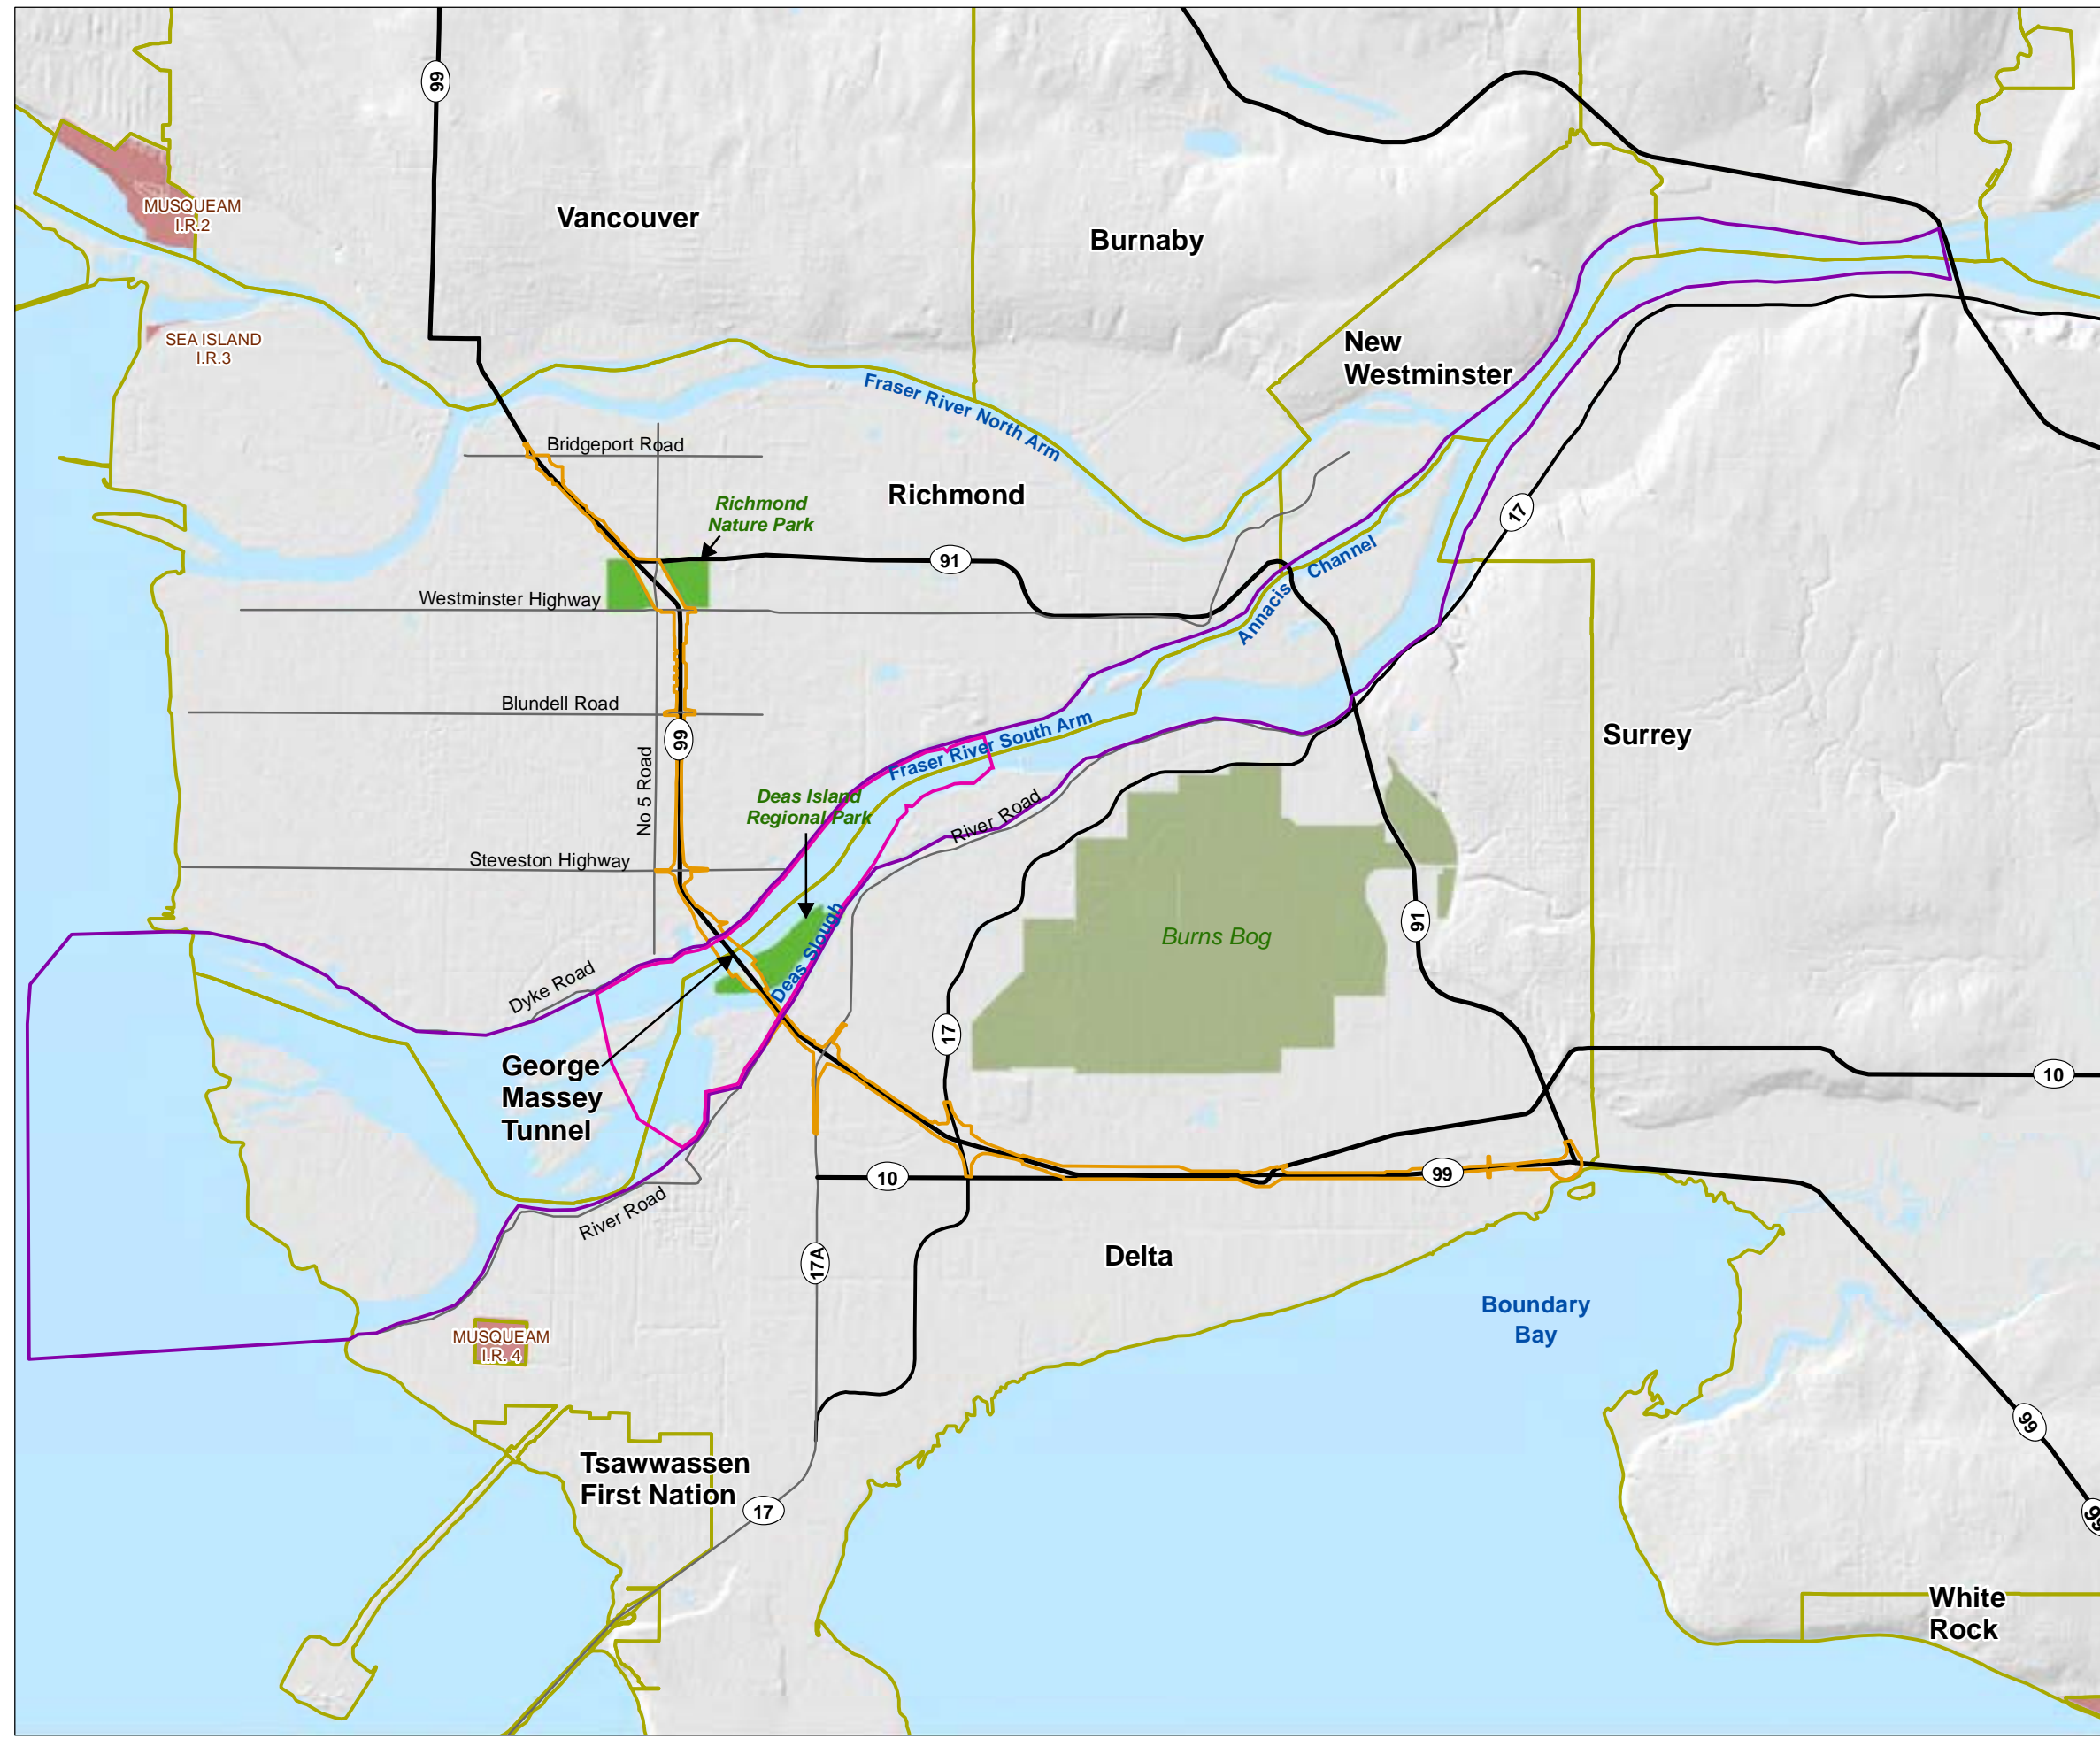

Table 5.2-1 Spatial Boundary for Marine Use Assessment

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|--|
| Local assessment area (LAA) | 2.5 km downstream and 5 km upstream of the Tunnel, in the Fraser River South Arm main channel, and 500 m on either side of the existing Deas Slough Bridge. |
| Regional assessment area (RAA) | Vancouver Fraser Port Authority (VFPA) Land Use Planning Area 5 (Fraser River Central, from approximately three kilometers southwest of the Alex Fraser Bridge) and Planning Area 7 (including only Fraser River South Arm, from approximately three kilometres southwest of the Alex Fraser Bridge to the river mouth). |

The LAA for marine use was established to encompass the area within which the Project is most likely to interact and potentially affect marine use. In determining the LAA boundary, consideration was given to the nature and characteristics of marine use, potential exposure to various influences (e.g., changes in river hydraulics and morphology following Tunnel removal), and the maximum extent of potential Project-related effects on marine use.

The RAA includes most of VFPA's Land Use Planning Area 5 and 7 (further discussed as a part of the administrative boundary below) and was established to provide a regional context in terms of marine use in nearby marine planning areas.

Temporal Boundaries

The temporal boundaries established for the assessment of adverse Project effects on marine use encompass the existing conditions, the Project construction phase (including decommissioning of the Tunnel and Deas Slough Bridge), and the Project operations phase (i.e., the new bridge and improvements in operation). Temporal characteristics of the Project's construction phase are defined in **Section 1.1 Description of Proposed Project**.

Administrative Boundaries

The assessment areas for the Project were selected based on the spatial extent of potential Project-related effects on marine use. The LAA and the RAA include the following administrative boundaries:

- The LAA overlaps two Fisheries and Oceans Canada (DFO) sub-areas in the Pacific Fisheries Management Area (PFMA) 29 (i.e., sub-areas 13 and 14). The RAA overlaps four sub-areas in PFMA 29 (i.e., sub-areas 9, 13, 14, and 17).
 - Sub-area 29-13 consists of the Fraser River South Arm from Steveston Island upstream to the Pattullo Bridge.
 - Sub-area 29-14 is south of sub-area 29-13 and consists of the waters south of the Woodward Island training structure from Reifel Island upstream to Deas Slough.
 - Sub-area 29-9 is downstream from sub-areas 29-13 and 29-14 and extends from the mouth of the Fraser River South Arm upstream to Reifel Island.
 - Sub-area 29-17 is upstream of sub-area 29-13 and consists of the Fraser River South Arm from the Pattullo Bridge to the Alex Fraser Bridge.
- The LAA is located within the VFPA Land Use Planning Area 7.
- The RAA is located within VFPA Land Use Planning Areas 5 and 7.
 - Planning Area 7 extends from the North Arm Jetty and Sturgeon Bank to the north end of Boundary Road in New Westminster, and from the Sand Heads to just east of Tilbury Island.
 - Planning Area 5 is upstream from Planning Area 7 and extends from approximately three kilometres southwest of the Alex Fraser Bridge on the south reach to west of the Port Mann Bridge.

Technical Boundaries

There were some limitations in availability of historic data on fisheries use and vessel activity as discussed in **5.2.2.1 Baseline Data Collection**; however, the Ministry's ongoing engagement with commercial, aboriginal, and recreational marine users has provided information to address such data gaps prior to undertaking the assessment of Project-related effects.

No other constraints such as accessibility or gaps in data that could limit the ability to predict the effects of the Project on marine use have been identified; therefore no technical boundaries were defined.

5.2.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data, and describes the existing conditions of marine use within the assessment areas. An overview of the regulatory context for management of marine use as relevant to the Project is also provided.

5.2.2.1 Baseline Data Collection

In 2014, the Ministry initiated a desktop review of marine use to support Project planning and assessment. Building on available information, the review was designed to address known data gaps, as summarized in **Table 5.2-2**, and described in further detail below.

Table 5.2-2 Marine Use Studies

| Study Name | Purpose of Study |
|--------------------------|--|
| Desktop Review | Understand the existing information available about marine use near the Project through a review of background information including reports and data. |
| Preliminary Consultation | Meet with key marine and water-based land users and agencies to discuss potential effects of the Project and understand interests. |

Desktop Review

Existing background information relevant to the Project, including the following, was assembled and reviewed:

- Relevant discussion on marine use issues, effects and mitigation from previous environmental assessment reports.
- Navigation and river use information, including:
 - Physical characteristics and navigability of the lower Fraser River and smaller channels
 - Marine and water-dependent land uses (e.g., deep sea berths, marinas, and vessel moorage)
 - Frequency of vessel use and vessel types navigating the lower Fraser River

- Publicly available fisheries information, including
 - Fraser River fisheries information (DFO 2013a), notices (DFO 2015), and First Nations catch reports (DFO 2014a)
 - Other sources of information (e.g., DFO harvesting statistics and fisheries management plans, VFPA Land Use Plan 2014) with respect to marine use within the LAA and RAA
 - Port of Vancouver’s Fraser River Tanker Traffic Study (DNV 2012)
- Relevant information regarding current and traditional fishing activities gathered from Traditional Use Studies and information provided by Aboriginal Groups during pre-Application consultation

Preliminary Consultation

Aboriginal Groups

Consultation with Schedule B Aboriginal Groups with respect to marine use began during the Initial Consultation Phase, is ongoing, and described in **Section 10.1.2 Consultation Activities**.

Schedule B Aboriginal Groups have raised concerns related to marine access during construction, including Tunnel decommissioning, and the Ministry is continuing to work with these groups to better understand how they would like to participate in the development and implementation of mitigation measures. For further analysis on potential Project-related effects on Aboriginal access, including fishing access, refer to **Section 10.1.3 Aboriginal Interests Assessment**.

Commercial/recreational marine users

Between May 2014 and June 2015, the Ministry met with key representatives of commercial and recreational marine users, and other stakeholders with specific interest in the Project and its potential influence on marine activity. Individuals and organizations likely to have a potential interest were identified based on the Ministry’s experience in consulting with marine user groups during planning and implementation of projects such as the Port Mann Highway 1 Improvement Project and the Pitt River Bridge & Mary Hill Interchange Project, and issues/interests identified during general consultation on these projects.

A total of four meetings, two each with specific focus on commercial use and recreational use, were held to review Project components and discuss potential effects of the Project.

Initial meetings, on May 26, 2014 and May 21, 2015, were held with marine users and other stakeholders with a specific interest in the use of the river and sloughs for commercial purposes. A total of 68 participants, representing 29 marine businesses: one terminal, a rescue group, a community group, BC Coast Pilots, Fish Safe BC, the Council of Marine Carriers (CMC, which represents over 25 local marine businesses), VFPA, and Transport Canada, were invited to, and attended, each meeting. Eighteen individuals attended the May 26, 2014 meeting, representing eight marine businesses, BC Coast Pilots, the terminal, Fish Safe BC, CMC, VFPA, and Transport Canada. Twenty-four participants attended the May 21, 2015 meeting, representing 13 marine businesses, BC Coast Pilots, the terminal, Fish Safe BC, CMC, VFPA, and Transport Canada.

A Project overview, including consultation to date, technical work underway, existing marine traffic patterns, Tunnel removal options, vertical and horizontal clearances, river hydraulics and next steps, was provided at each meeting. A question and answer session took place after each Project update, which included further discussion on Tunnel removal, bridge clearances, interchange replacements, time frames, river hydraulics and morphology, and current marine traffic information. The need for an established forum (Marine Users Group) for communications between marine users during construction was a key outcome of these preliminary meetings.

Meetings with recreational marine users and stakeholders were held on June 25, 2014 and May 21, 2015. A total of twenty individuals representing seven recreational businesses, six recreational groups, one rescue group, one community group and Transport Canada, were invited to both meetings. The June 25, 2014 meeting was attended by five individuals who represented one recreational business, one recreational group, the rescue group, and Transport Canada. Two individuals, both representing one recreational group, attended the May 21, 2015 meeting.

An overall Project update was provided at each meeting, followed by a question and answer session where the following aspects were discussed: height of the bridge over Deas Slough; importance of effective communication during construction, specifically in the context of regattas in Deas Slough; potential noise impacts and mitigation; influence on the Millennium Trail; and Captain's Cove Marina's new housing development and marine enlargement (250 to 350 dock slips). Participants expressed a key interest in waterway closures, equipment in the water, and safety.

Data Limitations

Fisheries Data

Fisheries and Oceans Canada's reporting structure of fishing vessel activity data presents certain limitations for analysis within the LAA and RAA. Fish harvesting data is publicly reported at the PFMA and PFMA sub-area levels. However, the PFMA sub-areas are relatively large; PFMA 29, which overlaps with the LAA, includes areas of commercial fishing activity (e.g., Roberts and Sturgeon banks, southeastern Strait of Georgia) other than the LAA, so data reported at this level have limits for interpreting existing conditions in the LAA. The PFMA sub-areas, however, are sufficiently small, such that LAA fishing activity can be reasonably determined from reviewing data reported at this level.

The marine use LAA traverses PFMA sub-areas 29-13 and 29-14. Although the boundaries of these PFMA sub-areas do not coincide with the LAA boundaries, they portray with reasonable accuracy fishing activity within the marine use LAA. Fisheries and Oceans Canada does not make the data collected on harvest activity publicly available when there are fewer than three vessels active on an annual basis in a PFMA sub-area.

Data on guided sport fishing activity is limited. Recreational fishing data from DFO are only available for areas larger than the PFMA sub-areas, and primarily reflect self-directed recreational fishing.

With respect to Aboriginal fisheries, publicly available information sources generally only listed the broad areas where fishing occurs (e.g., "below Port Mann Bridge"). For more specific information regarding Aboriginal fishing, particularly for domestic or food, social and ceremonial (FSC) purposes, see **Section 10.1.3 Aboriginal Interests Assessment**.

Vessel Movement Data

Vessel movement data may not fully account for all vessel traffic through the LAA. It is not mandatory for commercial vessels less than 20 m or pleasure yachts under 30 m to either participate in the Canadian Coast Guard vessel traffic services or install a satellite automatic identification system; therefore, small vessels may not be fully captured in the available vessel movement data.

5.2.2.2 Regulatory Context

Federal

Transport Canada

The *NPA*, administered by Transport Canada, protects the public's right to navigate waters of Canada, and regulates construction work on navigable waters. The Act requires an authorization to permit the construction or placement of work (i.e., structure, device, or thing, temporary or permanent, made by humans) in, on, over, under, through, or across scheduled navigable waterways. The Fraser River is a scheduled navigable waterway. Under the Act, a Notice to the Minister of Transport is required if the Project is "likely to substantially interfere" (Section 4, 6, 8, and 9 of the Act) with marine use. An approval must be obtained before construction of marine infrastructure associated with the Project. Approval will be subject to review of the final design, and may include stipulations for navigational safety.

VFPA maintains navigational jurisdiction in the Fraser River South Arm and is responsible for the maintenance of deep sea and domestic channels for navigation. Further, the VFPA has developed harbour operations, practices, and procedures pursuant to Section 56 of the *Canada Marine Act*, which apply to vessels in Port jurisdiction, including small craft vessels, as well as other users of the Port.

As the Project is not located on VFPA-administered federal land, it will not undergo a separate review under the VFPA's Project and Environmental Review (PER) process. VFPA will consider potential effects of the Project through participation in the Technical Working Group.

Fisheries and Oceans Canada

Regulation and management of CRA fisheries occurs through the *Fisheries Act*, which protects the ongoing productivity and sustainability of CRA fisheries. The lower Fraser River supports CRA fisheries, of which Pacific salmon and eulachon are managed by Fisheries and Oceans Canada (DFO). Licensing and regulation of fisheries authorized under the *Fisheries Act* are regulated by:

- *Fishery (General) Regulations*
- *Pacific Fishery Regulations, 1993*
- *Aboriginal Communal Fishing Licenses Regulations*
- *British Columbia Sport Fishing Regulations, 1996*
- *Pacific Fishery Management Area Regulations, 2007*

Pacific Pilotage Authority and the B.C. Coast Pilots

The Pacific Pilotage Authority's and the B.C. Coast Pilots' mandate is to provide safe, reliable and efficient marine pilotage and related services in the Coastal waters of B.C., including the Fraser River. Under the *Pilotage Act* every commercial vessel over 350 gross registered tonnes is required to utilize the services of a qualified and licensed marine pilot when entering B.C. waters. The Fraser River Pilots, responsible for piloting vessel traffic in the Fraser River, provide expert local knowledge and handling ability on the river.

Canada Shipping Act

Transport Canada administers the *Canada Shipping Act S.C. 2001 c. 26*, which is intended to promote safe marine transportation and recreational boating, protects the marine environment from damage due to navigation and shipping activities, ensures that Canada meets international obligations under bilateral and multilateral agreements with respect to navigation and shipping, and establishes an inspection and enforcement program. With respect to the Project, this Act applies to Canadian and foreign vessels navigating the Fraser River, with the exception of Canadian Forces vessels.

5.2.2.3 Existing Conditions

The existing conditions of the study area are described for each sub-component in the following sections.

Commercial Navigation

Hydrodynamic Conditions of the Fraser River

Navigation in the Fraser River South Arm is affected by river flow conditions. Water levels and tides, among others, are factors considered by Fraser River pilots when determining a vessel's passage plan through the Fraser River. Water levels and tides are affected by freshwater discharge; mainly snowmelt. Discharge typically rises in April, peaks between May and July during freshet, and recedes during autumn and winter.

Tides at the Fraser River mouth are mixed semi-diurnal with two highs and two lows per day, with a large diurnal inequality during spring tides. During the low flow months (i.e., September through April), the tides create alternating flood and ebb flows at the lower reach of the Fraser River. During freshet, flows are predominantly seaward, but can be checked or reversed by the flood tide.

Additional information on the hydrodynamic conditions in the Fraser River is described in **Section 4.1 River Hydraulics and River Morphology**.

Fraser River South Arm Navigation

The Fraser River South Arm is navigable by marine vessels from its mouth to Yale, approximately 175 km upstream; however, river depth limits the draft of marine vessels capable of navigating upstream of New Westminster and channel geometry limit the length of vessel that can practically be used on the Fraser River. The lower reaches of the Fraser River South Arm are dredged annually to maintain, with tidal aid, a water draft of 11.5 m for at least two hours per day, every day of the year, from the river mouth to Fraser Surrey Docks, approximately 30 km upstream.

Navigation channels are classified into three official channel types and one unofficial channel type known as a channel reserve. The officially designated channels have design parameters based on the types of vessels transiting the channels as well as the goods being transported through each navigation channel, specifically:

- Deep sea channel: a 200-m wide navigation channel maintained to service ocean going vessels
- Domestic channel: a navigation channel maintained to service barge and towboat industry, or the local coastal community
- Local channel: the portion of the waterway that is neither a deep sea channel nor a domestic channel, but is used by a variety of smaller operators

The deep sea channel is 322 m wide, comprising a 200-m navigation channel, and two 61-m safety zones on either side of the navigation channel. The VFPA maintains an 11.5-m water draft in the channel for two hours per day.

Deas Slough Navigation

Deas Slough is a local navigation channel approximately 50 m wide, with an average depth of 5 m. At the Deas Slough Bridge, vertical clearance of Deas Slough is approximately 2.5 metres at high water datum. Infrequent and localized dredging takes place to maintain access to small craft harbours and moorage (PMV 2015c).

Land Use Supporting Commercial Navigation Requirements

Approximately four per cent of upland waterfront sites along the shoreline of the Fraser River South Arm are administered by VFPA, while the bordering municipalities of Richmond, Delta, Surrey, and New Westminster regulate the remaining sites. Within these municipalities,

industrial lands along the Fraser River shoreline have access to the river and the deep sea channel. The VFPA has identified long-term trends in maritime commercial navigation including containerization and bulk shipping, and continues to focus on maintaining and growing commercial marine use. Existing land use along the Fraser River is supported by deep sea terminals, coastal shipping, port services and industry, water lots, and moorage.

There are three deep sea terminals operating along the Fraser River South Arm:

- Fraser Surrey Docks, located approximately 14 km upstream of the Project, is primarily a break bulk terminal that can also handle containers with six freight sheds, and six deep sea terminals. Principle exported commodities include pulp, paper, and lumber, while steel and general cargo are principle imports.
- Annacis Auto Terminals, located on Annacis Island approximately 14 km upstream of the Project, services auto transport. It includes two deep sea berths, and intermodal rail and truck loading facilities.
- Fraser Wharves, located on Lulu Island approximately 1.5 km upstream of the Project, also services auto transport. It includes one deep sea berth, and an intermodal rail truck loading facility.

Future land use planning in the RAA has been identified in the VFPA's 2014 Land Use Plan (PMV 2014c). VFPA holds a number of upland properties, and leases water lots to support trade activities within Planning Area 7 (which includes the LAA). Future use of these lands is likely to be similar to those now present, although more intensive use of the sites can be anticipated to support trade growth. Planning Area 5, located upstream of the Project, represents the main location of port activity in the Fraser River and includes Fraser Surrey Docks and Annacis Auto Terminals. This area will continue to be the main hub of shipping and goods movement in the Fraser River with anticipated intensification of use and growth in sectors including bulk, break-bulk, liquid bulk, and other commodities.

Marine Traffic and Activity

Over 170,000 reported vessel movements occur annually in the Strait of Georgia between the Strait of Juan de Fuca to the south and Ballenas Island to the north. The majority of vessel movements in B.C.'s coastal waters are passenger traffic and tug-and-barge traffic, representing approximately 56% and 29% of overall vessel traffic, respectively (B.C. MOE 2006). Deep-sea cargo vessel movements (i.e., tanker vessels, bulk cargo carriers, container ships) account for approximately eight per cent, and the remaining are fishing and other vessel traffic (B.C. MOE 2006).

Commercial marine activities are extensive in the lower Fraser River. In 2014, cargo tonnage handled exceeded 140 million metric tonnes, and included general cargo, aggregate, logs, wood chips, hog fuel, paper, steel, cement, and automobiles (PMV 2014a).

Thousands of vessels transit the Fraser River South Arm annually. Vessel traffic in the Fraser River South Arm was examined by Det Norske Veritas (DNV) as part of the VFPA’s Fraser River Tanker Traffic Study (DNV 2012). The study divided traffic in the Fraser River South Arm into nine segments between the mouth of the Fraser to Patullo Bridge. The Project lies within the segment which extends from approximately the western end of Kirkland Island, near the outlet of Finn Slough, to the northern end of Deas Island. Vessel traffic counts for this study were collected from Automatic Information System data.

Table 5.2-3 shows that there were an estimated 12,716 vessel movements (up and down river) on the Fraser River South Arm through the LAA between July 2010 and June 2011 (DNV 2012). Tug-and-barge and cargo ferries were the most frequent vessel movements, accounting for 48% and 36% of total traffic volume, respectively.

As shown in **Table 5.2-3**, within the LAA deep water vessel traffic accounted for 1,076 annual vessel movements up and down river. These vessel movements consisted of the following cargo types and associated number of vessel movements (DNV 2012):

- Auto carrier vessels carrying cars - 564 vessel movements
- Container vessels carrying mixed cargo - 240 vessel movements
- Break bulk vessels carrying steel and lumber - 200 vessel movements
- Dry bulk vessels carrying grain - 74 vessel movements

Table 5.2-3 Vessel Movements through the LAA (July 2010 to June 2011)

| Vessel Type | Number of Vessels Movements Up and Down River | Percentage of Movements (Number of Movements ÷ Total Traffic) |
|-------------------|---|---|
| Deep Water Vessel | 1,076 | 8% |
| Cargo Ferry | 4,576 | 36% |
| Dredger | 678 | 5% |
| Fishing | 50 | <1% |
| Passenger | 48 | <1% |
| Pilot Vessel | 2 | <1% |
| Pleasure | 102 | 1% |
| Sailing Vessel | 4 | <1% |

| Vessel Type | Number of Vessels Movements Up and Down River | Percentage of Movements (Number of Movements ÷ Total Traffic) |
|------------------------|---|---|
| Search and Rescue | 130 | 1% |
| Tug-and-Barge | 6,046 | 48% |
| Unspecified | 4 | <1% |
| Total Vessel Movements | 12,716 | 100% |

Note: Summary of upriver and downriver data modified from DNV 2012.

Future vessel traffic in the LAA has been identified in DNV’s Tanker Traffic Study (DNV 2012). With the exception of tug-and-barge traffic, the majority of the vessel traffic in the Fraser River South Arm is not anticipated to increase over the next ten years (DNV 2012). Tug-and-barge traffic is expected to increase at a nominal rate of 3% per year (DNV 2012).

Since the DNV 2012 report was completed, the estimate for anticipated vessel traffic in the LAA has been updated and now reflects an approximately 10% increase in deep water vessels and a less than 1% increase in barge traffic over the 2012 values.

Commercial, Recreational, and Aboriginal (CRA) Fisheries

Overview of Fisheries

Fraser River fisheries contribute significantly to the economic activity along the river (Richmond Chamber of Commerce and D.E. Park and Associates Ltd. 2014). The Steveston Harbour, approximately nine kilometres downstream of the Project, is the largest commercial fishing harbour in Canada, home to more than 350 commercial fishing vessels. Between 13 and 30 million kg of fish and seafood are unloaded at Steveston annually (Kiesman 2013).

Lower Fraser River fisheries openings are summarized in **Table 5.2-4**, and are discussed in the following sections. Data on commercial (including Aboriginal) fisheries openings is summarized for the period between 2004 and 2014 (DFO 2014a, 2015). Data for Aboriginal FSC fisheries openings (downstream of the Port Mann Bridge to the river mouth) is summarized for the period of 2004 to 2009, and the year 2013, and includes communal licences, communal licences with limited participation, and communal licences with allowance for sale (DFO 2014a). Coho salmon is not included in **Table 5.2-4**, reflecting non-retention and non-possession currently in effect for Fraser River fisheries (DFO 2012). Data on fisheries openings is expressed in number of hours per week and does not represent fishing effort or catch levels.

Notes: ■ Dark grey cells denote run timings for Pacific salmon and eulachon. Data shown for pink salmon represents odd years.
 Fishery openings are expressed in number of hours with a shading gradient transitioning from dark blue (representing greater number of hours) to light blue (representing fewer hours) per week.
 ▤ Crosshatched cells represent non-targeted fisheries (i.e., retention of a species is allowed during fisheries targeting another species).
¹ FSC: Food, social, and ceremonial Aboriginal fisheries; ² EO: Economic opportunity Aboriginal fisheries

Commercial Fisheries

Commercial salmon fisheries within the LAA (i.e., within PFMA sub-areas 29-13 and 29-14) are conducted primarily with gill nets (i.e., under DFO Salmon Area E Gillnet licences). Salmon gill net fisheries openings are relatively short, depending on run strength determined in-season (Table 5.2-4). Specific commercial management areas (Salmon Area E Gillnet, Salmon Area H Troll, and Salmon Area B Seine) apply to commercial salmon fishing activities in the lower Fraser River and are specified within fishing permits. These licences apply to all of Area 29 (as well as to PFMA areas beyond Area 29); however, within the Fraser River, these fisheries typically occur from the Port Mann Bridge downstream to the river mouth, and therefore overlap the Project area. Openings typically last from 3 to 24 hours, and may begin in mid-July through to mid-September and again in mid-October through to mid-November (Table 5.2-4). The number of gill net openings varies annually, typically between two and four openings per year,

with as many as 10 openings during years with peak salmon runs (DFO 2015). Commercial gill net fisheries target sockeye and chum salmon, but permit the retention of pink and chinook (DFO 2015).

Aboriginal Groups participate in commercial salmon fisheries in the lower Fraser River, both in the general commercial fishery and under communal commercial licences, deriving economic benefits from fishery revenues and employment-generated income. Aboriginal commercial harvest opportunities under communal commercial licences are managed using rules that are similar to those applied to general commercial fisheries (DFO 2014b). Schedule B Aboriginal Groups hold Salmon Area E Gillnet licences, and some are in the process of acquiring additional licences.. Commercial licences and businesses owned by Schedule B Aboriginal Groups are identified in **Section 10.0 Aboriginal Consultation** and includes information provided by Aboriginal Groups as well as that collected through publicly available sources.

The Musqueam Indian Band is involved in commercial fisheries through Salish Seas Limited Partnership, a business owned jointly with the Tsleil-Waututh Nation and Sliammon First Nation. Species harvested commercially through this enterprise include crab, prawn, halibut, and herring. Individual Musqueam members also hold commercial licences (PMV 2015). In 2013, 2014, and 2015, Musqueam were licenced to harvest crab (targeting Dungeness, graceful and red rock) within the Musqueam Crab Area and prawn in PFMA sub-areas 29-2, 29-3, and 29-4 throughout the year (DFO 2016). Musqueam have noted that they have over 60 registered fishing vessels that are used to exercise their fishing rights.

The Project area lies within Tsawwassen Territory, and is situated in or near several harvesting areas defined in the Tsawwassen First Nation Final Agreement relating to fishing. The Tsawwassen First Nation Harvest Agreement provides for an annual commercial allocation of Fraser River sockeye, chum, and pink salmon (odd years only). These commercial allocations vary with the size of the Canadian Commercial Total Allowable Catch (TAC) for sockeye and pink salmon and the Terminal Commercial Catch for chum salmon (TFN 2015). In 2013, there were seven openings for these purposes for pink salmon in September, and two openings for chum salmon in late October. In 2014, there were nine commercial openings for sockeye salmon in August and September, and two openings for chum salmon in late October. There were also two commercial openings for chum salmon in late October 2015 (DFO 2016). The Tsawwassen First Nation Harvest Agreement is also supported by the Tsawwassen Commercial Fish Fund and Tsawwassen Commercial Crab Fund, the monies from which are used to secure general commercial licences for salmon or crab for conversion to Tsawwassen First Nation Harvest Agreement licences (PMV 2015a).

The Hul'qumi'num Fisheries Limited Partnership (HFLP) is a commercial fishing business in which Cowichan Tribes, Halalt First Nation, Penelakut Tribe, Stz'uminus First Nation, Lake Cowichan First Nation and Lyackson First Nation are affiliated. Species harvested through this enterprise are crab (one Area H licence), prawn (two local / coast wide licences), halibut (one licence and annual TAC quota), herring (13 gillnet and 1 seine), rockfish (two Area Inside licences, targeting yelloweye, quillback, copper, china, and tiger), sablefish (annual TAC quota), and salmon (five Area E gillnet licences) (HFLP 2014). Commercial fisheries for halibut and sablefish are generally undertaken off the west coast of Vancouver Island (PMV 2015, LFN 2016).

As recently as 2014, Katzie and other Lower Fraser First Nations, participated in an economic opportunity fishery for sockeye, of which Katzie are said to have had a share of 10,000 sockeye that could be sold (Melnychuk 2014).

Until the early 1990s, no directed net fisheries on coho or chinook were conducted in the Fraser River; however, these species, as well as steelhead, were harvested incidentally in the sockeye, pink, and chum salmon fisheries (B.C. MELP and DFO 1998).

A commercial eulachon fishery in the Fraser River was suspended in 1997 due to conservation concerns for the status of the stock and the inability to control fishing effort (DFO 2013b). Only a very small Aboriginal ceremonial fishery continues to the present (Schweigert et al. 2012).

Since 1994 a commercial sturgeon fishery in the lower Fraser River no longer exists, but until 1994, white sturgeon were retained as bycatch (caught unintentionally) in the salmon gill net fishery and sold commercially. Since 1994, commercial gill net fisheries are no longer permitted to take sturgeon, and Aboriginal Groups are discouraged from taking sturgeon (Fraser River White Sturgeon Working Group 2009).

Recreational Fisheries

Recreational fishing occurs within the lower Fraser River to provide food for personal use, as a leisure activity, or both. Recreational fishing is undertaken with a sport fishing licence. Fishing techniques within the lower Fraser River include trolling, mooching, and casting from boats, piers, or the shore, using bait, lures, or artificial flies. Casting from shore appears to be most prevalent. Recreational fisheries primarily target salmon (typically retention fisheries), and sturgeon (catch and release). Access to fishing along the lower Fraser River shoreline is possible from recreational parks (e.g., Deas Island Regional Park in the vicinity of the Project), piers, floating docks, boat launches (e.g., Ladner boat launch at the mouth of Deas Slough), and private and public marinas (e.g., Captain's Cove and the River House marinas in Deas Slough).

In the immediate vicinity of the Project, fishing from the river's riprap shoreline for pink salmon (during odd years) using hook and line is a popular recreational activity. The lower Fraser River, especially the river mouth, is a guided sport fishing destination, particularly during sockeye salmon runs. No recreational salmon catch data is available for the Fraser River South Arm in the vicinity of the Project.

Aboriginal Fisheries

Aboriginal Groups participate in domestic and FSC fisheries in the lower Fraser River in the vicinity of the Project. In general, DFO manages Aboriginal fisheries to provide access for food, social, and ceremonial (FSC) purposes. Aboriginal Groups that participate in domestic and FSC fisheries in the lower Fraser River in the vicinity of the Project are described in detail in **Section 10.1.3. Aboriginal Interests Assessment**. Information on relevant past, present, or desired future marine activities, including fishing access and methods have been gathered through consultation activities and publicly available sources and therefore may not necessarily reflect all current or desired future commercial, domestic, or FSC fisheries uses of all Schedule B Aboriginal Groups. More detail on traditional, historical, and current fishing and Aboriginal Interests within the Fraser River South Arm is provided in **Section 10.1.3 Aboriginal Interests Assessment**

FSC fisheries take priority over other uses, including other fisheries, after conservation targets have been met. The primary method of fishing for FSC purposes in the Fraser River is by use of drift gill nets.

Salmon fisheries for domestic or FSC purposes target all five species of Pacific salmon and occur throughout the lower Fraser River, primarily using drift gill nets. Aboriginal drift gill net fisheries are normally conducted on weekends from Friday through Sunday. Openings range from two hours to multiple days, between early March and late December, with peak efforts coinciding with the run timing of targeted species. In general, periods with the most openings occur during June, August, and October through November (**Table 5.2-4**; DFO 2013a).

Aboriginal harvesting of eulachon for domestic or FSC purposes in the lower Fraser River is authorized by communal licenses, issued for small amounts of eulachon on a case by case basis. Due to the limited nature of this fishery, fishing times are restricted to one day per year for each communal licence, and participants are required to report catches to DFO (DFO 2013c).

Cowichan Nation Alliance

Cowichan Nation Alliance historically harvested sockeye and pink salmon, sturgeon, shellfish, and marine mammals within the South Arm of the Fraser River. Cowichan Nation Alliance has previously reported that now filled-in sloughs and streams in or near Highway 99 once supported coho and eulachon, which were also harvested while they were resident on the Fraser River. *Tl'uq̓tinus* was used seasonally for harvesting purposes. Areas within the wider Fraser River estuary were also utilized by *Hul'q'umi'num'*-speaking peoples for fishing salmon, sturgeon, groundfish, and other marine resources on the foreshore (e.g., Tsawwassen, Point Roberts, Boundary Bay). Certain species (e.g., sockeye and pink salmon, sturgeon, eulachon, trout, flounder) could only be obtained in, or were preferred to be taken at, Fraser River-based locations. Member First Nations of the Cowichan Nation Alliance have been attempting to restore former fisheries within the Fraser River through Fisheries and Oceans Canada (DFO). Access to sockeye for member First Nations is said to be provided by DFO annually in Johnstone Strait and “off the mouth of the Fraser River”. In the vicinity of the Project area, however, access has been subject to negotiations with First Nations local to the lower Fraser River, and has been limited, occurring only in 2005, 2006, and 2008. In those years, the specific locations in the South Arm in which member First Nations of the Hul'qumi'num Treaty Group fished for food, social, and ceremonial (FSC) purposes under communal licences was below the Port Mann Bridge generally, as well as specifically, on some occasions, below the easterly point of Kirkland Island (i.e., downstream of the Project area). The Cowichan Nation Alliance has stated that it is in ongoing, active litigation over its asserted fishing rights on the South Arm of the Fraser River.

Katzie First Nation

Currently, Katzie are among the numerous First Nations involved in the Lower Fraser River salmon fishery under food, social and ceremonial (FSC) licences issued by Fisheries and Oceans Canada (DFO). Of the 570 registered members of Katzie, roughly one third of those members is reportedly licenced to fish during openings on the Fraser River, and an estimated 120 Katzie vessels use the Fraser River to harvest fish annually. Their fishing area is in the vicinity of their communities. Since 2004, Katzie appear to have been licensed to fish in this area for Chinook, sockeye, and chum salmon, steelhead, and eulachon, as well as for chum salmon specifically in the Pitt River, although the targeted species, timing, and frequency have varied year over year. In 2015, Kwantlen had opportunities to harvest salmon from the Fraser River under FSC communal licences, limited participation (i.e., ceremonial) licences, and economic opportunity licences. Communal licences appear to have been issued only for Chinook salmon, over three days in September, while limited participation licences were

issued for Chinook and chum salmon for a portion of one day each, in April and November, respectively, and eulachon on four occasions in April. Kwantlen consider the vitality of the Fraser River and its resources to be an important element of their culture. Salmon was and remains a primary resource and is the basis of Kwantlen’s economy.

Kwantlen First Nation

Kwantlen First Nation consider the vitality of the Fraser River and its resources to be an important element of Kwantlen culture. Salmon was and remains a primary resource and is the basis of Kwantlen’s economy. Kwantlen are among the numerous First Nations involved in the Lower Fraser River salmon fishery under food, social and ceremonial (FSC) licences issued by Fisheries and Oceans Canada (DFO). Kwantlen are typically licenced to fish for FSC purposes in the stretch of the Fraser River between the Port Mann Bridge and Mission, using both drift and set nets (DFO 2016); and appear to fish in this area for Chinook, sockeye, and chum salmon and eulachon.

Lake Cowichan First Nation

Lake Cowichan followed a seasonal round of resource use and regional settlement. Within this round, the Fraser River estuary has been described as the “most important economically”. Species harvested historically on the South Arm of the Fraser River included salmon, sturgeon, eulachon, shellfish, and marine mammals (particularly seals). Access to sockeye for Hul’qumi’num Treaty Group member nations for food, social, and ceremonial (FSC) purposes is said to be provided annually by Fisheries and Oceans Canada (DFO) in Johnstone Strait and “off the mouth of the Fraser River”. In the vicinity of the Project area, however, access has been subject to negotiations with First Nations local to the lower Fraser River, and has been limited, occurring only in 2005, 2006, and 2008.

Lyackson First Nation

The Fraser River, from its mouth up to Seabird Island (east of Chilliwack), has been described as a key fish and shellfish harvesting area for Lyackson, with Canoe Passage (*Hwlhitsu’um*) identified as particularly important for salmon fishing. Areas within the wider Fraser River estuary were also utilized by *Hul’q’umi’num’*-speaking peoples for fishing salmon, sturgeon, groundfish, halibut, and other marine resources on the foreshore. Lyackson First Nation has said that the mouth and South Arm of the Fraser River is currently the source of over 50% of their current subsistence salmon catch; however, they say fishing in the Fraser River area has become largely unavailable to them due in part to low present-day fish populations and the cost of boats and technology.

Musqueam Indian Band

Musqueam has an established right to fish for food, social, and ceremonial purposes in the area of Canoe Pass on the South Arm of the Fraser River pursuant to *R. v. Sparrow* [1990], 1 S.C.R. 1075 (SCC 1990). The Project area lies immediately upstream of this area, and within the area where this right is considered by the Ministry to be asserted. Musqueam also assert an Aboriginal right to fish for food, social and ceremonial purposes in a broader area that includes, but is not limited to, all waters of the Fraser River – including its North Arm, Middle Arm, and South Arm – downstream of the Port Mann Bridge to the Strait of Georgia. All five species of Pacific salmon, steelhead, rockfish (rock cod, red snapper), herring and herring spawn, smelt, halibut, eulachon, trout, and sturgeon were fished historically by the Musqueam in their traditional territory, and all were important economically. The most commonly harvested marine mammals included harbour seal, sea lion, and porpoise; harvesting areas included the Fraser River estuary. At productive beaches within Musqueam traditional territory, abalone, barnacles, clams, chitons, cockles, mussels, crabs, crayfish, octopus, oysters, prawn, scallops, sea urchins, sea cucumber, shrimp, and seaweed were harvested and set aside for winter supplies; however, clams were the most abundant and heavily harvested, including at Boundary Bay. Fishing remains central to Musqueam, and they have specified that the waters outside Steveston, Canoe Passage, and the lower of the Fraser River, and Roberts Bank are their most intensive salmon harvesting areas. Salmon is a key species to the Musqueam, important for FSC and economic purposes.

Hwlitsum

Hwlitsum followed a seasonal round of resource use and regional settlement that involved spending winter on the Gulf Islands and southern part of Vancouver Island (December to February) and summer on the Lower Mainland (March to November) (HFN 2016a). While part of their salmon fishing season was also spent at *Tl'uq̓tinus* (BC and PMV 2012), all species of salmon, cutthroat, Dolly Varden, dogfish, flounder, steelhead, smelt oysters, crab, sturgeon, eulachon, and trout are or have been obtained by Hwlitsum at Canoe Pass or at nearby locations, such as Kirkland Island (salmon), Cohilakthan Slough (steelhead and salmon), Steveston (eulachon, up to the Highway 99 crossing), Ladner Reach (crab), and Roberts Bank (crab and sockeye) (HFN 2016a; PMV 2015). Salmon, steelhead, trout, and sturgeon were also taken further up the Fraser River and its tributaries. Areas within the wider Fraser River estuary were also reportedly utilized by Hwlitsum for fishing salmon, sturgeon, groundfish, and other marine resources (e.g., Tsawwassen, Point Roberts, Boundary Bay) (HFN 2016a). Hwlitsum have said that access to and use of Fraser River resources has and remains aided by physical presence, including “a set of houses, two wharves and two net sheds” on or near Canoe Pass,

as well as through kinship ties with other First Nations (HFN 2016a); however, other sources suggest that Hwlitsum do not currently have a communal licence to fish in the Fraser River for food, social and ceremonial (FSC) purposes, and that their access to their FSC allocation must be gained through negotiations with First Nations with a communal licence (Cohen Commission 2011). Hwlitsum harvest crab and bivalve species such as clams (i.e., butter, manila, and littleneck), cockles, mussels, oysters, and abalone in the Gulf Islands. Shrimp are generally harvested throughout the Strait of Georgia (between the Gulf Islands and the Lower Mainland), as well as immediately west of the existing Roberts Bank terminals, with targeted shrimp harvesting at Sturgeon Bank. Other marine invertebrates taken include red and green sea urchin, octopus, squid and sea cucumber, all harvested on the western side of the Strait of Georgia (PMV 2015).

Semiahmoo First Nation

Semiahmoo has reported that they once fished for salmon, sturgeon, halibut, eulachon, herring, smelts, sea mammals (including hair seals, sea lions, and porpoises), and a range of beach foods. Semiahmoo said that they practiced their fishing rights in the Fraser River in the summer season at *Tl'ektines*, in the vicinity of the north end of the George Massey Tunnel. Shellfish were also important to the Semiahmoo, and Boundary Bay has been characterized as formerly one of the most productive shellfish harvesting locations on the Pacific coast. Semiahmoo reports that sturgeon and eulachon once served as an important substitute for other fisheries; however, current conservation measures prohibit retention of these species.

Squamish Nation

While Squamish Nation territory reportedly extends south as far the South Arm of the Fraser River, Squamish Nation do not currently fish directly in the Fraser River for food, social or ceremonial (FSC) purposes based on information previously reported by Squamish Nation (SN 2014) and a review of Fisheries and Oceans Canada (DFO) records regarding “Lower Fraser River Fisheries” from the last few years (DFO 2016).

Tsawwassen First Nation

Tsawwassen report that they actively fish in the South Arm of the Fraser River and within the Project area, and that portions of the Project occur within the two subareas 29-13 (Canoe Pass to Deas Island) and 29-14 (Steveston to Pattullo Bridge) (TFN 2015). Canoe Pass and the waters in and around Rose-Kirkland Island (i.e., Ladner Reach, Woodward Reach), which lie about 1 km downstream of the Project area, have been previously described as particularly important fishing areas (VAFFC 2011, BC and PMV 2012). The right to harvest fish allows

designated members of the Tsawwassen First Nation to exercise the right for domestic purposes and to trade or barter those fish among themselves or with other Aboriginal people resident in BC (TFN et al. 2009a, Chapter 9). Domestic allocations for sockeye, chum, pink, chinook, and coho salmon, which are centrally important to the Tsawwassen First Nation, are calculated using formulas described in the TFNFA; generally, set at 625 Chinook, 15,226 sockeye, 2,500 pink (odd years only), 500 coho, and 2,576 chum (TFN et al. 2009b, Appendix J-2).

In 2015, Tsawwassen First Nation fished under communal licence for chinook, sockeye, and chum salmon. Fraser River eulachon are fished in Canoe Passage in limited quantities (up to 50 lbs (23 kg) on average) for specific domestic purposes, typically in April and May, and only after conservation goals have been met. Tsawwassen report that eulachon, once very abundant, in particular in Canoe Passage, is now only available for distribution to Elders.

Canoe Passage was once a key sturgeon harvesting area, but now sturgeon cannot be kept due to conservation concerns. Groundfish may also be harvested year-round for domestic purposes under the TFNFA, but this harvest has not occurred since the TFNFA came into effect. Since the TFNFA came into effect, four to five licences have been issued for the domestic crab harvest, targeting Dungeness, graceful, and red rock species; domestic harvests of crab are currently not subject to allocation limits and are permitted throughout the year.

Tsleil-Waututh Nation

Marine resources were and remain central to Tsleil-Waututh for subsistence and cultural life. Salmon was a food staple, supported by the harvest of the full range of shellfish, including bivalves and crustaceans, sturgeon, a variety of groundfish, eulachon, herring, and smelt, as well as aquatic plants, such as seaweeds. Seals, porpoises, and sea lions were also harvested. Tsleil-Waututh report they hold a close cultural and spiritual connection to salmon (TWN 2015). Tsleil-Waututh reports that they have an extensive Fraser River sockeye fishery each year. The largest fishing effort occurs in August. Tsleil-Waututh has also participated in, and continues to “reserve the right,” to a limited participation fishery for ceremonial purposes outside of the regular Tsleil-Waututh sockeye fishing season (TWN 2016).

Fraser River sockeye remain a primary traditional food source for Tsleil-Waututh families, and salmon, herring, and crab are among the species that still contribute to the contemporary economy of Coast Salish peoples (TWN 2015). Sturgeon, due to its decline, is no longer a component of Tsleil-Waututh diet. It is Tsleil-Waututh’s goal to participate in the recovery of these species and their habitats for future generations (TWN 2015).

Tsleil-Waututh may fish for FSC purposes under communal licences issued by DFO. In addition to communal licences issued by DFO, Tsleil-Waututh report that they may access food fish through other means, such as through cultural protocols and kinship ties with neighbouring communities, when DFO communal licences are unavailable to Tsleil-Waututh.

PFMA subareas to TWN FSC licences currently apply include 28-11, 28-12, 28-13, 28-14, 29-3, 29-4, 29-6, 29-7, 29-9, 29-10, 29-11, 29-12, 29-13, 29-14, and 29-17 (DFO and TWN 2013). Subareas within PFMA 28 apply to eastern Burrard Inlet and Indian Arm; the other subareas within PFMA 29 cover the Fraser River downstream of the Port Mann Bridge and into the Strait of Georgia (DFO 2016). Subareas 29-13 and 29-14 overlap the Project corridor. Tsleil-Waututh also report having access to PFMA 29 for communal crab licences, and have been working with DFO through an access request process to recognize the entirety of PFMA 28 and PFMA 29 for prawn and crab communal fisheries in the Tsleil-Waututh Nation's CFA (TWN 2016). TWN's access to Fraser River salmon extend beyond sockeye and include pink, chum, chinook, and coho (incidental). In addition to communal FSC access, TWN holds 10 to 15 Allocation Transfer Program (ATP) communal commercial fishing licenses. This includes two crab, 4 to 9 herring gill net licenses, one prawn, and three salmon gill net licenses.

TWN is also involved in commercial fisheries through Salish Seas Limited Partnership, a business owned jointly with Musqueam Indian Band and Sliammon First Nation. Species harvested commercially through this enterprise include halibut, sablefish, prawn, crab, herring, and salmon.

Recreational Navigation

The Fraser River is important for a wide range of water-based recreation (Environment Canada 1994), with the type of activity varying by location. Activities undertaken within the Fraser River include fishing, waterskiing, motor-boating, canoeing, sailing, windsurfing, river rafting, and kayaking.

Recreational boating is prevalent throughout the LAA. Marine use in Deas Slough is dominated by recreational vessels with recreational water-sports including pleasure boating, paddle sports (kayaks, dragon boats, rowing shells, canoes), and waterskiing. Metro Vancouver manages recreational use of the slough year-round to ensure that paddle sports use the slough at separate times from water skiers by establishing a recreational uses schedule (Metro Vancouver 2016).

Two marinas (i.e., River House marina and Captain's Cove marina) occupy approximately one-third of the shore of the slough's south bank. River House marina is located north of Deas Slough Bridge and has 140 boat slips. Captain's Cove marina is located south of Deas Slough Bridge and has 350 boat slips. Boat slips are used year-round, however, usage increases in summer and decreases in winter.

In addition to the two marinas, the Delta Deas Rowing Club is located along the shoreline at the upstream end of slough, near the north end of Deas Island, within Deas Island Regional Park. Rowing from this club takes place within Deas Slough and the rowing club operates year-round.

A boat ramp, operated by the Corporation of Delta Parks and Recreation Department, provides public access to Deas Slough and the Fraser River South Arm. The boat ramp is located at the northern end of Ferry Road, immediately west of Captain's Cove marina. Dredging was initiated in February 2014 in lower Deas Slough to re-establish the depth and width of the local channel, and to remove materials around the Ferry Road boat ramp that had been affecting recreational boating activity (PMV 2014b).

5.2.3 Potential Effects

This section discusses potential interactions of Project components and activities with marine use, and potential effects of such interactions on commercial navigation, CRA fisheries, and recreational navigation. Changes in marine use are of interest to local industry located along the Fraser River including port-related businesses that rely on marine access, Aboriginal Groups, and the general public. Potential effects on marine use have been identified through consultation with potentially affected marine users, publicly available information sources, and experience gained by the Ministry in addressing marine use considerations on other projects (i.e., construction of the new Port Mann Bridge). Information on mitigation of potential effects, including Project design measures to avoid adverse effects, is provided in **Section 5.2.4**. Potential residual effects (i.e., effects remaining following the implementation of mitigation measures) are described in **Section 5.2.4**. A discussion of potential cumulative effects on marine use is presented in **Section 5.2.6**.

For further analysis of potential Project-related effects on Aboriginal Interests, including fishing, and measures to address those potential effects, see **Section 10.1.3 Aboriginal Interests Assessment**.

5.2.3.1 Project Interactions

An overview of potential interactions between Project activities and marine use during the construction and operation of Project components is provided in **Appendix A**. A preliminary evaluation of the potential effects of Project interactions on marine use, intended to focus the assessment on those interactions of greatest importance, is presented below. Interactions rated as having no effect are not considered further in the assessment.

Project-related construction activities in the Fraser River South Arm that have the potential to affect access to waterways include marine-based equipment working in or transiting the Project area and marine-based construction activities including Tunnel decommissioning.

Project-related construction activities that have the potential to affect the frequency and volume of marine traffic in the Project area include marine-based equipment working within the Fraser River South Arm or Deas Slough and marine-based equipment transiting through the Fraser River South Arm or Deas Slough. **Construction:** Construction of the new clear span bridge and Tunnel decommissioning has the potential to temporarily affect marine use in the Fraser River South Arm, including commercial navigation, navigation for CRA fisheries, and recreational navigation. Marine-based equipment will transit the Project area and, in some cases, will remain in the Project area in order to undertake construction activities including bridge construction and Tunnel decommissioning. Both the transit of marine-based equipment and the presence of such equipment to support construction activities could affect marine use during Project construction and Tunnel decommissioning activities.

Marine-based equipment is expected to include tug and barges used to support transporting construction materials including bridge components as well as Tunnel segments. More detail on the Project components and associated construction activities is provided in **Section 1.1 Description of Proposed Project** of the Application. Project construction is also assumed to require marine-based equipment to support localized instream work along the edge of Deas Slough and removal of Deas Slough Bridge and in-stream works associated with Tunnel decommissioning. Project-related construction activities in Deas Slough that have the potential to affect access to marine use include bridge foundation installation in localized areas along Deas Slough, overhead construction of the clear span over Deas Slough and removal of the Deas Slough Bridge. These activities could temporarily affect navigation for CRA fisheries and recreational navigation. Activities associated with decommissioning of Tunnel are expected to result in temporary impacts to CRA fisheries and recreational navigation.

Operation: The new crossing will be a clear span bridge, with support towers located on land, thereby avoiding effects on the river mainstem. Navigation clearances associated with the new bridge have been established with VFPA taking into account long-term marine use considerations and Transport Canada requirements. Interactions between the Project and marine use in the Fraser River South Arm during operation are not anticipated.

Removal of the Deas Slough Bridge will eliminate structures in the slough that currently infringe on the local navigation channel. The current available air draft of approximately 2.5 metres will be increased to approximately 20 m. The existing three span bridge will be replaced by a single, longer span structure. Interactions between the new bridge and marine use in Deas Slough during operations are anticipated to be positive.

5.2.3.2 Potential Effects

Construction:

During the construction of the new bridge, decommissioning of the Tunnel, foundation construction along the edge of Deas Slough and removal of the existing Deas Slough Bridge, interaction between the Project and marine use will be managed to ensure safety and to maintain the navigation needs and marine use of the river and Deas Slough.

As described in **Section 1.1.7 Project Activities by Phase**, construction of the new bridge is assumed to involve lifting of pre-fabricated deck segments from barges in the river followed by the sequential connection of each segment to cables suspended from the land-based towers. When the central segments of the bridge deck need to be installed, a temporary, one-directional navigation would allow construction and marine traffic to proceed safely. A similar approach could be used for Tunnel removal as described in **Section 1.1.7 Project Activities by Phase** when barge-based equipment will need to be located over the four central segments of the Tunnel to remove them.

Either barge or land based equipment will be required to install the stone columns and piles along the edge of Deas Slough. In addition, construction over top of Deas Slough to construct the south approaches to the new bridge and barge-based work to remove the existing Deas Slough Bridge will be required. Transiting of recreational vessels under the Deas Slough Bridge will be temporarily affected by these operations.

Commercial Navigation

Change in Access

During construction activities based within the Fraser River South Arm, some commercial navigation may be temporarily affected by the requirement to establish a temporary, one-directional navigation channel to allow construction and marine traffic to proceed safely.

This requirement may result in a temporary infringement on access for some vessels, including those requiring the maximum draft, where such vessels would have a smaller timing window during which they would be able to move through the Project area. Smaller vessels, with a reduced draft requirement, would be less affected by this restriction. Full closures of the deep water navigable zone are expected to be limited and undertaken with substantial advanced notice.

Change in Marine Traffic Volume and Frequency

While the use of marine-based equipment will be limited to the extent possible, where possible and practical, bridge construction and Tunnel decommissioning will result in temporary increases in the volume and frequency of marine-based vessels transiting the Fraser River South Arm. These anticipated increases in the volume and frequency of marine traffic may result in temporary effects on navigability within the Project area.

Commercial, Recreational, and Aboriginal (CRA) Fisheries

Change in Access

During construction activities taking place within the Fraser River South Arm, navigation for CRA fisheries may be temporarily affected by the requirement to establish a temporary, one-directional navigation channel to allow construction and marine traffic to proceed safely.

While this requirement may result in a temporary infringement on access for some vessels, including those requiring the maximum draft, it is assumed that vessels used to support CRA fisheries, which would have a reduced draft requirement compared to larger commercial vessels, would be less affected by this infringement.

In addition to temporary infringements on access to the main stem of the Fraser River South Arm, construction activities within or along Deas Slough may result in temporary infringements on access to these areas.

Full closures of the deep water navigable zone of the Fraser River South Arm and full closures of Deas Slough are expected to be limited and undertaken with substantial advanced notice.

Change in Marine Traffic Volume and Frequency

While the use of marine-based equipment will be limited to the extent possible, where possible and practical, bridge construction and Tunnel decommissioning will result in temporary increases in the volume and frequency of marine-based vessels transiting the Fraser River South Arm. These anticipated increases in the volume and frequency of marine traffic may result in effects on navigability support CRA fisheries within the Project area.

Recreational Navigation

Change in Access to Waterways

During construction activities taking place within the Fraser River South Arm, recreational navigation may be temporarily affected by the requirement to establish a temporary, one-directional navigation channel to allow construction and marine traffic to proceed safely.

While this requirement may result in a temporary infringement on access for some vessels, including those requiring the maximum draft, it is assumed that smaller recreational vessels, which would have a reduced draft requirement compared to larger commercial vessels, would be less affected by this infringement.

In addition to temporary infringements on access to the main stem of the Fraser River South Arm, construction activities within or along Deas Slough may result in temporary infringements on access to these areas.

Full closures of the deep water navigable zone of the Fraser River South Arm and full closures of Deas Slough are expected to be limited and undertaken with substantial advance notice.

Change in Marine Traffic Volume and Frequency

While the use of marine-based equipment will be limited to the extent possible, where possible and practical, bridge construction and Tunnel decommissioning will result in temporary increases in the volume and frequency of marine-based vessels transiting the Fraser River South Arm. These anticipated increases in the volume and frequency of marine traffic may result in effects on navigability for recreational navigation within the Project area.

Operation

Change in Access to Waterways

Given that the Reference Concept includes a clear span over the Fraser River and Deas Slough, Project-related effects to marine use in the Fraser River South Arm are not anticipated during operation. Vertical and horizontal clearance dimensions of the navigation channel of the Fraser River crossing will be similar to those at the Alex Fraser Bridge and have been established in consultation with VFPA. The Project is not expected to result in a change in marine access in the Fraser River South Arm during Project operation.

The Project will improve navigation opportunities within Deas Slough during operation. Removal of the Deas Slough Bridge, including removal of in-water piers and replacement of the existing three span bridge with a longer single span, will eliminate structures in the slough that currently constrain the local navigation channel. The current available air draft of 2.5 metres will be increased to approximately 20 m. The horizontal clearance available for navigation at Deas Slough will be increased with the provision of a clear span. This is considered to be a positive change in marine access within Deas Slough.

Change in Marine Traffic Frequency and Volume

The temporary increase in marine-based traffic associated with the Project will be limited to the construction phase (i.e., bridge construction and Tunnel decommissioning). No Project-related marine-based vessels or equipment within the Fraser River South Arm or Deas Slough during Project operation. As such, changes in marine traffic frequency and volume are not expected during Project operation.

5.2.4 Mitigation Measures

5.2.4.1 Avoidance

Navigation clearances for the new bridge have been established in consultation with the VFPA and Transport Canada and match the navigation clearance envelope provided by the upstream Alex Fraser Bridge (**Appendix 16.1 Reference Concept**). The vertical clearance of the new bridge in the Fraser River South Arm will provide:

- 57 m above high water at 2.0 m high water datum (GSC) for a two-directional, 200-m wide channel
- 59.6 m above high water at 2.0 m high water datum (GSC) for a central, one-directional, 130-m wide channel

Horizontal clearance of the new bridge within the Fraser River South Arm will provide a 200-m navigation channel with two 61-m safety zones on either side of the navigation channel. This will support existing and future use.

The towers that will support the new clear span bridge will be land-based and will not interfere with navigation. The final design for the bridge will also take into account the lighting and marking requirements of the *NPA* for safe navigation.

In Deas Slough, vertical clearance in the local channel will be approximately 20 m above high water. The existing Deas Slough Bridge and piers will be removed to the mud line and be replaced by a longer, single span. This will support future use and will result in an improvement to marine use compared to existing conditions.

Implementation of the above measures will avoid potential effects on marine use during Project operation.

5.2.4.2 Minimization

Submission of a Notice of Works: The Ministry will submit a Notice of Works form addressing the Section 4 (a through e) requirements of the *NPA* for construction activities (i.e., construction of the new bridge and Tunnel decommissioning) that may interfere with marine use. The effects of the works, as per Section 4d of the Act, will include measures proposed by the Ministry to ensure maintenance of the navigation channel during construction. These mitigation measures will include the establishment of navigation protection zones that will be maintained during marine-based construction activities. Navigation protection zones will be established in consultation with the Marine Users Group to designate areas where navigation can occur safely during construction. These areas will be delineated by navigational aids such as lighting or signage.

Development of a Marine Access Management Plan: A Marine Access Management Plan (MAMP) will be developed (see **Section 12.0 Management Plans**) and will describe the measures to be implemented to minimize potential construction-related access effects on marine use. The MAMP will outline communications protocols to establish and advise of instream construction activities, including periods of vessel restrictions and is anticipated to include:

- An outline of all marine consultation and media-related activities being undertaken by the Project.
- Processes and procedures to inform marine users of any instream activities that may affect access to the navigation channel and other areas frequented by marine users.

- Specific information on construction phasing, work scheduling, and location of instream staging areas required for Project construction and decommissioning activities.
- Issuance and posting of notices regarding construction schedules, as well as updates on access and instream construction activities.
- Establishment of a 24-hour telephone line available to the marine community during new bridge construction and Tunnel decommissioning.
- The MAMP will be reviewed and approved by Transport Canada and will form part of the *NPA* approval for new bridge construction.
- Use BMPs and comply with regulatory requirements, including those related to construction timing windows, notifications, specific mitigation measures.

The Reference Concept for Tunnel decommissioning currently assumes that the four Tunnel elements will be removed over the course of one construction season (i.e., between freshets) and during a window where effects on fish and marine mammals can be minimized (**Section 4.4 Fish and Fish Habitat** and **Section 4.6 Marine Mammals**). The process for removing the Tunnel segments is outlined in **Table 1.1-5**. Tunnel segments will be removed sequentially starting at either the north or south side. During this time, vessel movement will be maintained although may require the establishment of a temporary, one-directional navigation channel with tug-assisted access to allow construction and marine traffic to proceed safely.

Discussion with the Marine Users Group has indicated that a closure of the deep draft navigation channel for four to six hours would not adversely impact shipping scheduling. Communication with the harbour master will minimize scheduling conflicts and ensure that the commercial navigation schedule is maintained as much as possible throughout the construction phase.

Engagement with Marine Users: As discussed in Section 5.2.2.1, the Ministry has continued to engage with commercial and recreational users of the Fraser River South Arm and Deas Slough since March 2014. A marine users group has been established and includes marine stakeholders (e.g., VFPA, Transport Canada, Canadian Coast Guard); marine users potentially affected by Project construction; commercial, recreational, and Aboriginal marine users; Ministry representatives; construction contractors; and representatives of marine communications and traffic services. Ongoing consultation with the marine users group, will support the development and implementation of the MAMP and will help further refine the mitigation measures to be implemented to facilitate construction of the Project while maintaining commercial navigation, navigation for CRA fisheries, and recreational navigation within the Project area.

The marine users group will meet regularly prior to and during Project construction to identify potential access conflicts. The group will also participate in the establishment of processes and procedures to avoid potential conflicts such as construction phasing and scheduling, communications protocol, and frequency of notices. Consultation with the Marine Users Group will continue throughout Project construction.

Implementation of the above measures will minimize potential effects on commercial navigation, navigation for CRA fisheries, and recreational navigation as a result of temporary interruptions of passage through, use of, or access to a section of the Fraser River South Arm and Deas Slough during Project construction.

Timing:

Tunnel decommissioning: Decommissioning of the Tunnel is proposed to occur between July 16 and February 28, the least-risk timing window for the protection of juvenile salmon and eulachon (FREMP 2006), and may occur over two seasons. Adherence to this timing window will allow the navigation channel to be fully open from March 1 to July 15 each year.

Deas Slough Bridge removal: To limit restrictions to navigation within Deas Slough as much as possible, removal of the Deas Slough Bridge is proposed to occur primarily at night. In order for works to proceed safely, this may require temporary full closures of Deas Slough. It is assumed that the majority of Deas Slough use would be daytime and this will have a minimal effect on marine use within Deas Slough.

Aboriginal Group Consultation: Maintaining fishing opportunities for Aboriginal Groups to exercise cultural, economic, and social fishing rights during construction is a key objective of the Marine Access Management Plan that will be developed to support ongoing use of the Fraser River South Arm by all interests throughout the Project construction phase. As discussed in **Section 5.2.2.1** and **Section 10.1.3 Aboriginal Interests Assessment**, the Ministry is continuing to work with Schedule B Aboriginal Groups to facilitate participation in the development and implementation of mitigation measures to avoid, reduce, or otherwise manage potential Project-related effects on Aboriginal Interests, including Aboriginal fisheries activities.

5.2.5 Residual Effects and their Significance

Residual effects on marine use were characterized by qualitatively assessing the direction, magnitude, geographic extent, duration, frequency, and reversibility of the effects. Definitions for the ratings applied to the residual effect are presented in **Table 5.2-5**. These ratings were developed with specific reference to marine use in the LAA and RAA, and reflect the importance

of commercial navigation, CRA fisheries navigation and recreational navigation within the Fraser River South Arm and Deas Slough. Context for the characterization of residual effects, i.e. sensitivity/resilience of marine use in the Fraser River South Arm and Deas Slough to potential Project-related effects, based on existing conditions, has been taken into account in characterizing the residual effects.

Table 5.2-5 Criteria Used to Characterize Residual Effects on Commercial Navigation, Navigation for CRA Fisheries, and Recreational Navigation

| Criteria | Description | Definition of Rating | |
|-----------|---|----------------------|---|
| Direction | Overall nature of the residual effect | Adverse | Measureable negative effect on marine use |
| | | Positive | Measureable positive effect on marine use |
| | | Neutral | No or non-detectable effect on marine use |
| Magnitude | Amount of the effect relative to natural or baseline conditions | Negligible | <ul style="list-style-type: none"> Fraser River South Arm: No restriction Deas Slough: No restriction |
| | | Low | <ul style="list-style-type: none"> Fraser River South Arm: maintenance of two-way navigation channel with tug assisted access Deas Slough: periodic nightly closure |
| | | Moderate | <ul style="list-style-type: none"> Fraser River South Arm: maintenance of one-way navigation channel with tug assisted access Deas Slough: multi-day closure |
| | | High | <ul style="list-style-type: none"> Fraser River South Arm: full closure of navigation channel Deas Slough: multi-week closure |
| Extent | Geographic extent / distribution of the residual effect | Site | Project area |
| | | Local | <ul style="list-style-type: none"> Fraser River South Arm: 2.5 km downstream and 5 km upstream of the Tunnel Deas Slough: 500 m on either side of Deas Slough |
| | | Regional | Fraser River South Arm from approximately three kilometers southwest of the Alex Fraser Bridge to the river mouth |

| Criteria | Description | Definition of Rating | |
|---------------|---|----------------------|--|
| Duration | Length of time over which the residual effect is expected to persist | Negligible | Effect is expected to last less than 1 month |
| | | Short-term | Effect is expected to last less than 6 months |
| | | Moderate | Effect is expected to last between 6 to 18 months |
| | | Severe | Effect is permanent |
| Frequency | Nature of the occurrence of the residual effect (e.g., how often the stressor impacts marine use) | Isolated | Single occurrence or unexpected event |
| | | Rare | Up to twice per week |
| | | Occasional | Two to four occurrences per week |
| | | Continuous | Daily occurrence |
| Reversibility | Potential for the effect to be reversed or naturally return to baseline level after the disturbance has ceased (or following a period of time after the disturbance has ceased) | Reversible | Existing conditions will be restored after effect has ceased |
| | | Irreversible | Existing conditions will not be restored after effect ceases |
| | | Change | Effect may fluctuate between positive and adverse for the duration |
| Likelihood | Likelihood that the residual effect may occur | Low | Likelihood of residual effect is less than 25%. |
| | | Moderate | Likelihood of residual effect is between 25% and 75%. |
| | | High | Likelihood of residual effect is greater than 75%. |

5.2.5.1 Construction

As described in **Section 5.2.3**, the Project has the potential to temporarily affect marine access, and the volume and frequency of marine traffic, during construction activities such as bridge construction, removal of Deas Slough Bridge, and Tunnel decommissioning. With the implementation of mitigation measures discussed in **Section 5.2.4**, it is expected that these effects can substantially be mitigated; however, short-term effects during construction cannot be avoided, and Project construction is anticipated to have the following temporary residual effect:

- Changes in commercial navigation, navigation for CRA fisheries, and recreational navigation in Fraser River South Arm and Deas Slough during marine-based construction activities

A detailed characterization of the above construction-related residual effect is provided below, and a summary of the criteria ratings presented in **Table 5.2-6**.

Context: The Fraser River South Arm supports a variety of marine uses, including international and domestic shipping; commercial, recreational and Aboriginal (CRA) fishing; and recreational boating and moorage. Given the importance of these activities to provincial and federal economies, Aboriginal Groups, many businesses, and the general public, sensitivity of marine use in the Fraser River South Arm to changes or access limitations to the navigation channel can be considered to be relatively high. Mitigation measures identified in **Section 5.2.4**, which include maintaining continued access to the navigation channel during construction, have been proposed, taking this sensitivity into account. Sensitivity of marine use to post-mitigation construction-related effects is, therefore, considered to be low.

Table 5.2-6 Summary of Criteria Ratings for Changes to Commercial Navigation, Navigation for CRA fisheries, and Recreational Navigation

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|-----------|-----------------|--|
| Direction | Adverse | Effect on marine use anticipated due to changes in access to waterways or marine traffic frequency and volume. |
| Magnitude | Low to Moderate | <ul style="list-style-type: none"> • Fraser River South Arm: Maintenance of one or two-way navigation channel with tug assisted access • Deas Slough: periodic nightly closure |
| Extent | Local | <ul style="list-style-type: none"> • Fraser River South Arm: 2.5 km downstream and 5 km upstream of the Tunnel • Deas Slough: 500 m on either side of Deas Slough |

| Criteria | Criteria Rating | Rationale for Criteria Rating |
|---------------|-----------------|---|
| Duration | Short term | Effect will be short-term, temporary, and limited to Project construction activities requiring marine-based vessels or equipment. |
| Frequency | Occasional | Effect is anticipated to occur two to four times per week |
| Reversibility | Reversible | Effect will be reversed following completion of Project construction. |
| Likelihood | High | The likelihood of temporary changes in marine use during Project construction activities requiring marine-based vessels and equipment is anticipated to be greater than 75% |

During construction of the new bridge and decommissioning of the Tunnel, low to moderate adverse effects could be expected within the navigation channel of the Fraser River South Arm. The navigation channel will remain open at all times. As described in **Section 5.2.3 Potential Effects**, partial restriction of the navigation channel may be required during construction of the bridge portion that spans over the central portion of the Fraser River South Arm, and during decommissioning of the Tunnel. This may require a one-way navigation channel. Vessels traveling through the channel during this time will be assisted by tug boats. It is anticipated that a two-way navigation channel will be maintained during construction of the northern and southern most portions of the bridge spans. During this time, vessels would be able to travel in both directions, assisted by tug boats as required. The extent of the effect of Project construction on marine use is considered to be local. Marine-based construction activities will occur primarily within the Project area, and with mitigation, associated effects on marine use are not expected to extend beyond the LAA. Construction of the new bridge and decommissioning of the Tunnel are expected to be moderate in duration. Decommissioning of the Tunnel will be of shorter-term duration, occurring between July and February. Construction of the new bridge is anticipated to involve installation of a new section of the bridge deck one or two times per week, working from the abutments and approaches outward toward the center of the Fraser River South Arm. Decommissioning of the Tunnel is anticipated to involve removal of the four in-river segments of the Tunnel, requiring restrictions to the navigation channel on an intermittent (two to four times per week) basis. Given this, the frequency of potential construction-related effects on marine use is considered to be occasional. Following completion of construction, marine use within and adjacent to the Project area will be restored to baseline conditions, and Project-related effects to marine use are fully reversible.

As described in **Section 5.2.3 Potential Effects**, construction of the south approach to the new bridge and removal of the Deas Slough Bridge has the potential to affect marine activity within/along Deas Slough temporarily. Although full closure of Deas Slough will be required during some activities (such as decommissioning the Deas Slough Bridge and construction the new bridge approach and foundations at this location), such work will be of short duration and will be scheduled for nights whenever possible. Nighttime closures will minimize the effect on marine users within Deas Slough as it is understood that most activity within Deas Slough is daytime recreational use. The extent of the effect is expected to be local. Construction activities within Deas Slough will be limited to Project area, and with the mitigation applied, the effect is not expected to extent past 500 m on either side of Deas Slough. The duration is expected to be short-term and it is expected that nighttime closures would occur occasionally during construction of the new bridge component spanning Deas Slough, and decommissioning of the Deas Slough Bridge. Construction-related effects on marine use within Deas Slough are fully reversible. Removal of the Deas Slough Bridge will result in an increase in air draft from 2.5 metres to 20 metres, which will result in an improvement in navigation conditions within Deas Slough following completion of Project construction.

Potential construction-related residual effects of the Project on marine use are considered to be adverse in direction, low to moderate in magnitude, local in extent, short-term in duration, occasional in frequency, and reversible.

5.2.5.2 Operation

The new bridge has been designed in a manner that avoids the potential for interaction between the Project and marine use in the Fraser River South Arm, and no post-construction Project-related effects are anticipated.

Removal of the Deas Slough Bridge will eliminate structures in the slough that currently infringe on the local navigation channel. With the replacement of the Deas Slough Bridge, current available air draft of approximately 2.5 metres will be increased to approximately 20 metres, and the existing three span crossing will be replaced by a single, longer span structure. These Project-related changes are expected to have a positive effect on marine use in Deas Slough during the operational phase.

5.2.5.3 Proponent's Determination of Significance

Definition of significance: A residual effect on marine use, specifically, access to the Fraser River South Arm and Deas Slough, would be considered significant where Project works require a closure of the entire navigation channel for more than 12 hours, or the deep draft channel for more than 24 hours. This significance threshold relating to marine use is based on the Ministry's understanding of existing marine uses and is informed by consultation with marine users and Aboriginal Groups to-date. Based on such consultation, it is assumed that constraints on access more substantive than those noted above would result in potential economic impacts on commercial marine operators and/or prevent access to CRA fisheries opportunities.

Significance determination: There will be no full closures of the navigation channel during the construction phase and no change in access during the operations phase. The most notable constraints on access during construction will be limited to:

- Occasional closures of the deep draft channel (8-10 hours, up to twice per week) during Tunnel decommissioning.
- The need for occasional (2-4 times per week) tug-assisted transit through the navigation protection zone during Tunnel removal.

Since Project works do not require a closure of the entire navigation channel for more than 12 hours or the deep draft channel for more than 24 hours, Project-related residual effects on marine use are not considered significant.

5.2.5.4 Confidence and Risk

Prediction of confidence was based on the assumption that the anticipated construction activities are reasonably accurate and that the recommended mitigation measures will be implemented. With respect to mitigation measures, the confidence associated with the effectiveness of the mitigation measures is that they have been successfully implemented by the Ministry on other projects in B.C.

Low, moderate, or high confidence reflects the level of uncertainty associated with determinations of likelihood and significance. The level of confidence in the effects prediction for marine use, associated with both the significance determination and the likelihood, is high.

Given the confidence level in the effects prediction and the anticipated moderate residual effects, risk is determined to be low and risk analysis is not required (see methods **Section 3.9 Confidence and Risk**).

5.2.6 Cumulative Effects and their Significance

During construction, no temporal or spatial effects of other Projects are anticipated to overlap with the temporary effects associated with the Project. During operation, no residual effects are anticipated. An assessment of cumulative effects is not required.

5.2.7 Follow-up Strategy

Project-related effects are anticipated to be limited to those associated with marine-based construction activities. During construction, monitoring will include assessment of the implementation and effectiveness of the mitigation applied, including compliance with the Notice of Works and the MAMP. A post-construction follow-up strategy is not proposed.

5.3 Land Use Assessment Highlights:

- The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way.
- Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill.
- The Project is consistent with local and regional land use plans, and aligns with and serves adjacent land uses that have evolved along the Highway 99 corridor. It will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans.
- The Project is not anticipated to affect the planned distribution of regional population and employment growth predicted in Metro Vancouver’s regional growth strategy, overall regional population growth and distribution trends or current trends in industrial land use and development.
- Once the new bridge becomes operational, recreational experience in its vicinity is expected to change due to:
 - Improved connectivity across Deas Island Regional Park resulting from removal of the Tunnel portals.
 - Improvements in local air quality, Deas Island shoreline restoration and revegetation of areas that currently support highway infrastructure.
 - Shading adjacent to the bridge, overhead noise, and changes in local viewscales.
- The Project will not result in changes to existing land use beyond the small amounts of land that are required outside of the existing right-of-way.
- Potential temporary effects on existing land use during construction will be addressed by developing and implementing a Construction Traffic Management Plan.
- No significant Project-related residual effects or cumulative effects on land use are expected.

5.3 Land Use

This section presents the results of the assessment of potential effects of the Project on land use and includes a description of existing conditions, potential Project-related effects and proposed mitigation measures, and an evaluation of residual Project-related and cumulative effects.

5.3.1 Context and Boundaries

This section describes the context for assessing Project-related effects on land use, and defines the spatial, temporal, administrative and technical assessment boundaries. Rationale for selecting the assessment boundaries as defined is also provided.

5.3.1.1 Assessment Context

The Project involves upgrades to an existing transportation corridor. The majority of the Project works will occur within the existing Highway 99 right-of-way (ROW), and is consistent with that existing land use; however, a limited area of private land, outside the Highway 99 ROW, may be required. Project construction may also lead to temporary changes in land and resource use within and adjacent to the Project alignment.

Regional growth strategies support the development of policies for managing anticipated population growth and its distribution within the region, within designated land uses, in coordination with local government planning. These land use planning and development policies are supported by, and to an extent implemented by, regional and provincial transportation policies and initiatives. Therefore, while the Project has been proposed in response to local, regional, and provincial transportation planning objectives and congestion concerns, it may also have the potential to influence regional growth rates and growth distribution.

5.3.1.2 Methodology

The assessment of land use follows the general methodology that is applied to all VCs, as described in **Section 3.0 Assessment Methodology**. Building on this approach, the assessment of land use focuses on two subcomponents: land use and regional growth.

The Ministry's pre-application consultation with local and regional governments between 2012 and 2015 identified concerns related to potential Project-related effects on local/site-specific land use as well as broader regional growth considerations. In response to these concerns, the Ministry identified two subcomponents to support the assessment of the land use VC – **land use** and **regional growth**. Following is a description of these two sub-components and the supporting rationale for their selection.

The **land use subcomponent** considers potential Project-related effects pertaining to local land use within the LAA. These include site specific potential effects as reflected in the indicators presented in **Table 5.3-1**. The indicators are representative of potential site-specific land use effects such as:

- The ability of land use designations to support the proposed Project
- The proposed Project's ability to complement or adversely interact with adjacent land uses

- The extent to which existing land uses could potentially be displaced as a result of the Project
- The extent to which adjacent existing land uses could potentially be disturbed during construction and operations

The **regional growth subcomponent** focuses on considerations related to the extent to which the Project complements measures proposed, by local and regional governments to manage predicted population growth.

The regional growth subcomponent was developed in response to a concern, raised by local and regional governments, that increased capacity on the Highway 99 corridor could result in induced land use effects such as increased pressure for developable land and changes in the way regional growth is accommodated. To address these concerns, this sub-component considers how improvements in access associated with the Project may result in potential changes in land use, within the context of regional growth management considerations.

The regional growth subcomponent is reflected in the indicators presented in **Table 5.3-1**. The indicators are representative of potential regional land use considerations related to improving access along the Highway 99 corridor south of the Fraser including:

- Potential changes to how predicted growth in population and employment will be accommodated within municipalities adjacent to the Highway 99 corridor
- Potential changes in land use adjacent to the Highway 99 corridor including in areas protected by the Urban Containment Boundary and Agricultural Land Reserve.

The rationale for the indicators selected is provided in **Table 5.3-1**. The qualitative thresholds for these indicators are described in the effects characteristics definitions presented in **Table 5.3-2**.

Table 5.3-1 Indicators for Land Use

| Indicator | Rationale for Selection |
|--|---|
| Land Use Subcomponent | |
| Consistency with land use plans and designations | The Project requires small amounts of land, not currently zoned for transportation. The indicator supports the assessment of consistency between existing land uses and those potentially required for the Project. |
| Compatibility with adjacent or proximal land uses | Changes to existing transportation infrastructure have the potential to change the compatibility between land use within the existing right-of-way and adjacent land uses. The indicator supports consideration of the extent to which the Project is aligned with or complementary to adjacent land uses. |
| Spatial area (ha) of change in existing land uses | Describing the spatial area of changes in land use, resulting from the Project, provides an indicator of the extent to which the Project may result in changes to land uses beyond the existing ROW. |
| Disturbance to other land uses from Project-related activities, including disturbance to: <ul style="list-style-type: none"> • Residential, commercial and industrial uses • Recreational use of Deas Island Regional Park | The Project may result in a disturbance to adjacent land uses. The indicator focuses on identifying where Project construction and operation may result in disturbance effects, including noise, visual and access, on specific land uses, even if these land uses are compatible with land use in the Project right-of-way. |
| Regional Growth Subcomponent | |
| Change in regional population growth and distribution | Considering potential changes in the distribution of planned population and employment growth relative to established targets provided in local and regional land use plans, provides a measure for assessing the extent to which the Project complements these plans' objectives for managing predicted growth adjacent to Highway 99 and in the broader region. |
| Change in non-residential land (industrial and commercial) development and distribution | The indicator provides a focus for considering the extent to which the proposed Project may further increase demand for industrial and commercial land in the region. |

5.3.1.3 Assessment Boundaries

Spatial, temporal, administrative, and technical boundaries identified for the assessment of Project-related effects on land use, and the rationale for selecting them are discussed below.

Spatial Boundaries

The local assessment areas (LAA) and regional assessment areas (RAA) for land use are described in **Table 5.3-2**. The spatial boundaries for the both the land use and regional growth subcomponents are shown in **Figure 5.3-1** and **Figure 5.3-2**.

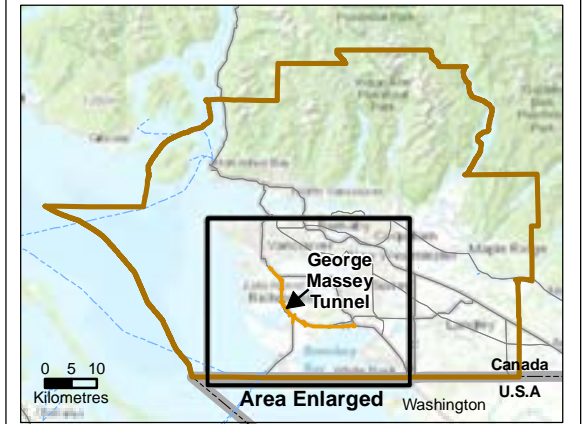

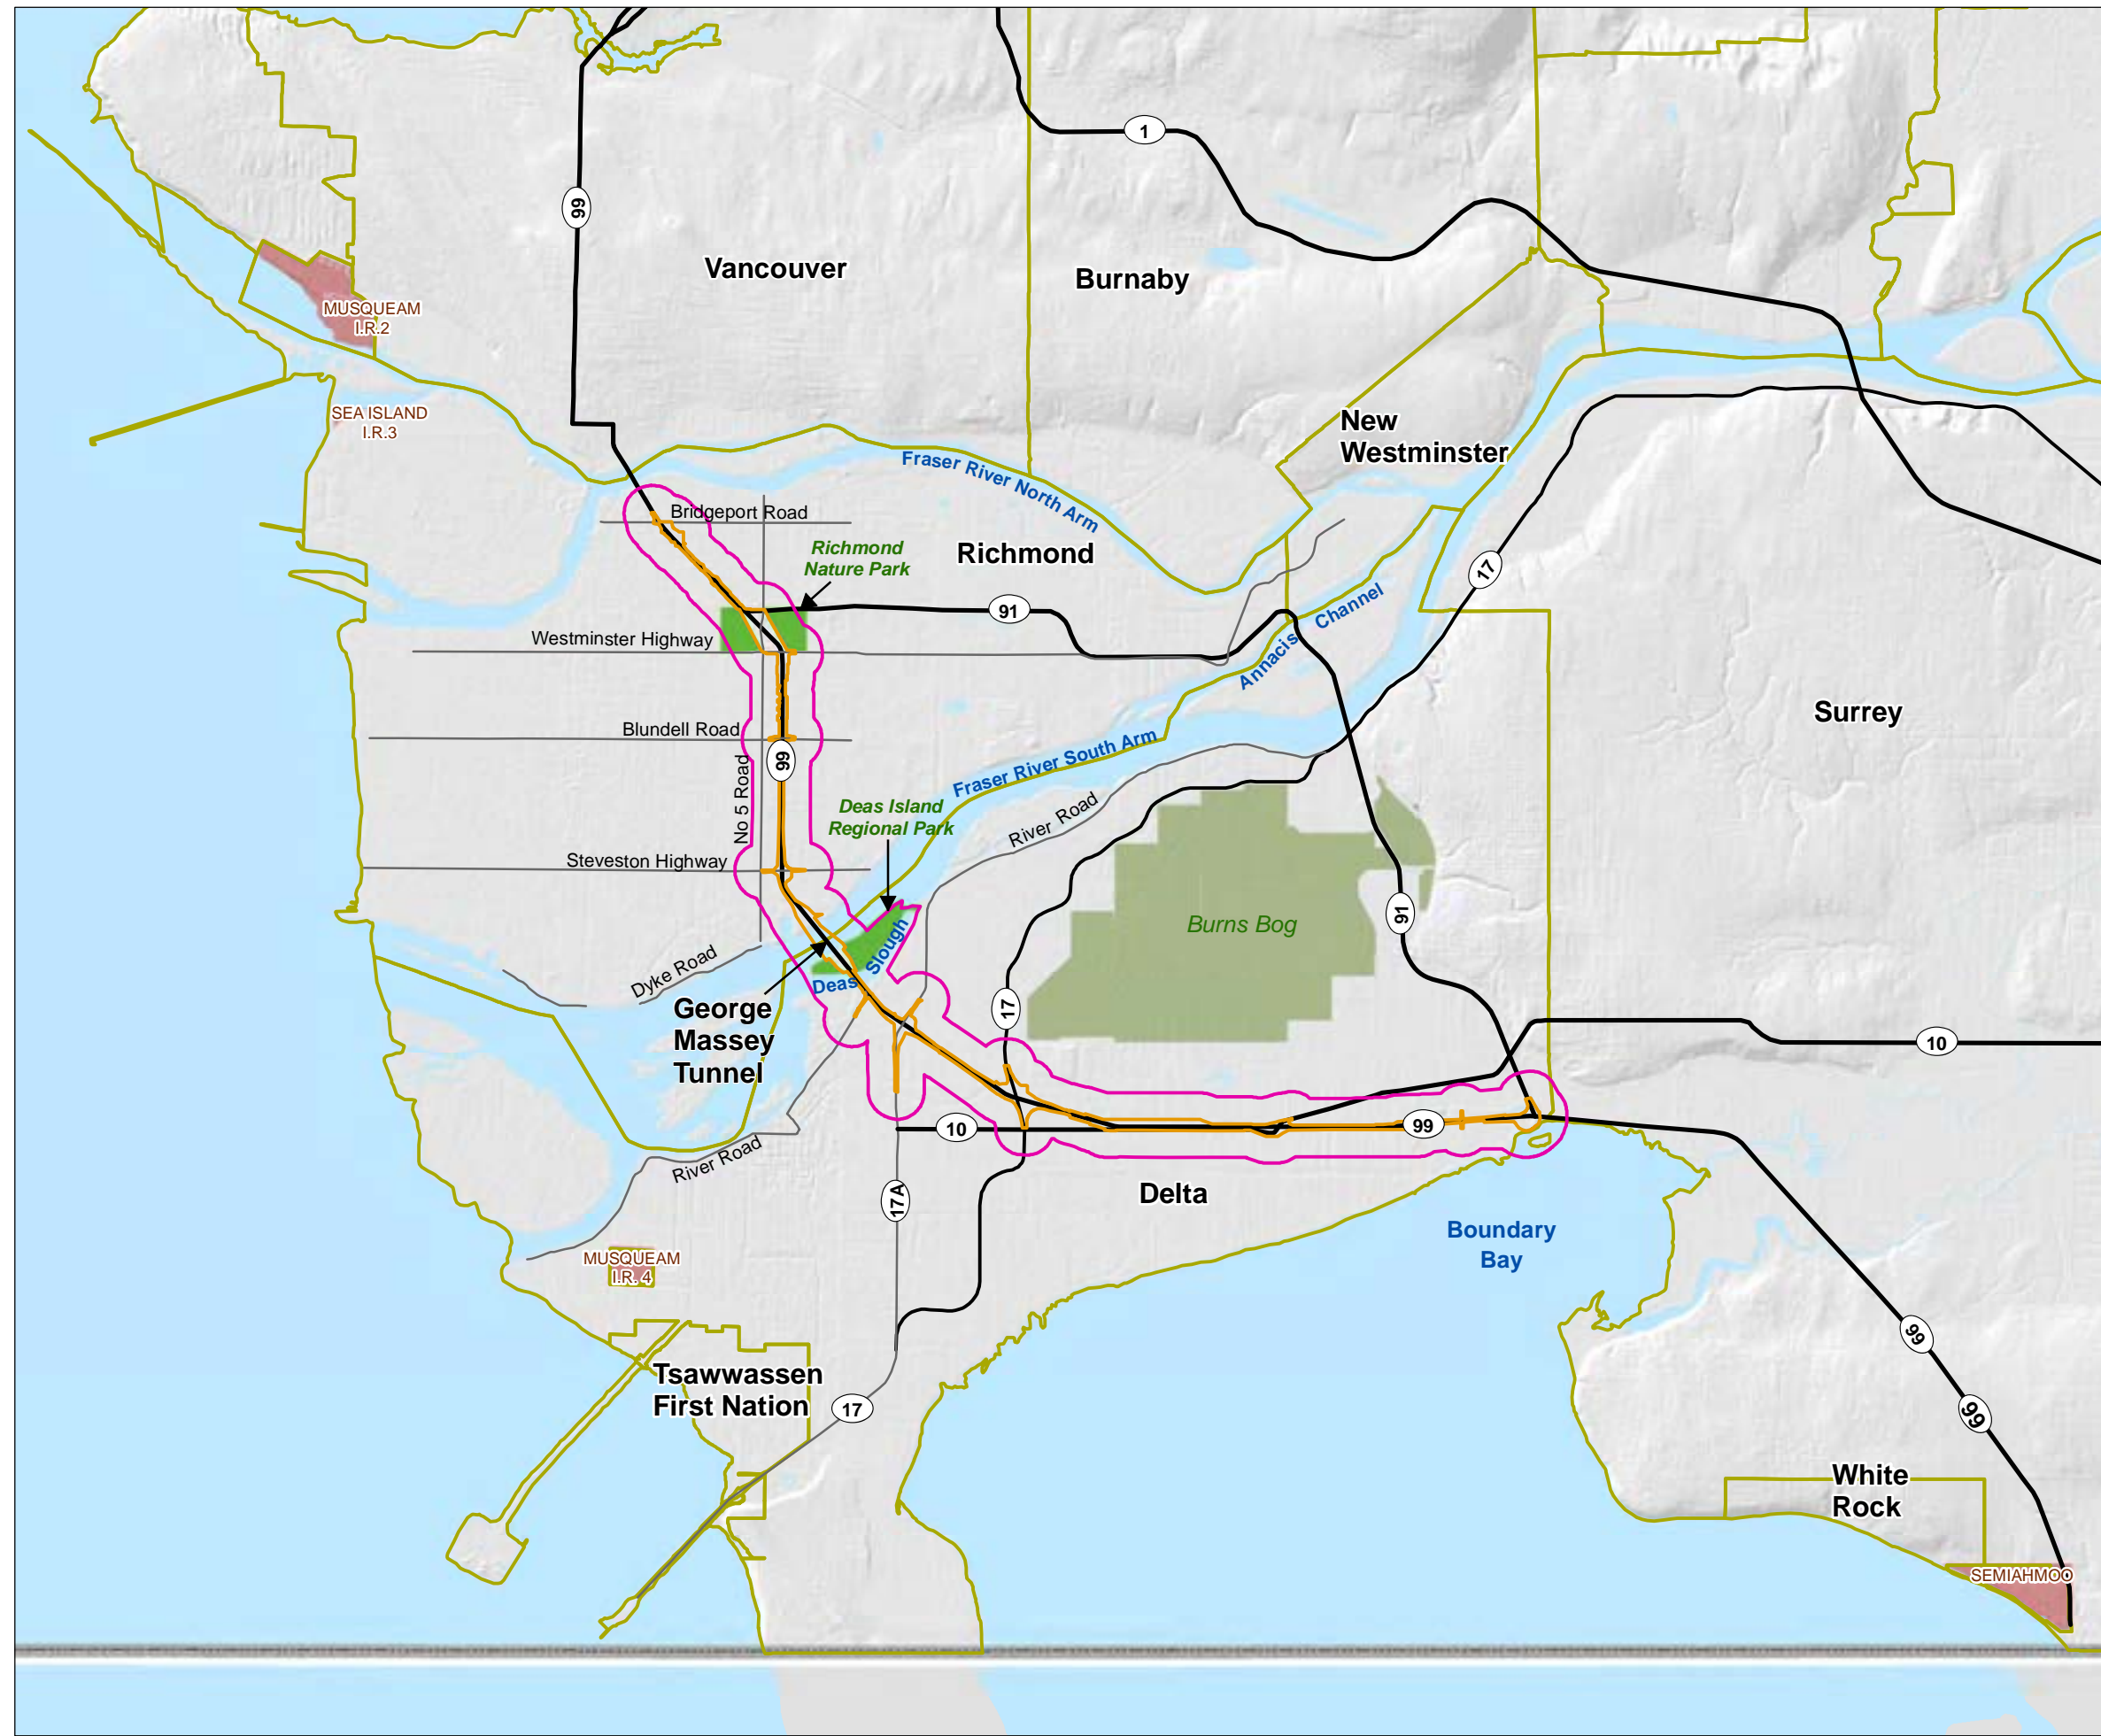

Table 5.3-2 Spatial Boundary for Land Use Assessment

| Spatial Boundary | Description of Assessment Area |
|---------------------------------------|--|
| Land Use Subcomponent | |
| Local assessment area (LAA) | Project alignment plus 500 m on either side of the Project alignment, expanded in the vicinity of the new bridge to include Deas Island and Deas Slough. |
| Regional assessment area (RAA) | The boundary of Metro Vancouver. |
| Regional Growth Subcomponent | |
| Local assessment area (LAA) | The boundaries of City of Richmond (Richmond), Corporation of Delta (Delta), and City of Surrey (Surrey). |
| Regional assessment area (RAA) | The boundary of Metro Vancouver. |

LAAs were established to encompass the area within which the Project could potentially have an effect on either the subcomponents, interact with other values, or both. In determining LAA boundaries, the nature and characteristics of the existing land use plans and regional growth characteristics and the maximum extent of potential effects were considered.

An RAA was established to provide a regional context for the assessment of Project-related effects. The RAA was also used to determine which other potential projects would be relevant in considering project interactions for the cumulative effects assessment. For both subcomponents, the RAA is defined as the geographic area that comprises the Greater Vancouver Regional District, as managed by Metro Vancouver, which is an entity designated by provincial legislation (*Local Government Act*, R.S.B.C. 1996, c. 323) as a regional district. It encompasses the communities included in **Figure 5.3-1** and **Figure 5.3-2**.

Temporal Boundaries

Temporal boundaries for the assessment of Project-related effects on land use were established based on the potential for each phase of the Project to interact with and have an effect on land use. As discussed in **Section 3.1 Issues Scoping and Selection of Valued Components**, the construction and operational phases of the Project include components and activities that could affect land use within the Project alignment; therefore, the following temporal boundaries were defined for land use assessment:

- Existing conditions
- Project construction:
 - Site preparation and pre-construction activities
 - Highway upgrades
 - Construction of the new bridge
 - Decommissioning and removal of existing highway infrastructure replaced by the Project, including underpasses and the Deas Slough Bridge
 - Decommissioning of the Tunnel and removal of four in-river tunnel segments
- Project operation (including maintenance)

Temporal characteristics of the Project phases are discussed in **Section 1.1.4 Project Phases and Schedule**. Specific temporal considerations for the land use assessment are discussed in the context of Project interactions and potential effects in **Section 5.3.3**.

Administrative Boundaries

The LAA for the regional growth subcomponent and the RAAs for subcomponents are defined by the administrative boundaries for local and regional governments (**Figure 5.3-1** and **Figure 5.3-2**). These boundaries support the assessment of compatibility with local government land use designations, and provide context for these and other non-local government designations pertaining to the Highway 99 corridor and for regional growth predictions.

Technical Boundaries

No constraints, such as accessibility or gaps in data that could limit the ability to predict the effects of the Project on land use, have been identified; therefore, no technical boundaries were defined.

5.3.2 Existing Conditions

This section provides an overview of the methodology for collecting baseline data, and describes the existing conditions of land use within the assessment areas. An overview of the regulatory context as relevant to land use is also provided. Information on existing conditions, presented in the following sections, supports the sub-components, land use and regional growth.

Section 10.0 Aboriginal Consultation assesses potential effects on Aboriginal Interests, defined as asserted or determined Aboriginal rights, including title, and treaty rights, including those that relate to potential changes in land use. While a detailed assessment of potential effects on the exercise of Aboriginal Interests, including those with a land use aspect, are provided in **Section 10.0**, an overview of such information is provided below to acknowledge Aboriginal land use considerations in the context of the assessment.

Based on information presented in **Section 10.0 Aboriginal Consultation**, the Project area has and continues to support land uses related to the continued exercise of Aboriginal Interests. Traditional use and traditional knowledge information that was gathered to support the assessment of Aboriginal Interests, described in **Section 10.0 Aboriginal Consultation**, includes activities such as fishing, hunting/trapping, and gathering, as well as related interests, such as language and culture (e.g., as represented by named places), cultural sites (e.g., habitation sites, sacred or spiritual areas, transportation routes), and cultural landscapes.

5.3.2.1 Baseline Data Collection

As part of early Project planning in 2012 and 2013, the Ministry reviewed Metro Vancouver's then newly updated regional growth strategy and municipal land use plans. To support ongoing Project planning, and subsequently, this assessment, more detailed technical studies on land use commenced in 2014. Building on available information, these studies were designed to address known data gaps. Specific desktop studies conducted for the land use assessment are as follows:

- Review of land ownership and Crown land tenures in the provincial and municipal databases.
- Review of regional and community planning documents and bylaws including but not limited to:
 - Metro Vancouver's Regional Growth Strategy (RGS) (2011 and 2015)

- Official Community Plans of Richmond (2016), Delta (2014), and Surrey (2013)
- TransLink's Regional Transportation Strategy Strategic Framework (2013)
- TransLink's 2014 Base Plan and Outlook (2014)
- Port Metro Vancouver Land Use Plan (2014)
- Review of information gathered through public and stakeholder consultation processes (**Section 10.0 Aboriginal Consultation** and **Section 11.0 Public Consultation**).
- Review of satellite images and aerial photographs to determine existing land uses.

These desktop studies provided appropriate information at a sufficient level of detail needed to carry out the assessment.

Preliminary consultation identified concerns from Aboriginal Groups and Metro Vancouver regarding recreational use of Deas Island Regional Park and the Millennium Trail, and the potential long term effects on land use related to potential changes in regional growth as a result of the Project (note that agriculture is considered in **Section 5.4 Agricultural Use**). Accordingly, the LAA for the land use subcomponent has been expanded to include the entirety of Deas Island Regional Park, and information on potential effects to recreation in Deas Island Regional Park and vicinity have been considered in further detail. A regional growth subcomponent has also been introduced to this section, to assess potential effects of improved access in relation to regional growth and distribution of growth within the region

5.3.2.2 Regulatory Context

Land use along the Project alignment is regulated through federal and provincial legislation, or municipal bylaws, primarily through the following:

- *Canada Marine Act*, S.C. 1998, c. 10, which establishes federal navigation jurisdiction by Port of Vancouver in the Fraser River.
- *Navigation Protection Act*, (R.S.C., 1985, c.N-22) establishes authorization for works in navigable waters, including the Fraser River.
- *Agricultural Land Commission Act*, S.B.C. 2002, c. 36, which establishes the provincial Agricultural Land Reserve (ALR) and permitted uses within them.
- *Land Act*, R.S.B.C. 1996, c. 245, which establishes tenure policies for provincial Crown land.

- *Wildlife Act*, R.S.B.C. 1996, c. 488, which establishes Wildlife Management Areas (WMAs) for conservation purposes.
- *Community Charter*, S.B.C. 2003, c. 26, which establishes the legal framework for core municipal powers.
- *Local Government Act*, R.S.B.C. 1996, c. 323, which establishes the legal framework for regional districts, the authority for regional growth strategies and regional parks, and local government planning and zoning bylaws.

5.3.2.3 Land Ownership

This section describes land ownership, applicable land use plans and regulations, and current uses and tenures, as well as projects and activities that are occurring within and near the Project alignment.

The Project is sited largely on provincial Crown land within Richmond and Delta, and straddling the Fraser River South Arm, and the alignment follows the existing Highway 99 alignment (**Figure 5.3-3**).

Richmond, Delta, and Surrey

Land within the communities most likely to experience direct Project effects (i.e., Richmond, Delta, and Surrey) is owned by federal, provincial, or local governments; First Nations; or is privately held. The federal government owns the submerged land in the Fraser River North and Middle Arms, the portion of submerged land under the Fraser River west of Tilbury Island and several parcels of foreshore and upland areas in Richmond and Delta. Submerged land in the Fraser River South Arm east of Tilbury Island is owned by the Province (including the submerged land in the Project alignment), which also manages tenures for uses within this area. Vancouver Fraser Port Authority (VFPA, doing business as Port of Vancouver), has jurisdiction over navigation in the Fraser River and owns several upland properties (VFPA 2014).

Provincial land holdings in these cities include the BC Ferries fleet maintenance facility (Deas Pacific Marine) in south Richmond, portions of the South Arm Marshes Wildlife Management Area (WMA), and smaller parcels in upland areas of Delta. Ownership of the Burns Bog Ecological Conservancy Area is shared between the Province and a partnership between Metro Vancouver and Delta. The City of Vancouver owns the Vancouver Landfill, situated between Highway 99 and the southwest corner of Burns Bog. Delta owns the land

base for the Boundary Bay Airport, as well as several parks and recreational corridors. Richmond and Delta own the land base for their respective arterial and local roads, community centres, local parks and public works facilities. The remainder of land, which includes a Canadian National (CN) rail corridor in Richmond and a Burlington Northern Santa Fe rail corridor in Delta, is privately owned.

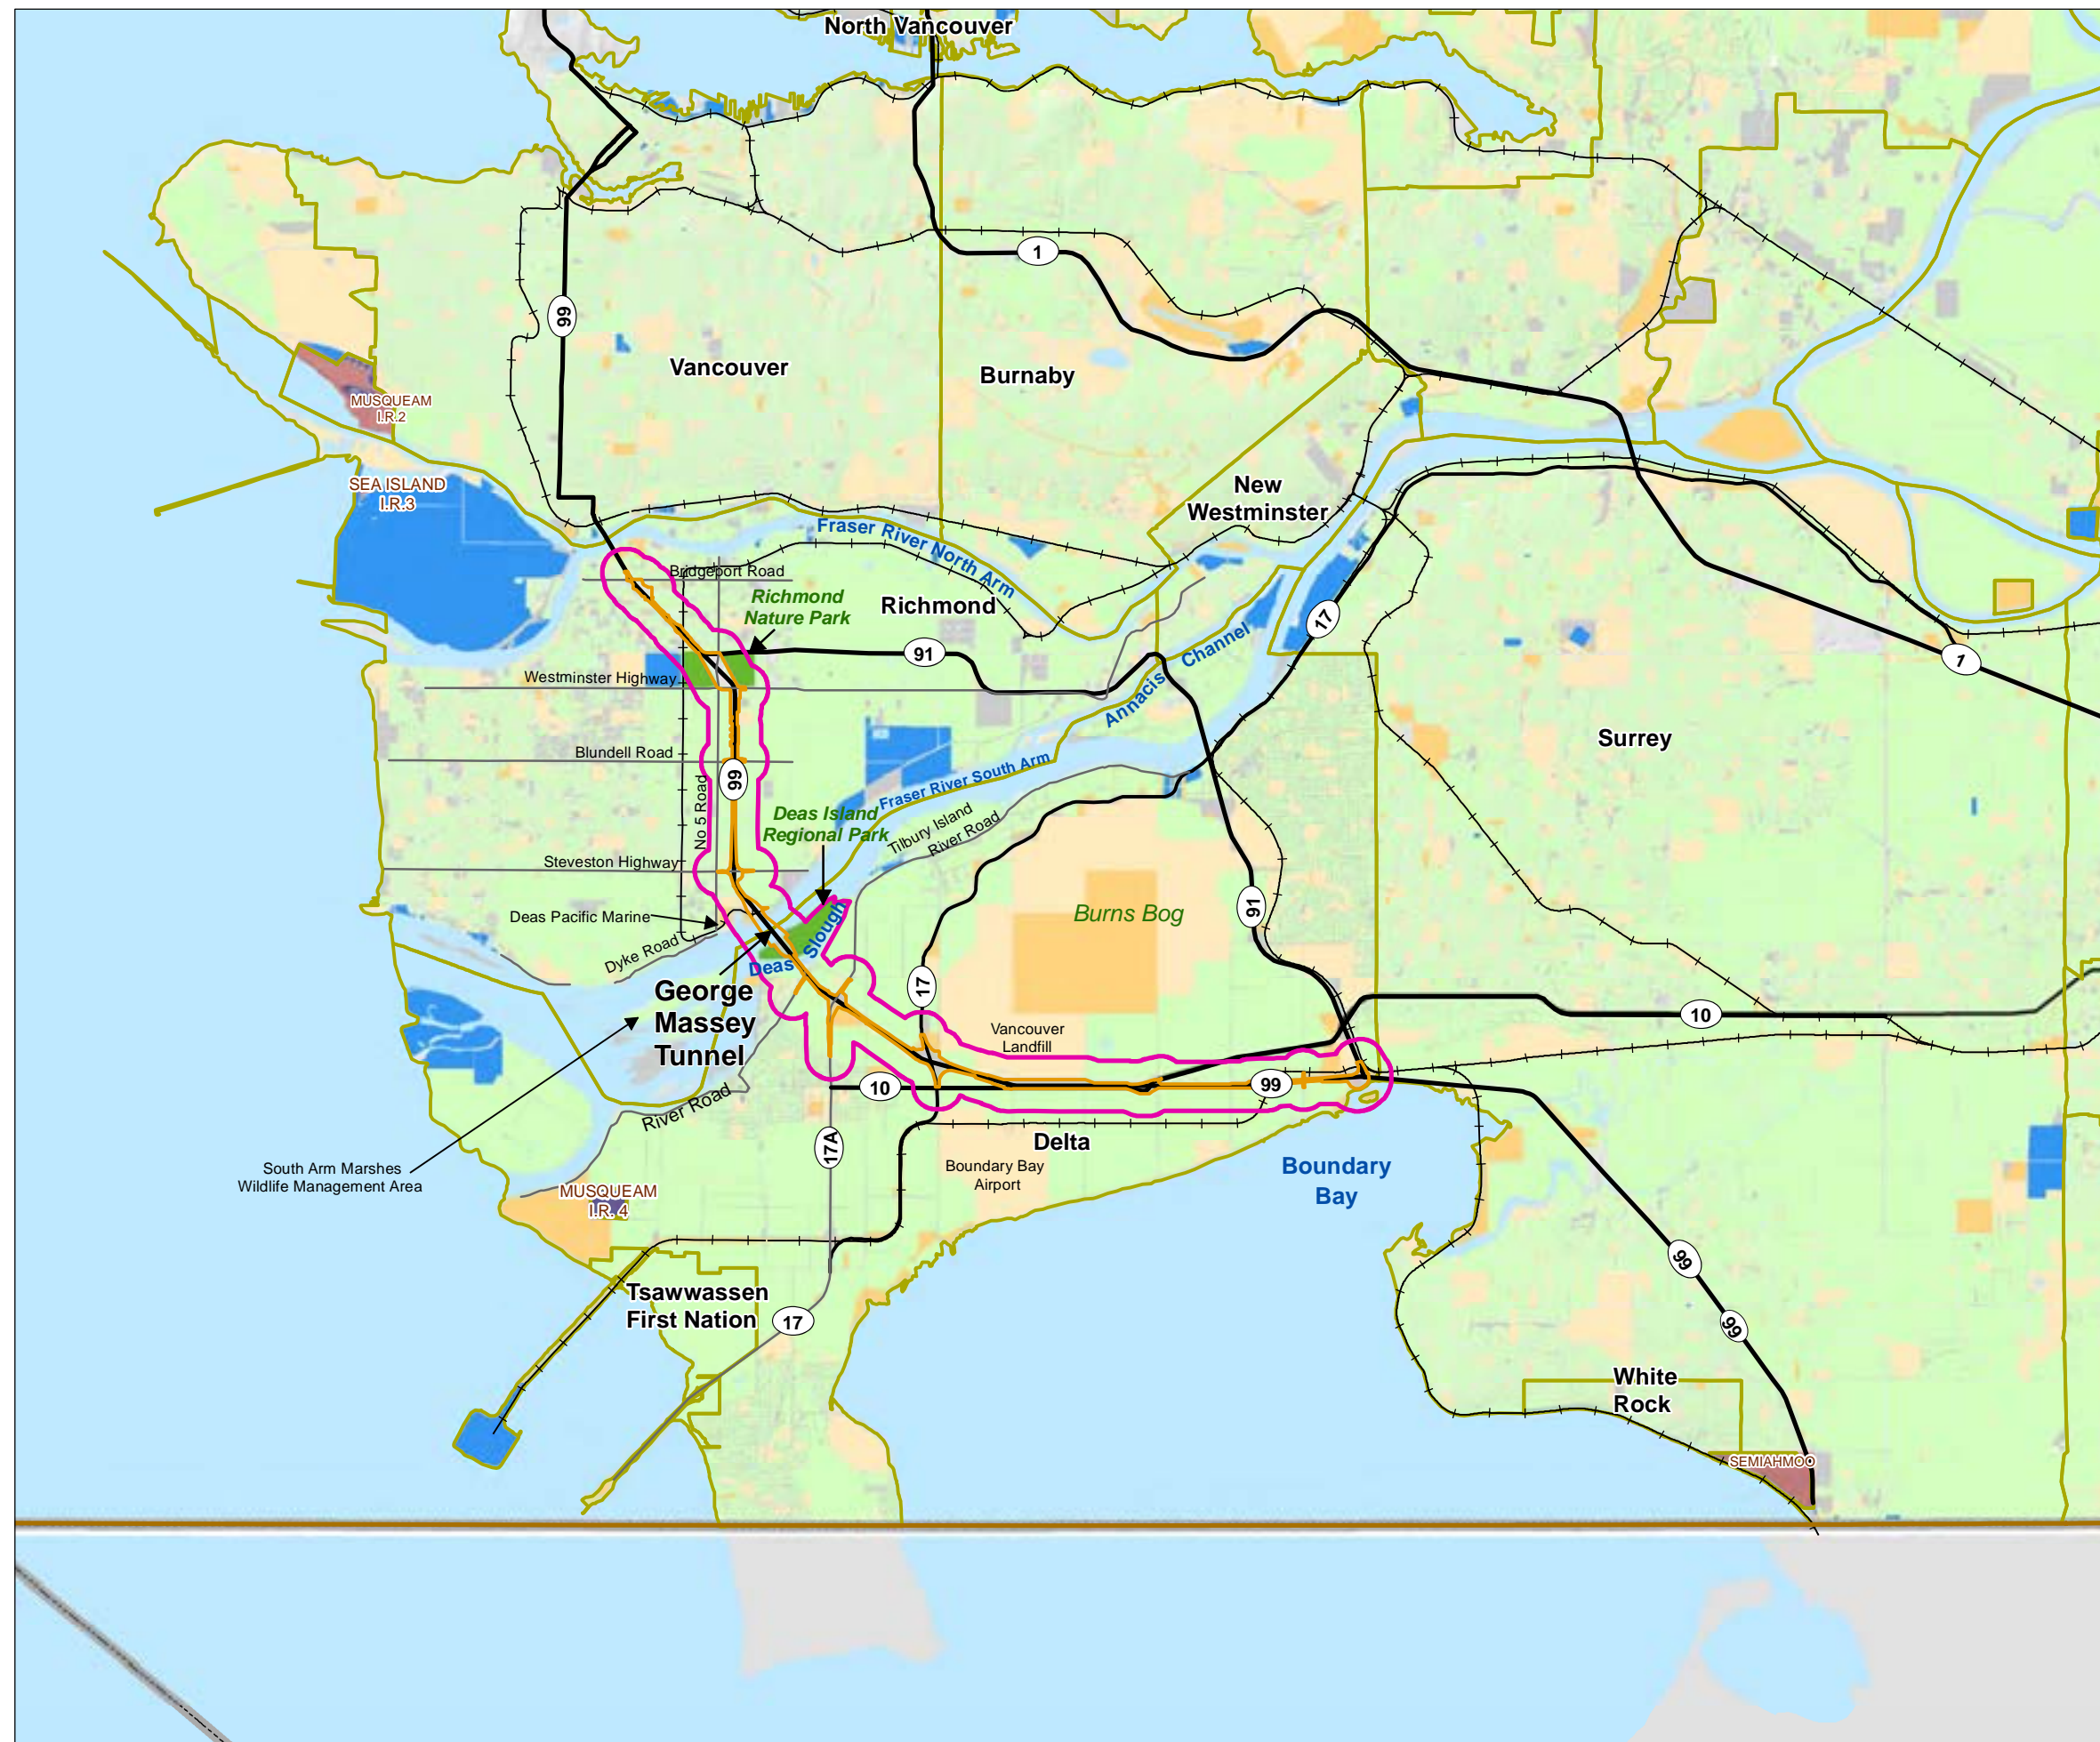

Tsawwassen First Nation Lands, as defined by the *Tsawwassen First Nation Final Agreement* (2009), are located within the RAA, approximately six kilometres southwest of the Project alignment, adjacent to Roberts Bank. Musqueam Indian Reserve No. 4 is located within the RAA, approximately five kilometres northwest of the Project alignment (**Figure 5.3-3**). Information on First Nation Treaty lands and Indian Reserves is provided in **Section 10 Aboriginal Consultation**.

Land Use Subcomponent Local Assessment Area

In the LAA, the majority of land adjacent to the Project is privately held. Outside of the Highway 99 ROW (**Figure 5.3-3**), the Province owns some upland parcels and submerged lands adjacent to the Project alignment. Metro Vancouver owns Deas Island Regional Park, which is situated on both sides of the south approach to the Tunnel. Richmond owns several parcels, in addition to the Richmond Nature Park. Delta owns several parcels adjacent to the ROW. The northeast corner of the federally owned (Department of National Defense), approximately 60 ha, parcel to the west of the Richmond Nature Park is within the LAA. The Vancouver Landfill, partially within the LAA, is owned by the City of Vancouver, which operates it under agreement with Delta and Metro Vancouver. Lands to the south of the Landfill within the LAA are municipally owned.

Project Alignment

The majority of the proposed Project alignment is provincial Crown land, including submerged land in the Fraser River. The support structures for the new bridge, on Deas Island, will be within the Highway 99 ROW (i.e., on Crown land) and not in Deas Island Regional Park. The Project will improve connectivity across the Park through removal of the Tunnel portals, although the ROW will continue to bisect the Park. In Richmond, just south of Rice Mill Road, the Highway 99 ROW crosses the CN rail line, which is private land. In Delta, the alignment also crosses privately held rail land.

5.3.2.4 Land Use Planning

This section describes the planning context for the Project, noting policies that pertain to the Project. Land use designations associated with relevant regional and local plans are described.

Overview

Regional land use planning is undertaken by Metro Vancouver, and regional transportation planning by TransLink, with coordination shared between the agencies. The regional priorities, goals, and policies of these two organizations are specified in strategic plans: *Metro Vancouver 2040 Shaping Our Future* (Metro Vancouver 2015) and *Regional Transportation Strategy Strategic Framework* (TransLink 2013). Within these frameworks, local governments prepare Official Community Plans (OCPs) that specify local goals and policies and include regional context statements to demonstrate how the municipality will comply with Metro Vancouver's RGS.

Regional and local land use planning processes recognize the authority of senior levels of government by incorporating federal and provincial land use designations, such as National Wildlife Areas, and zoning, such as the provincial Agricultural Land Reserve (ALR), into their plans. VFPA is a federal entity that has land holdings and authority to develop a land use plan for its holdings (Port Metro Vancouver 2014). Provincial transportation improvements are also planned separately in consideration of the regional context.

Federal and Provincial Lands

VFPA manages designated federal lands at Fraser Wharves, located in Richmond to the northeast of the new bridge, as a port terminal. The westernmost portion of this area, situated along the Fraser River South Arm, is partially within the Land Use Subcomponent LAA (VFPA 2014). The port terminal is designated for deep-sea and marine terminals, which handle a variety of commodities. VFPA maintains navigational jurisdiction in the Fraser River South Arm in the vicinity of the new bridge. However, the submerged lands are under provincial jurisdiction and not managed by VFPA.

Indian Reserves (I.R.) are designated as federal land under the *Indian Act, R.S.C., 1985, c. 1-5*. As shown on **Figure 5.3-3**, three Indian Reserves occur within the boundaries of Richmond, Delta, and Surrey: Sea Island I.R. 3, Musqueam I.R. 4, and Semiahmoo I.R. Information on First Nation Treaty lands and Indian Reserves is provided in **Section 10 Aboriginal Consultation**.

The ALR is a provincial designation in which agriculture is recognized as the priority use. Farming is encouraged and non-agricultural uses are controlled within the ALR (Agricultural Land Commission 2002). The ALR within Richmond, Delta, and Surrey is shown in **Figure 5.3-4**. Local and regional governments, as well as provincial agencies, are expected to plan in accordance with the provincial policy of preserving agricultural land. An application must be made to the Agricultural Land Commission for exclusion of land from the ALR and permission for non-farm uses. Further information on the ALR and agricultural use is presented in **Section 6.4 Agricultural Use**.

Treaty and First Nations Lands

As part of Tsawwassen First Nation's (TFN) *Final Agreement*, a TFN Land Use Plan (AECOM, 2009) was prepared to support TFN's mandate to manage the development of their treaty lands. A detailed land use planning process started in 2007, and included research, analysis and consultation. The resulting plan identified industrial, commercial, agricultural, residential and other land uses, and was approved by TFN government in 2009.

The existing or proposed land uses on TFN Lands include the TFN industrial (135 ha) area and the mixed use/commercial (71 ha) area. To support the Plan, the TFN *Land Use Planning and Development Act* was passed and a *Zoning Regulation* was enacted. The Industrial Lands and Commercial Lands are within a designated Development Permit area under the TFN *Development Permit Area Regulation*. TFN also adopted an Industrial Lands Master Plan (Parsons Brinckerhoff 2009), that evaluated a range of possible industrial activities for the Industrial Lands.

In addition to Tsawwassen First Nation, other Aboriginal Groups listed in Schedule B of the Section 11 Order have land use plans or objectives for reserve lands and lands outside reserves. Information on land use planning and objectives has been described in **Section 10.1.1 Background Information** and **Section 10.1.3 Aboriginal Interests Assessment**, where this information was provided by Schedule B Aboriginal Groups or otherwise available from public sources.

Federal, Provincial, Regional, and Municipal Parks and Protected Areas

Federally protected National Wildlife Areas and Migratory Bird Sanctuaries within Richmond, Delta and Surrey (**Figure 5.3-4**) are:

- Alaksen National Wildlife Area, established under the authority of the *Canada Wildlife Act, R.S.C. 1985, c. W-9*, managed for wildlife conservation, research, and interpretation (Environment Canada 2013). The federal government owns this land and no other uses, other than those previously stated, are permitted.
- George C. Reifel Migratory Bird Sanctuary, which overlaps the Alaksen National Wildlife Area, is managed under the authority of the *Migratory Birds Convention Act (MBCA), S.C. 1994, c.22*, for the protection and conservation of migratory birds (Environment Canada 2014). Public access is not restricted, although standard prohibitions under the *MBCA* apply. The Canadian Wildlife Service and the Province of British Columbia own this land.

Provincial WMAs are the primary designation tool for conservation lands under Section 4 of the *Wildlife Act*. WMAs are created for the purposes of managing wildlife habitat, although other compatible land uses may also be accommodated (Ministry of Forests, Lands and Natural Resource Operations). WMAs within or offshore of the cities of Richmond, Delta, and Surrey (**Figure 5.3-4**) are:

- Boundary Bay Wildlife Management Area
- Serpentine Wildlife Management Area
- South Arm Marshes Wildlife Management Area
- Roberts Bank Wildlife Management Area
- Sturgeon Bank Wildlife Management Area

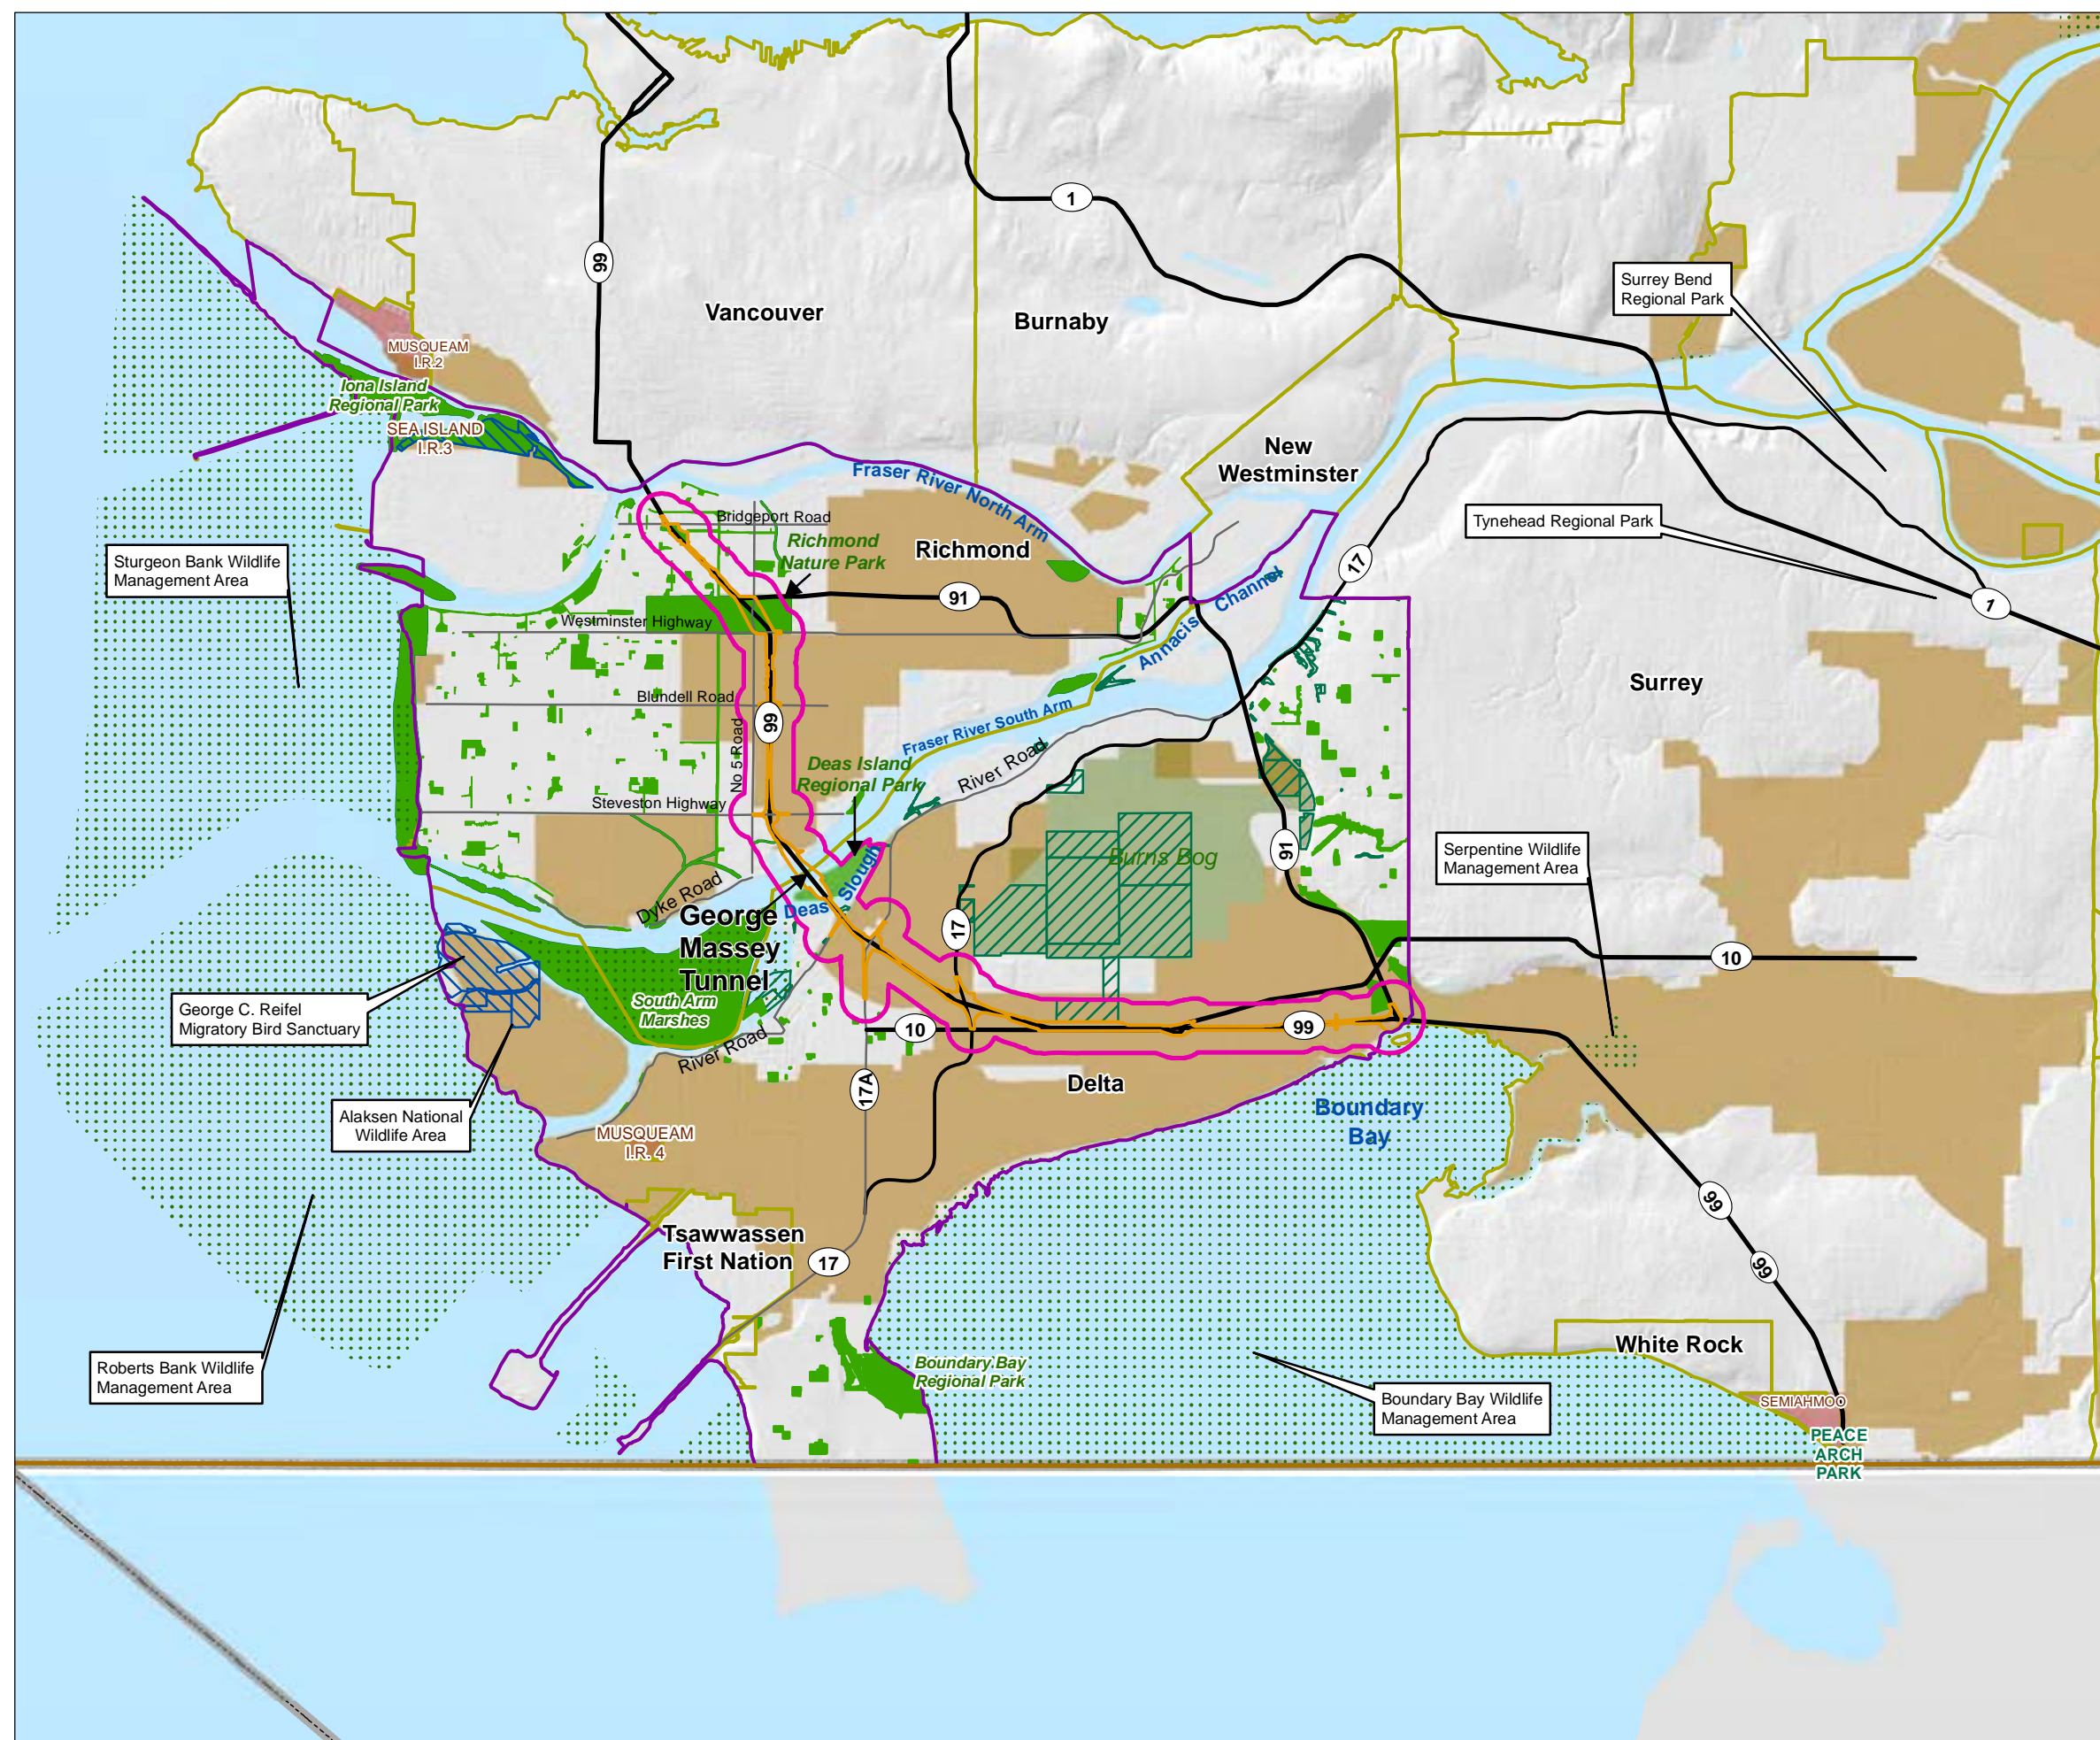

Metro Vancouver manages a system of regional parks, regional park reserves, ecological conservancy areas, and regional greenways. The system protects the region's important natural areas and ecosystems and allows Metro Vancouver's regional population to connect with, enjoy, be active within and learn about the region's environment (Metro Vancouver 2015). Metro Vancouver has designated the following parks or protected areas within Richmond, Delta, and Surrey (**Figure 5.3-4**):

- Deas Island Regional Park
- Iona Beach Regional Park

- Boundary Bay Regional Park
- Surrey Bend Regional Park
- Tynehead Regional Park
- Burns Bog Ecological Conservancy Area
- Delta-South Surrey Regional Greenway

Richmond, Delta, and Surrey have designated Environmentally Sensitive Areas and nature parks in their OCPs (**Section 5.3.2.3**).

Path: O:\1217-299\295\077\03\mxd\LandUse\EIA\Fig_5-3-4_285_077_03_Agr-Parks_16526_FINAL.mxd

Plans and Policies Relevant to the Project

A summary of land use planning at the federal, provincial, regional and local contexts relevant to the Project is provided in **Table 5.3-3**.

Table 5.3-3 Land Use Planning Context at Federal, Provincial, Regional and Local Levels

| Jurisdiction | Responsible Agency or Municipality | Land Use Planning Context |
|--------------|---|--|
| Federal | Vancouver Fraser Port Authority | <p>VFPA's updated <i>Land Use Plan</i> (2014) articulates policies on land use and development and identifies the types of uses that are appropriate on land and water for the federal lands it manages. Policy directions relevant to the proposed Project include:</p> <ul style="list-style-type: none"> • Intensifying use and development of certain Port of Vancouver lands within the existing land base. • Considering the impacts that intensified use may have on adjacent communities, transportation networks, and the environment. • The management of new port development to create synergies and efficiencies between adjacent activities and uses. |
| Provincial | Ministry of Transportation and Infrastructure | <p>The Province has planned for improvements along Highway 99 and the George Massey Tunnel since 1991 (Ward Consulting Group 1991, Reid Crowther and Partners Ltd. and Ward Consulting Group 1995, B.C. MOTI 2006b). The <i>Gateway Program Definition Report</i> (B.C. MOTI 2006b) identified the Tunnel as a potential longer-term priority to meet transportation goals. The Project also is consistent with objectives of the <i>Pacific Gateway Transportation Strategy 2012 to 2020</i> (Government of B.C. 2011) to increase major road capacity and upgrade transportation trade corridors, and with the provincial <i>B.C. on the Move</i> transportation strategy (Government of B.C. 2015) which confirms the Project as a priority to improve highway safety, capacity, and reliability.</p> |

| Jurisdiction | Responsible Agency or Municipality | Land Use Planning Context |
|--------------|------------------------------------|---|
| Regional | Metro Vancouver | <p>Metro Vancouver’s RGS (Metro Vancouver 2015) sets out goals, strategies, and policies to guide the future growth of the region and provides the land use framework for transportation, economic, housing, utility, environmental, and climate change planning. It presents a vision for how the region will accommodate the forecast one million people and over 500,000 jobs expected in the next 25 years.</p> <p>In alignment with the RGS, municipalities prepare and adopt Regional Context Statements (RCS), which must be accepted by the Greater Vancouver Regional District (GVRD) Board. RCSs describe how local aspirations, as expressed in the OCP, support and align with Metro Vancouver’s 2040 goals and policies.</p> <p>The RGS acknowledges TransLink’s mandate for the regional transportation system and communicates to TransLink its objectives to implement strategic transportation plans that support focused growth in urban centres, frequent transit development areas, and other appropriate areas in the frequent transit network (Metro Vancouver 2015). The RGS also requests that TransLink and the province seek, as appropriate and in collaboration with municipalities, to minimize impacts on the environment and public health, from within-and-through vehicle movements for passengers, goods, and services, which affect the region and areas within the lower Fraser Valley airshed.</p> |
| Regional | TransLink | <p>The strategic framework of TransLink’s <i>Regional Transportation Strategy</i> (RTS)(TransLink 2013) identifies a goal to work with the Province to ensure the Project is integrated with the regional network in a way that is consistent with the RGS (Metro Vancouver 2015). The RTS guided the development of TransLink’s <i>2014 Base Plan and Outlook</i> (2013). While this plan does not specifically refer to the Tunnel or its replacement, the plan identifies a goal to strategically maintain and grow the existing transportation system, including the major road network, with partners.</p> <p>The Mayors’ Council on Regional Transportation presents a transportation vision for Metro Vancouver that identifies priorities for roads, rail transit, bus and SeaBus service, and cycling and walking (2015). A primary objective of the vision is to support the region’s land use vision in the RGS by delivering transportation initiatives. It recognizes the importance of a compact urban area that places affordable housing, industrial land, jobs, and major destinations in the right locations such that walking, cycling, and transit are convenient transportation choices and goods movement trips are efficient.</p> |

|--------------|------------------------------------|--|
| Local | Richmond | <p>Richmond’s OCP (2012) notes the existing Highway 99 corridor and identifies a proposed interchange at Steveston Highway, which has been included as a component of the Project. Relevant area and sub-area plans are discussed below:</p> <ul style="list-style-type: none"> • Shellmont Area Plan: A future neighbourhood centre is planned to the west of the Steveston Highway interchange, which is detailed in the Ironwood sub-area plan within the Shellmont area plan. The Ironwood sub-area plan provides development permit guidelines to support a special character within an area around No. 5 Road and Steveston Highway (City of Richmond 2012). One objective of that sub-area plan is to provide measures to manage the high traffic volumes and proximity to Highway 99. • East Richmond Area Plan: The McLennan sub-area plan, within the East Richmond area plan, encompasses the area from Highway 99 west to No. 4 Road, and from Francis Road to Westminster Highway. It focuses on policies for urban/agriculture interfaces. • East Cambie Area Plan: includes an objective to improve transportation access to facilities and services while minimizing the social and environmental impacts of traffic as well as a policy to accommodate smooth traffic flows on arterial streets by improving arterial capacities. • West Cambie Area Plan: This plan contains an objective to provide a circulation system for West Cambie area that allows for vehicle connectivity within and beyond the area • City Centre Area Plan: Land use adjacent to the Project alignment within this sub-area plan is primarily designated as industrial and commercial mixed-use. This sub-area plan includes a policy to ensure industrial land is well served by highway, airport, port, and transit access. |

| Local | Delta | Delta’s OCP (2014) has an objective of reducing traffic congestion and mitigating its effects, working with provincial and federal governments and agencies to secure improvements to transportation systems and maximize the capacity of existing corridors, wherever possible, before building new corridors to accommodate increasing traffic demand. |
| | Surrey | Surrey’s OCP (2014) has objectives to develop efficient and adaptable infrastructure systems and provide a comprehensive transportation network that offers reliable, convenient, and sustainable transportation choices. The OCP defines several relevant policies under this objective which include efficiently managing, maintaining, and improving a transportation system for all modes of transportation, reducing congestion, and coordinating with strategic operational plans of the Ministry. |

Metro Vancouver Regional Growth Strategy

Metro Vancouver’s regional growth strategy identifies several regional land use designations. The designations that apply within Surrey, Delta, and Richmond (i.e., those communities with the potential to be directly affected by the Project) are listed and described in **Table 5.3-4** and shown in **Figure 5.3-5**.

Table 5.3-4 Metro Vancouver Regional Growth Strategy land use designations within the land use subcomponent LAA

| Land Use Designation | Description |
|-----------------------------|---|
| Agricultural | Includes majority of land use adjacent to the Project alignment in Richmond, Delta, and Surrey. |
| Conservation and Recreation | Includes Deas Island Regional Park, the South Arm islands, Burns Bog Ecological Conservancy Area, Richmond Nature Park, the foreshore of Lulu Island and the Strait of Georgia, the north shore of Sea Island, Watershed Park, Tynehead Regional Park, Sunnyside Acres Urban Forest, Crescent Park, Surrey Bend Regional Park, and several other smaller parcels of land scattered throughout Delta, Richmond, and Surrey. |
| General Urban | <p>Includes Ladner, the Tsawwassen lands south of Deltaport Way, North Delta, Tsawwassen and portions of Richmond (neighbourhoods or town centres including Blundell, Bridgeport, Broadmoor, East Cambie, West Cambie, City Centre, Seafair, Shellmont, Steveston, and Thompson). Lands surrounding the Surrey Metro Centre, Guildford, Fleetwood, Newton, Cloverdale and Semiahmoo urban centers are also designated as general urban and future development outside of these areas is constrained by an Urban Containment Boundary. A small portion to the south of the Highway 99 corridor in Ladner is designated as general urban, and borders the Urban Containment Boundary.</p> <p>Urban Centres within the Project alignment (i.e., Metropolitan Cores, Regional City Centres, and Municipal Town Centres) include Richmond Centre (a Regional City Centre), Ladner, Newton, Guilford, Fleetwood, Newton, Cloverdale, and Semiahmoo (Municipal Town Centres), and Surrey Metro Centre, which has its own urban centre designation.</p> |
