The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.

Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.

Effects

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

Mitigation

Minimize effects through Project design.

Implement recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.

Development of an Air Quality and Dust Control Management Plan for inclusion of the Construction Environmental Management Plan.

Measure and monitor vehicle emissions and road dust during Project operation.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on air quality are expected.

| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------|-------------------------|
| Consideration of the airport in air quality assessment | Vancouver International Airport and Boundary Bay Airport were taken into consideration in the assessment of baseline studies for Air Quality. | Addressed | None |
| RAA is too large to properly measure cumulative effects of “intensified” industrial development on the South Arm of the Fraser River. MIB should be consulted directly regarding necessary boundaries. | | | |

4.10 ATMOSPHERIC NOISE

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the highway but do not exceed what is acceptable for residential, educational or institutional facilities.

Effects

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

Mitigation

Minimize effects through Project design.

Adhere to construction best practices and the Ministry’s 2014 *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways*.

Develop and implement a Noise Management Plan.

Noise monitoring program.

Site specific schedules and activities.

Residual & Cumulative Effects

With the application of mitigation, no significant Project-related residual or cumulative effects on air quality are expected.

| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
|-------|---------------------------|--------|-------------------------|
|-------|---------------------------|--------|-------------------------|

| | | | |
|--|--|--|--|
| Musqueam has not voiced specific concerns regarding Atmospheric Noise. | | | |
|--|--|--|--|

5.2 MARINE USE

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, and sorting and booming, as well as commercial, recreational and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place within the vicinity of the Project.

A clear span crossing of the Fraser River is proposed to avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span to improve navigation in and out of the slough.

Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.

Effects

During construction, a measureable effect on access to instream locations for traditional use has been determined.

During construction, a measurable effect on quality of experience tied to access of instream locations for traditional has been determined.

During operation, a negligible effect on access to instream locations for traditional use has been determined.

During construction, a negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Develop and implement a Marine Access Management Plan to ensure that important marine use activities can be reconciled with temporary constraints associated with Project construction.

Establish communications protocols to advise in-stream construction activities.

Ensure appropriate lighting and marking for safe navigation.

Establish navigation protection zones during construction to avoid or minimize impact on marine use.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on marine access are expected.

| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|---|
| <p>Musqueam’s access to the Fraser River and the potential to displace fishing vessels.</p> <p>Potential interference with Musqueam fisheries during bridge construction and decommissioning of the Tunnel and the importance of working closely with Musqueam to ensure negative effects are avoided.</p> <p>Potential effects of construction during fishing season on fishing activities and access to the River.</p> <p>Impacts of Tunnel decommissioning on Musqueam fisheries, specifically as it relates to timing.</p> | <p>Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction. Mitigation of these effects will include the development and implementation of a specific MIB marine use protocol through direct consultation with MIB. Further mitigation can be achieved through the development and implementation of a Marine Access Management Plan for inclusion of the CEMP, establishment of communications protocols, appropriate lighting and marking for safe navigation, and establishment of navigation protection zones during construction.</p> <p>The Ministry understands the importance of working closely with Musqueam to ensure negative effects are avoided.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in 5.2.4 (Marine Use Mitigation Measures)</p> |
| <p>Inappropriateness/ inadequacy of marine users group for consultation with Musqueam</p> <p>Marine users group is not an appropriate format to address Musqueam concerns</p> | <p>The Ministry is continuing to work with Musqueam to better understand how they would like to participate in the development and implementation of mitigation measures in particular, in relation to alternatives to a marine users group. The Ministry has requested Musqueam input to ensure Musqueam’s concerns are discussed and addressed in an appropriate manner and looks forward to obtaining Musqueam’s feedback in this regard.</p> | <p>Ongoing</p> | <p>Ongoing consultation. The Ministry anticipates that plans related to Application Review consultation with Musqueam will be defined in the MoU.</p> |

5.3 LAND USE

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta.

The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect regional growth trends or current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.

Once the new bridge becomes operational, recreational experience in its vicinity is expected to change due to improvements in local air quality, shoreline restoration of Deas Island, and re-vegetation of areas currently supporting highway infrastructure; improved connectivity across the Deas Island Regional Park resulting from removal of the Tunnel portals; and shading adjacent to the bridge, overhead noise, and changes in local viewsapes.

The Project will not result in changes to existing land use beyond small amounts of land, outside of the existing right-of-way, that area required for the Project.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Address temporary effects on existing land use during construction and incorporate land use considerations into a Traffic Management Plan.

Incorporate land use considerations into a Marine Access Management Plan.

Reconnect recreational trails.

Residual & Cumulative Effects

There is a high, short-term probability of disturbance to residential, commercial and industrial land uses.

There is a high, short-term probability of disturbance to recreational uses near the new bridge.

No significant Project-related residual or cumulative effects on marine access are expected.

| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|------------------|---|
| <p>Project will facilitate increased development around the new Bridge and expansion of marina at Deas Slough</p> | <p>The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect overall regional growth trends of current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.</p> | <p>Addressed</p> | <p>None</p> |
| <p>Impacts of staging/laydown areas. Request that the Ministry provide construction parameters to avoid impacting areas around Project footprint.</p> | <p>The Application has been developed with the assumption that all temporary and permanent works will be included within the Project alignment. Potential staging areas that will be made available to the contractor encompass areas within the highway right-of-way that have been previously developed and disturbed.</p> <p>Any temporary or permanent works that are to take place will be subject to applicable permitting requirements, including <i>Water Sustainability Act</i> permitting and archaeological investigation if required. Applications for these permits will include detailed descriptions and locations of works to take place.</p> <p>If the contractor chooses to develop staging areas on sites other than those identified, site-specific environmental permitting and approvals will be obtained by the contractor.</p> | <p>Addressed</p> | <p>Contractor will obtain permits and approvals as required</p> |

5.5 VISUAL QUALITY

The new bridge will add noticeable visual features to the landscape and will change visual conditions adjacent to the Project alignment. Replacement of interchanges also has the potential to change visual conditions of these locations. At distances greater than one kilometer, the bridge deck will merge with the natural landscape and the main visual features will be the bridge towers. Changes in visual quality at interchanges will be minor as visual quality in such areas is currently influenced by existing transportation infrastructure.

Effects

No to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

A measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Minimize effects through Project design.

Use of vegetated buffers to minimize visual effects to residential developments within close proximity to the bridge in Delta.

Residual & Cumulative Effects

There is a moderate, long-term probability of disturbance to visual quality.

No significant Project-related residual or cumulative effects on marine access are expected.

| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---------------------------|--------|-------------------------|
| Musqueam has not voiced specific concerns regarding Visual Quality. | | | |

6.1 HERITAGE RESOURCES

The Project is located in an area where substantial historical development has occurred and the majority of the Project alignment is characterized as having low archaeological potential. No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

No to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

A measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Develop and implement a Heritage Resources Management Plan, which will include a chance find procedure, to avoid impacts to previously unknown heritage resources that may be encountered during Project construction and operation.

Undertake additional archaeological surveys.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on heritage resources are expected.

| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|---------------------------------|--|
| <p>Protection of archaeological and heritage resources, including intangible heritage sites. Protection of cultural and archaeological sites that are known to exist or may be discovered within the Project area</p> | <p>The Ministry acknowledges that protection of archaeological sites as well as intangible heritage sites are of utmost importance to Musqueam. Musqueam has been provided with a comprehensive list of these sites, the Archaeological Overview Assessment, the Archaeological Impact, and Heritage Resources Overview Assessment. Appropriate measures will be taken to ensure the protection of archaeological and heritage resources.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures as outlined in Section 6.1.4 (Heritage Resources Mitigation Measures)</p> |

| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------|---|
| Participation in archaeological fieldwork and review of archaeological draft reports | Musqueam participated in all archaeological field work to date and was provided the opportunity to review draft archaeological reports. | Ongoing | Musqueam will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports. |
| Ministry's archaeological consultant will not work effectively with Aboriginal Groups based on experience on past projects | The Ministry worked with Musqueam to resolve this concern. | Addressed | None |
| Concern with the involvement of certain Aboriginal groups in archaeological fieldwork for the Project. | Schedule B Aboriginal groups were invited to participate in the archaeological component of the Project. | Addressed | None |

7.0 UMAN HEALTH

Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health. The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options. The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased active and public transportation, improved traffic safety, improvement connectivity and access, improved emergency response, and economic development opportunities.

Future Project-related consultation with Aboriginal groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.

Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations, and emergency response.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

During construction, a measureable effect on access to instream locations for traditional use has been determined.

| 7.0 UMAN HEALTH | | | |
|---|---|---------------|--------------------------------|
| <p>During construction, a measurable effect on quality of experience tied to access of instream locations for traditional has been determined.</p> <p>During operation, a negligible effect on access to instream locations for traditional use has been determined.</p> <p>During construction, a negligible effect on quality of experience tied to access of instream locations for traditional has been determined.</p> <p>A negligible effect on access to upland locations for traditional use has been determined.</p> <p>A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.</p> <p><u>Mitigation</u></p> <p>Implement proven mitigation measures, effectively used during construction of projects such as the South Fraser Perimeter Road and Port Mann / Highway 1 Improvement, to ensure that temporary increases in ambient noise levels and air emissions during construction do not result in health effects.</p> <p>Implementation of mitigation measures outlined in Fish and Fish Habitat, Marine Mammals, Vegetation, Terrestrial Wildlife, Air Quality, Atmospheric Noise, Marine Use and Land Use.</p> <p><u>Residual & Cumulative Effects</u></p> <p>No significant Project-related residual or cumulative effects on human health are expected.</p> | | | |
| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
| Consideration of municipal and regional health plans related to human health | Municipal and regional health plans were considered in the assessment of potential Project-related effects on human health, including community and social factors. | Addressed | None |

| 8.0 ACCIDENTS AND MALFUNCTIONS | | | |
|--|---|---------------|--|
| <p>Adherence to the practices and procedures contained in the Construction Environmental Management Plan will minimize the potential for accidents and malfunctions to occur.</p> <p>In general, replacement of the Tunnel with a new crossing and the proposed highway improvements are expected to lower the risk of accidents and malfunctions during highway operations and maintenance.</p> | | | |
| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
| Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations | An Emergency Response and Spill Contingency Plan will outline how construction personnel will prevent, prepare for, respond to, and clean up spills | Addressed | Implementation of mitigation measures outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan) |

| OTHER ISSUES | | | |
|---|---|---------------|--------------------------------|
| Consultation with Cowichan Nation Alliance identified issues outside of the environmental assessment process, Aboriginal Interests, Aboriginal Consultation, Aboriginal Participation and Project-Related Opportunities, and sections of the Application. | | | |
| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
| Concerns related to dredging, potential for increased vessel traffic and larger vessels resulting from Tunnel decommission | Dredging to deepen the river is not a component of this Project and the Ministry is unaware of any plans by others to dredge the river deeper. The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River today. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. This is outlined in Sections 1.1.7.2 (Construction), 4.1 (River Hydraulics) and 4.2 (Water Quality and Sediment) of the Application. | Addressed | None |

APPENDIX J

Penelakut Tribe

1.0 Introduction

Penelakut Tribe engaged directly with the Ministry on the Project and also collectively with Cowichan Tribes, Halalt First Nation and Stz'uminus First Nation as member nations of the Cowichan Nation Alliance. The Ministry provided information and funding directly to Penelakut. However, Cowichan Nation Alliance provided feedback and participated in meetings and fieldwork. Unless noted otherwise, Cowichan Tribe represented Cowichan Nation Alliance in correspondence, meetings and fieldwork. This overview provides information on consultation with Penelakut specifically, and with Cowichan Nation Alliance as applicable to Penelakut.

This appendix provides a summary of the information presented in Part C Aboriginal Consultation (Part C) of the Application for an Environmental Assessment Certificate (the Application) regarding the assessment of effects on Aboriginal Interests. Aboriginal Interests are defined as asserted or determined Aboriginal rights, including title, or treaty rights. This appendix presents the information specific to Penelakut.

The organization of the information presented generally follows Part C and includes the following sections:

- Consultation;
- Community Profile;
- Existing Conditions;
- Potential Effects;
- Mitigation;
- Residual Effects; and
- Summary and Conclusion.

For more detailed information on the effects assessment on Aboriginal Interests related to Penelakut, refer to the following sections of Part C:

- Consultation with Penelakut (**Section 10.1.2.10**);
- Penelakut community profiles (**Section 10.1.1.8**);
- Description of existing Penelakut Aboriginal Interests (**Section 10.1.3.2**);
- Assessment of potential effects of the Project on the exercise of Penelakut Aboriginal Interests (**Section 10.1.3.3**);
- Mitigation relating to potential effects on Aboriginal Interests (**Section 10.1.3.4**); and
- Residual effects on Penelakut Aboriginal Interests following application mitigation (**Section 10.1.3.5**).

A summary of the Aboriginal Interests Assessment for Penelakut is also provided in **Section 10.1.3.8**.

The summary presented in this appendix also incorporated information found in the Penelakut Tribe Overview Table (**Appendix J2**), which provides detailed information regarding:

- Penelakut issues and concerns identified to date;
- Identification of effects on VCs and ICs that relate to the assessment of effects on Penelakut's Aboriginal Interests;
- The Ministry's response to specific issues and concerns raised by Penelakut;
- The status of these issues and concerns; and
- Next steps required to address outstanding issues and concerns.

2.0 Consultation

This section provides information regarding the consultation activities that the EAO and Ministry carried out prior to submission of the Application.

2.1 EAO-led Consultation Activities

2.1.1 Capacity Funding

When a provincial agency is a proponent of a project going through a provincial EA under the British Columbia *Environmental Assessment Act (BCEAA)*, that agency provides funding to Aboriginal Groups to support their involvement in pre-Application and Application review phases in place of EAO providing such funding. The Ministry's provision of capacity funding is discussed in the following section, Proponent-led Consultation Activities.

2.1.2 Participation in Working Group

EAO invited Penelakut and all other Aboriginal groups identified in Schedule B of the Section 11 Order to participate as members of a Working Group.

During the Pre-Application stage, EAO held two Working Group meetings where the Ministry presented information on the Project and the environmental assessment process and received and responded to comments on those presentations. Halalt First Nation represented Cowichan Nation Alliance at the first meeting. Halalt First Nation and Cowichan Tribes represented Cowichan Nation Alliance at the second meeting.

The first Working Group meeting, held January 2016, focused on the environmental assessment process, Project overview and update, Key Areas of Study, draft Application Information Requirements overview, and preliminary conclusions from study results.

The second working group meeting, held March 2016, focused on the environmental assessment process, list of materials available on the Project website, review of comments received on, and resulting changes to, the draft Application Information Requirements, and a description and rationale of the assessment areas. Working Group comments raised by Cowichan Nation Alliance in relation to the draft Application Information Requirements resulted in Aboriginal groups being invited to participate in river-otter related fieldwork in April 2016. The objectives of this work were to document river otter presence or potential presence within the Regional Assessment Area, document and describe use of riparian and high use areas and identify potential Project-related effects.

Cowichan Nation Alliance participated in the completeness review of the Application for an Environmental Assessment Certificate (Application) that considered whether the Application included information requirements set out in the Application Information Requirements.

It is anticipated that Penelakut will continue as an active member of the Working Group through the environmental assessment process.

2.2 Proponent-led Consultation Activities

The Ministry began consultation with Penelakut in early 2014 in order to identify the nature and scope of Penelakut's Aboriginal Interests and how they might be impacted by the Project. Following is a summary of consultation activities led by the Ministry with Penelakut. A more detailed discussion is provided under the Penelakut section in **Section 10.1.2.10 Overview of consultation with each Schedule B Aboriginal Group**. The following sections represent the main activities undertaken in support of Proponent-led consultation and include the following:

- Provision of capacity funding;
- Traditional use, traditional knowledge and other studies;
- Examples of Consultation Activities; and
- Concerns Identified to Date.

2.2.1 Capacity Funding

The Ministry entered into a Participation Funding Agreement, including the Initial Consultation and Pre-Application phases for consultation, with Penelakut. The Ministry has been working with Penelakut regarding their needs for capacity funding to facilitate their participation in the Application Review Phase. Consultation activities that are anticipated to be undertaken during the Application Review phase that will be supported by capacity funding include participation in technical reviews and analyses, involvement in ongoing consultation activities, and presentation of key information regarding their respective Aboriginal Interests.

2.2.2 Traditional Use, Traditional Knowledge & Other Studies

- The Ministry provided additional funding to Penelakut for the preparation and submission of Traditional Use, Traditional Knowledge or other studies. Penelakut worked with other Cowichan Nation Alliance members and submitted the following traditional use studies: *Cowichan Nation Traditional, Current, and Planned Future Use of the George Massey Tunnel Replacement Bridge Project Area, prepared by Candace Charlie for Cowichan Tribes, on behalf of the Cowichan Nation Alliance, August 9, 2015*
- *George Massey Tunnel Replacement Project: Cowichan Occupation and Use of the Project Lands, prepared by Dorothy Kennedy for David Robbins of Woodward and Co., Counsel for the Cowichan Tribes, on behalf of the Cowichan Tribes, August 25, 2015*

Cowichan Nation Alliance also provided to the Ministry: *Historical Geography of Cowichan Land Use and Occupancy Lower Fraser River: Map Series and Report, prepared for Woodward and Company and the Cowichan Tribes by Kenneth G. Brealey, May 31, 2010.*

The purpose of such studies is to identify Aboriginal input and traditional knowledge for inclusion and consideration in the EA. In addition, studies were funded to enhance the Ministry's understanding of Aboriginal Interests and Aboriginal Group's past, present and desired future use as it pertains to the exercise of Aboriginal Interests within the Project area and the potential adverse effects on identified Aboriginal Interests.

2.2.3 Examples of Consultation Activities

A number of consultation activities were undertaken with Penelakut during both the Initial Consultation Phase and the Pre-Application Consultation Phase as follows:

Initial Consultation Phase Activities - The Ministry recognized the importance and value of early engagement with Schedule B Aboriginal Groups and undertook an Initial Consultation Phase prior to the Pre-Application Phase. The Initial Consultation Phase concluded in December 16, 2015 with submission of the Project Description and Key Areas of Study document. The focus of

the Initial Consultation Phase was collection of baseline information and sharing of draft EA-related documents (i.e. Project Description and Key Areas of Study, Application Information Requirements (AIR)). The main consultation activities the Ministry undertook with Penelakut included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Penelakut;
- Funding for Penelakut's participation in Project consultation activities and EA process;
- Penelakut participation in field studies;
- Site visit;
- Review of draft EA documents such as the Project Description and Key Areas of Study, Heritage Resources Overview Assessment/Archaeological Overview Assessment, AIR, Heritage Resources Assessment and Aboriginal Consultation Plan;
- Meetings with Penelakut Chief and Council, staff, consultants, and elders; and
- Response and follow up with Penelakut regarding the identification and resolution of issues.

Pre-Application Consultation Phase Activities - The Pre-Application Consultation Phase began with the filing of the Project Description and Key Areas of Study document on December 16, 2015 and concluded with the submission of the Application. This phase included the issuance of the Section 11 Order, AIR development and collection of baseline information (may include submission of permit applications). The main consultation activities the Ministry undertook with Penelakut included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Penelakut;
- Funding for Penelakut's participation in Project consultation activities and EA process;
- Meetings with Penelakut Chief and Council, staff, consultants, elders and membership and Cowichan Nation Alliance;
- Penelakut participation in fieldwork;
- Penelakut participation in the EA Working Group;
- Review of draft EA documents such as the Application Information Requirements, Aboriginal Consultation Plan, and Aboriginal Consultation Reports; and
- Response and follow up with Penelakut regarding the identification and resolution of issues.

2.2.4 Concerns Identified to Date

As outlined above, Penelakut’s concerns, identified through consultation undertaken to-date, are presented in **Appendix J2 Penelakut Tribe Overview Table**. The Ministry’s response to Penelakut’s key concerns regarding potential impacts on Penelakut’s Aboriginal Interests are outlined below:

Table 1 Concerns Identified to Date

| Concerns Identified to Date | Response |
|---|---|
| Potential impacts to Cowichan Nation Alliance title, Rights and culture. | Potential Project related impacts to Cowichan Nation Alliance title, Rights and culture, the level of effect predicted, and mitigation measures are outlined the Application. The Ministry will continue to consult with Cowichan Nation Alliance to ensure any effects are minimized. |
| Aboriginal participation and Project-related opportunities <ul style="list-style-type: none"> • Potential employment, training, contracting and economic development opportunities • Community preparedness • Cultural recognition and naming • Revenue sharing opportunities from tolling • Re-establishment of a site on ʔəqtinəs/Tl’uqtinus site for residential and/or commercial purposes • Surplus land | The Ministry is committed to working with Penelakut to identify potential employment, training, contracting and economic development opportunities and to identify ways to support community preparedness. The Ministry is exploring opportunities for cultural recognition and naming and will work with Penelakut on these opportunities. The provincial tolling strategy stipulates that revenue from tolling may only be used to defray the costs of designing, constructing, operating and maintaining highways. The Ministry notes Cowichan Nation Alliance’s wish to re-establish a site on ʔəqtinəs/Tl’uqtinus site for residential and/or commercial purposes. As part of the Project, agricultural land will be protected as much as practical. Once the project is completed, there will be a determination of surplus lands, if any, and disposition will follow the appropriate process including consultation |

| Concerns Identified to Date | Response |
|---|--|
| <p>Effects to fish and fish habitat</p> <ul style="list-style-type: none"> • Importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon • Potential effects of pile driving, blasting and underwater noise generated by Tunnel decommissioning and other construction activities | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon, salmon to Penelakut and is committed to avoiding or mitigating any potential effects.</p> <p>The Ministry designed a clear span bridge over the Fraser River South Arm and Deas Slough to avoid or minimize Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat.</p> <p>As outlined in Section 4.3 (Underwater Noise), sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources will be effectively mitigated by scheduling activities during period of low tide, when work can be completed under shallow water conditions or in the dry.</p> |
| <p>Environmental Assessment (EA):</p> <ul style="list-style-type: none"> • Adequacy of methodology to address social and cultural effects • Process and associated timelines • Strength of Claim Assessment | <p>The Ministry acknowledges the importance of Penelakut’s involvement in the environmental assessment process and is committed to funding Penelakut’s participation in the Initiation Consultation and Application Review phases.</p> <p>Penelakut’s concerns related to Environmental Assessment including the adequacy of methodology to address social and cultural effects, process and associated timelines are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> <p>Concerns relating to the Strength of Claim Assessment have been referred to EAO and MARR.</p> |
| <p>Social effects of the Project on Cowichan Nation Alliance’s ability to transfer knowledge, language and participate in socio-cultural practices</p> | <p>Social effects of the Project on Penelakut’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential</p> |

| Concerns Identified to Date | Response |
|---|--|
| | Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of Part C of the Application. |
| <p>Cumulative effects:</p> <ul style="list-style-type: none"> • Consideration of cumulative effects on Aboriginal rights • Absence of comprehensive study on cumulative effects on the Fraser River | <p>The Application includes historical context relating to changes in use over time by Penelakut e and other Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by Penelakut or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests.</p> <p>While the Ministry acknowledges that Penelakut is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project.</p> |
| <p>Concerns related to dredging, potential for increased vessel traffic and larger vessels resulting from Tunnel decommissioning</p> | <p>Dredging to deepen the river is not a component of this Project and the Ministry is unaware of any plans by others to dredge the river deeper. The Project, including the decommissioning of the Tunnel, will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. This is outlined in Sections 1.1.7.2 (Construction), 4.1 (River Hydraulics) and 4.2 (Water Quality and Sediment) of the Application.</p> |
| <p>Potential effects on Fraser River flow rates after Tunnel removal</p> | <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Flow rates are discussed in Section 4.1 (River Hydraulics).</p> |

| Concerns Identified to Date | Response |
|---|---|
| Potential effects of run off and drainage | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected.</p> <p>Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> |

3.0 Community Profile: Penelakut Tribe

Penelakut Tribe is governed by a chief and council with a two-year term under an *Indian Act* electoral system. Penelakut has a 13-member council, with the current term expiring in February 2018.

While the First Nations affiliated with the Cowichan Nation Alliance have explained that they traditionally resided on both sides of the Strait of Georgia as part of a seasonal round, Penelakut's primary village (Penelakut IR 7) is on Penelakut Island, to the east of Chemainus on southeast Vancouver Island. Penelakut members also reside on Kuper, Tent and Galiano islands. Of Penelakut's 952 registered members, 525 live on reserve.. The Project area does not overlap any of Penelakut's current or former reserve lands.

Penelakut is, or has been, affiliated with the Hul'qumi'num Treaty Group, along with the other three Cowichan Nation Alliance members, Lake Cowichan First Nation and Lyackson First Nation. These First Nations have been described as speakers of the "Island" dialect of Halkomelem (*Hul'q'umi'num*), and have referred to themselves collectively as *Hul'qumi'num Mustimuhw*.

The Hul'qumi'num Treaty Group member bands collectively assert a core territory or "title lands" and a wider marine or fishing territory, as described in its Statement of Intent to the British Columbia Treaty Commission. Core areas over which title is asserted include but are not limited to "the south arm of the Fraser River, including Canoe Pass, up to and including Douglas Island, with lands on the north shore of the south arm up to Sapperton Channel (New Westminster), the islands in the south arm of the Fraser River and the south bank of the Fraser River along Canoe Pass up to Deas Island". This area is subsumed within the broader marine or fishing territory. The core territory of the Hul'qumi'num Treaty Group overlaps the Project area at the Tunnel crossing.

Penelakut, along with each of the other Cowichan Nation Alliance member First Nations, has a Forest Consultation and Revenue Sharing Agreement with the Province of British Columbia. The territorial maps attached to these agreements typically include areas on the western side of the Strait of Georgia only.

Locations along the South Arm of the Fraser River of importance to Penelakut, along with the Cowichan Nation Alliance member First Nations, in the vicinity of the Project include but are not limited to *Tl'uqtinus*, spanning the north shore from opposite Deas Island to opposite Tilbury Island, and *Hwlhits'um* or *Xwulit'sum*, on Canoe Pass. Both of these areas are considered by Cowichan Nation Alliance member bands as ancestral village and resource sites. A member

First Nation of the organization has previously reported that the Cowichan Nation Alliance is working to re-establish a permanent land base at *Tl'uqtinus* for residential and/or commercial purposes. Cowichan Nation Alliance's *Tl'uqtinus* claim area is shown in **Section 10.1.3.2 Existing Conditions**.

3.1 Penelakut Tribe Aboriginal Interests: Existing Conditions

This section provides a high level of summary of past, present, and desired future use of the proposed Project area and surroundings for traditional purposes that are or may be connected with the exercise of Penelakut's Aboriginal Interests. A more detailed discussion, including sources used, is provided under Penelakut in **Section 10.1.3.2 Existing Conditions**. In this summary, specific information on Penelakut's traditional use has been supplemented with general information on traditional use by Cowichan Nation Alliance and Hul'qumi'num Treaty Group Nation Alliance member First Nations.

3.1.1 General

- Penelakut has Aboriginal Interests that are known to overlap or lie in the vicinity of the Project corridor, which includes a portion of the South Arm of the Fraser River.
- Penelakut followed a seasonal round of resource use and regional settlement that took them from their winter residences on Vancouver Island and the Gulf Islands across the Strait of Georgia to the Fraser River estuary, where they resided for all or part of the annual salmon runs (April to through October), or, in some instances, year-round. The seasonal round is described in Part C.
- Penelakut has identified past and ongoing effects that have altered and reduced use over time, constraining the current exercise of their Aboriginal Interests.
- A Cowichan Nation Alliance member First Nation has previously reported that the Cowichan Nation Alliance is working to re-establish a permanent land base at *Tl'uqtinus* for residential and/or commercial purposes.

3.1.2 Fishing

- Penelakut harvested the following species historically on the South Arm of the Fraser River: sockeye and pink salmon, sturgeon, shellfish, and marine mammals. Cowichan Nation Alliance has previously reported that now filled-in sloughs and streams in or near Highway 99 once supported coho and eulachon, which were also harvested while they were resident on the Fraser River.
- Cowichan Nation Alliance reports that *Tl'uqtinus* was used seasonally for harvesting purposes, with Halalt reporting that they used the area specifically in July to fish for sockeye and pink salmon. Penelakut also used other habitation sites in the area,

including ones at the southern extent of No. 4 Road, and on a little bay just below Brunswick Point, on the south side of the western entrance to Canoe Pass.

- Areas within the wider Fraser River estuary were also utilized by *Hul'q'umi'num*'-speaking peoples for fishing salmon, sturgeon, groundfish, and other marine resources on the foreshore (e.g., Tsawwassen, Point Roberts, Boundary Bay). Certain species (e.g., sockeye and pink salmon, sturgeon, eulachon, trout, flounder) could only be obtained in, or were preferred to be taken at, Fraser River-based locations.
- The Hul'q'umi'num Treaty Group have reported that during the reserve creation era in the late nineteenth century, government officials were aware of *Hul'q'umi'num Mustimuhw* fishing interests at the Fraser River; however, no reserves were set aside for them in the area. The Hul'q'umi'num Treaty Group have also reported that government regulations introduced in the same era had the effect of restricting their access to fishing in the Fraser River. Despite these changes, *Hul'q'umi'num Mustimuhw* say they continued to use the Fraser River for fishing, including commercially, into the early twentieth century.
- Member First Nations of the Cowichan Nation Alliance have been attempting to restore former fisheries within the Fraser River through Fisheries and Oceans Canada (DFO). Access to sockeye for member First Nations is said to be provided by DFO annually in Johnstone Strait and “off the mouth of the Fraser River”. In the vicinity of the Project area, however, access has been subject to negotiations with First Nations local to the lower Fraser River, and has been limited, occurring only in 2005, 2006, and 2008. In those years, the specific locations in the South Arm in which member First Nations of the Hul'q'umi'num Treaty Group fished for food, social, and ceremonial (FSC) purposes under communal licences was below the Port Mann Bridge generally, as well as specifically, on some occasions, below the easterly point of Kirkland Island (i.e., downstream of the Project area). The Cowichan Nation Alliance has stated that it is in ongoing, active litigation over its asserted fishing rights on the South Arm of the Fraser River.
- The Hul'q'umi'num Fisheries Limited Partnership (HFLP) is a commercial fishing business in which some of the Cowichan Nation Alliance member groups participate (Halalt, Penelakut, and Stz'uminus). Species harvested through this enterprise are crab, prawn, halibut, herring, rockfish, sablefish, and salmon.

3.1.3 Hunting/Trapping

- Cowichan Nation Alliance has previously reported that Highway 99 was built on what was once a prime harvesting location for deer, ducks, and geese, among other species.
- Canada goose, northern shoveler, and green-winged teal would have been available to the Cowichan people year-round.
- The south shore of Lulu Island, along the South Arm of the Fraser River, has been reported as a prime spot for trapping beaver, mink, and muskrat; bear, grouse, elk, squirrel, and porcupine were also hunted by the Cowichan people on the South Arm.

The Cowichan Nation Alliance as a group has stated a desire to resume the harvest of traditional resources in the Project area.

- Cowichan Nation Alliance has also stated that its members revere bald eagles, which were not hunted. Their Elders have indicated that eagle numbers in the Richmond area have been dwindling each year. Breeding habitat along the Highway 99 corridor on Lulu Island has been previously noted.

3.1.4 Gathering

- Cowichan Nation Alliance report that in the marshy areas south of Canoe Passage near Brunswick Point – in the area of *Xwulits'um*, or place for cutting (cattails) – as well as in the area of *Tl'uqtinus* and across the Fraser River on Tilbury Island, several varieties of cattails and rushes (*stth'equn*) were once harvested.
- Berries and other plants were gathered and cultivated by the ancestors of the Cowichan Nation Alliance member bands at *Tl'uqtinus*, and were harvested from other locations in the Project area. These plants included wild rose, rose hips, crabapples, elderberries, horsetail, labrador tea, Indian hemp, trembling aspen, mock orange, oregon grape, maple leaves, cranberries, blueberries, blackberries, wapato, bulrushes/reeds (*stth'equn*), as well as seaweed. With respect to berry plants at *Tl'uqtinus* specifically, a 1979 map produced by Environment Canada noted an “Indian residence” at this location, accompanied by the caption (not attributed to any specific Aboriginal group): “It is known that the Indians who lived here for several thousand years harvested berries from the bogs and used fire to maintain open areas for the berry bushes by preventing encroachment from pine trees”.
- Cowichan Nation Alliance has indicated that they wish to see existing bogs on Lulu Island near the Highway 99 corridor – specifically, one near Williams Road (which runs perpendicular to Highway 99) and another near the Richmond Nature Park (bisected by Highway 99 at Westminster Highway) – protected to support future use of traditional resources, like berries and other bog ecosystem flora. At *Tl'uqtinus*, which is currently surrounded by blueberry farms, Cowichan Nation Alliance has raised the potential for their former berry grounds to be re-established.

3.1.5 Archaeology and Cultural Heritage Interests

- Locations along the South Arm of the Fraser River of importance to the Penelakut in the vicinity of the Project include, but are not limited to, *Tl'uqtinus*, spanning the north shore from opposite Deas Island to opposite Tilbury Island, and *Hwlhits'um* or *Xwulit'sum*, on Canoe Pass. Both of these areas are considered by Cowichan Nation Alliance member bands as ancestral village and resource sites.
- Penelakut has specifically noted the importance of archaeological site DgRs-17.

3.1.6 Other Related Interests

- Cowichan Nation Alliance has stated that it asserts Aboriginal title to *Tl'uqtinus*, and given where *Tl'uqtinus* is reportedly situated, to the Project footprint. The Cowichan Nation Alliance has expressed its view that this title includes the right to manage the land, determine the uses to which it can be put, and obtain any economic benefits from it. Cowichan Nation Alliance has advised that it is also working to re-establish culturally integral practices (e.g., harvesting fish, waterfowl, plants) on the South Arm and at the mouth of the Fraser River, including at and about *Tl'uqtinus*.
- The Cowichan Nation Alliance has previously reported that for the last generation its member First Nations have been rejuvenating their access to the waterways that once served as the highways for their ancestors, working with the currents and tides to travel for FSC purposes. The Cowichan Nation Alliance has expressed concern regarding the contaminants and the sustainability of vital habitats that are necessary to support their members.

4.0 Potential Effects

This section provides a summary of the methodology used to identify potential adverse effects of the proposed Project on the exercise of Aboriginal Interests by Aboriginal Groups during Project construction and operation, followed by a summary of potential effects on Penelakut's Aboriginal Interests, specifically. For a more detailed description, refer to **Section 10.1.3.3.**

Potential Effects.

4.1 Methodology for Identification of Potential Effects

The first step in the effects assessment on Aboriginal interests was the identification of potential adverse effects on traditional use activities and related interests as a result of Project construction or operation. To evaluate these potential adverse effects, the findings of the following Valued Component (VC) chapters in Part B of the Application were considered, including identified mitigation measures, residual effects, cumulative effects and follow up strategies:

- **Section 4.4 Fish and Fish Habitat**
- **Section 4.6 Marine Mammals**
- **Section 4.7 Vegetation**
- **Section 4.8 Terrestrial Wildlife**
- **Section 5.2 Marine Use**
- **Section 5.3 Land Use**
- **Section 5.5 Visual Quality**

- **Section 6.1 Heritage Resources**
- **Section 7.1 Human Health**

The findings of the following Intermediate Component (IC) chapters were also considered in the assessment:

- **Section 4.1 River Hydraulics and River Morphology**
- **Section 4.2 Sediment and Water Quality**
- **Section 4.9 Air Quality**
- **Section 4.10 Atmospheric Noise**

The assessment of potential adverse effects of the Project on the exercise of Aboriginal Interests, including measures to address those effects, are presented in **Section 10.1.3.3** through **Section 10.1.3.5**, and largely applies the same methods used in Part B of the Application for the IC and VC assessments, as outlined in **Section 3.0 Assessment Methodology**.

In addition to information from the VC and IC assessments that support the assessment of potential effects on Aboriginal Interests, information from a Health Impact Assessment (HIA) undertaken to support Project planning, including mitigation recommendations, has been integrated into the assessment of potential effects on Aboriginal Interests. The HIA for the Project can be found at <https://engage.gov.bc.ca/masseytunnel>. A summary of the key findings is provided in **Section 7.2 Health Impact Assessment**.

4.2 Selection of Indicators

Four parameters were chosen as indicators to understand and evaluate potential Project-related effects on the exercise of Aboriginal Interests. The rationale for their selection is presented in the following table.

Table 2 Indicators for the Aboriginal Interests Assessment

| Indicator | Rationale for Selection |
|---|---|
| Access to preferred locations for the exercise of Aboriginal Interests | Project components or activities could result in changes in access to or patterns of travel between traditional use locations on land or water |
| Availability of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in distribution or movement, relative abundance, or habitat area or composition of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in the real or perceived quality of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests | Project components or activities could result in: (1) direct sensory disturbance to traditional users (e.g., from noise, vibration); and/or (2) indirect changes to cultural practices, customs or traditions – i.e., cultural heritage or the expression and transfer of cultural values or ways of knowing (e.g., language, laws/governance, stories, spiritual beliefs) – tied to the cultural landscape or to the traditional use of specific traditional use locations or resources within that landscape. |

Potential adverse effects on the indicators noted above were analyzed in terms of the type and level of effect that Project components and activities may be expected to have on the exercise of Aboriginal Interests.

For the purposes of this assessment, no effect was understood to mean that no interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests would be expected. Where it was determined that an interaction, and potential effect, could occur, the following definitions were used to guide the characterization of the effect as negligible or measurable:

- Negligible – An interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests may occur, but modifications to the use of preferred options would not be expected.

- Measurable – Modifications to the exercise of Aboriginal Interests at preferred locations or in relation to preferred resources may be needed, and may be considered to be:
 - Minor (minimal or temporary modifications may be required to use preferred options),
 - Moderate (more frequent or longer term modifications may be required to use preferred options), or
 - Serious (permanent or indefinite modifications may be required potentially resulting in the loss of preferred options).

4.3 Identified Potential Effects

As noted above, the first step in evaluating potential adverse effects on Aboriginal Interests was a consideration of the findings for relevant Part B VCs, including identified mitigation measures, residual effects, cumulative effects and follow up strategies. The residual effects with the potential to result in an adverse effect on Aboriginal Interests are then carried forward in the assessment. Using the four indicators noted in the previous section, the potential Project-related effects and level of effect predicted in relation to Penelakut's exercise of Aboriginal Interests remaining after Part B mitigation are as follows:

Table 3 Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|---|--------------|------------|------------|------------|----------------------------|
| | Negligible | Measurable | Negligible | Measurable | |
| River locations for traditional use as a result of changes to physical characteristics of these locations | ✓ | | ✓ | | |
| Instream locations for traditional use | ✓ | | ✓ | | |
| Upland locations for traditional use | ✓ | | ✓ | | |

Table 4 Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|--|--------------|------------|------------|------------|----------------------------|
| | Negligible | Measurable | Negligible | Measurable | |
| Fish resources for traditional use | ✓ | | ✓ | | |
| Marine mammal resources for traditional use | ✓ | | ✓ | | |
| Terrestrial wildlife resources for traditional use | ✓ | | ✓ | | |
| Vegetation resources for traditional use | ✓ | | ✓ | | |

Table 5 Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |

| Terrestrial wildlife resources for traditional use | ✓ | | ✓ | | |
| Vegetation resources for traditional use | ✓ | | ✓ | | |
| Air quality | ✓ | | ✓ | | |
| Noise | ✓ | ✓ | ✓ | ✓ | Construction - Potential temporary direct (minor) effect on quality of experience related to construction-related noise. Operation - Potential permanent direct (minor) effect on quality of experience related to traffic noise |
| Ground-borne vibration | ✓ | | ✓ | | |

| | Construction | | Operation | | Residual Potential Effects |
|--------------------|--------------|------------|------------|------------|---|
| | Negligible | Measurable | Negligible | Measurable | |
| Cultural landscape | | ✓ | | ✓ | <p>Construction - Potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance</p> <p>Operation - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses.</p> |

4.4 Potential Project-Related Effects on Penelakut's Aboriginal Interests

Using the methodology presented in **Section 10.1.3.3 Potential Effects**, Table 7 provides the potential incremental Project-related effects, following mitigation of Project-related effects on Part B VCs and ICs as described in Part B, related to Penelakut's Aboriginal Interests as summarized in Existing Conditions were identified for Project Construction and Operation. A discussion of potential Project-related effects on fishing, hunting/trapping, gathering and archaeology and cultural heritage follows the table.

Table 7 Summary of Potential Project-Related Effects

| Indicator | Potential Project-Related Effect |
|---|---|
| Project Construction | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> None identified |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> None identified |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> None identified |

| Indicator | Potential Project-Related Effect |
|--|---|
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • Potential temporary direct (minor) effect on quality of experience related to construction-related noise • Potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance |
| Project Operation | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • Potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses • Potential permanent direct (minor) effect on quality of experience related to traffic noise • Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses |

4.5 Fishing

Penelakut harvested the following s historically on the South Arm of the Fraser River included sockeye and pink salmon, sturgeon, shellfish, and marine mammals. Cowichan Nation Alliance has previously reported that now filled-in sloughs and streams in or near Highway 99 once supported coho and eulachon, which were also harvested while resident on the Fraser River. Certain species (e.g., sockeye and pink salmon, sturgeon, eulachon, trout, flounder) could only be obtained in, or were preferred to be taken at, Fraser River-based locations. Member First Nations of the Cowichan Nation Alliance have been attempting to restore former fisheries within the Fraser River through Fisheries and Oceans Canada (DFO).

The proposed Project has the potential to affect fishing practices through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred fishing locations by Penelakut, as a result of changes in river hydraulics or morphology, are expected to be negligible before mitigation. Potential changes in access to instream locations for fishing by Penelakut during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to fishing locations by Penelakut from instream construction activities are expected to be negligible. While it is acknowledged that Cowichan Nation Alliance has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Mitigation measures identified in the fish and fish habitat assessment to address Project-related effects on fish are expected to be effective at addressing potential effects on the availability of fishing resources preferred by Penelakut. Further, as residual effects on fish identified in the fish and fish habitat assessment are not anticipated to affect population integrity, potential residual effects as a result of Project construction activities, would not be expected to measurably affect the availability of preferred fish resources.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of fishing resources preferred by Penelakut; therefore, Potential Project-related effects on Penelakut fishing would be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when fishing are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in in Section 4.10 Atmospheric Noise are expected to largely address a potential Project-related effect to the quality of experience while fishing. At preferred fishing locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Penelakut.

Section 5.5 Visual Quality predicts that residual effects to visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Penelakut is fishing. As this landscape has been previously modified, the potential Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Penelakut's Aboriginal Interests related to fishing are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.6 Hunting/Trapping

Cowichan Nation Alliance reported that Highway 99 was built on what was once a prime harvesting location for deer, ducks, and geese, among other species. Canada goose, northern shoveler, and green-winged teal would have been available to the Cowichan people year-round. The south shore of Lulu Island, along the South Arm of the Fraser River, has been reported as a prime spot for trapping beaver, mink, and muskrat; bear, grouse, elk, squirrel, and porcupine were also hunted by the Cowichan people on the South Arm.

The proposed Project has the potential to affect hunting and trapping through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred hunting and trapping locations by Penelakut as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for hunting and trapping by Penelakut during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to hunting and trapping locations by Penelakut from instream construction activities, are expected to negligible. While it is acknowledged that Cowichan Nation Alliance has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for hunting and trapping by Penelakut resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with hunting and trapping locations.

Mitigation measures identified in the marine mammal and terrestrial wildlife assessments are expected to be effective at addressing potential effects on the availability of hunting and trapping resources preferred by Penelakut. Therefore, Project-related effects on hunting and trapping related to potential changes in the availability of resources would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for hunting and trapping by Penelakut; therefore, Potential Project-related effects on Penelakut fishing would be expected to be negligible.

Project operation is not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when hunting and trapping are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** to address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while hunting and trapping. At preferred hunting and trapping locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Penelakut.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Penelakut is hunting and trapping. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Penelakut's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.7 Gathering

Cowichan Nation Alliance report that in the marshy areas south of Canoe Passage near Brunswick Point – in the area of *Xwulits'um*, or place for cutting (cattails) – as well as in the area of *Tl'uqtinus* and across the Fraser River on Tilbury Island, several varieties of cattails and

rushes (*stth'equn*) were once harvested. Berries and other plants were gathered and cultivated by the ancestors of the Cowichan Nation Alliance member bands at *Tl'uqtinus*, and were harvested from other locations in the Project area. These plants included wild rose, rose hips, crabapples, elderberries, horsetail, labrador tea, Indian hemp, trembling aspen, mock orange, oregon grape, maple leaves, cranberries, blueberries, blackberries, wapato, bulrushes/reeds (*stth'equn*), as well as seaweed. Tree species available in the vicinity of the Fraser River and traditionally used by the Cowichan Tribes for manufacturing include crabapple, willow, alder, cottonwood, cedar, spruce, aspen, yew, hemlock, and vine maple.

The proposed Project has the potential to affect gathering through changes in access to preferred locations, changes in availability of preferred resources, changes in quality of preferred resources and changes in quality of experience when gathering.

Potential changes in access to preferred gathering locations by Penelakut as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for gathering by Penelakut during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to gathering locations by Penelakut from instream construction activities, are expected to be negligible. While it is acknowledged that Cowichan Nation Alliance has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for gathering by Penelakut resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with gathering locations.

Mitigation measures identified in the vegetation assessment to address Project-related effects on terrestrial vegetation are expected to be effective at addressing potential effects on the availability of resources for the exercise of Aboriginal Interests related to gathering. Therefore, Project-related effects on gathering related to potential changes in the availability of vegetation would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for gathering by Penelakut; therefore, Potential Project-related effects on gathering related to potential changes in the quality of resources would therefore be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when gathering are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while gathering. At preferred gathering locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Penelakut.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Penelakut is gathering. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Penelakut's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.8 Archaeology and Cultural Heritage Interests

Locations along the South Arm of the Fraser River of importance to the Penelakut in the vicinity of the Project include, but are not limited to, *Tl'uqtinus*, spanning the north shore from opposite Deas Island to opposite Tilbury Island, and *Hwlhits'um* or *Xwulit'sum*, on Canoe Pass. Both of these areas are considered by Cowichan Nation Alliance member bands as ancestral village and resource sites.

The proposed Project has the potential to affect Penelakut’s Aboriginal Interests related to archaeology and cultural heritage through changes in access to preferred locations and changes in quality of experience.

Potential changes in access to locations related to Penelakut’s archaeological and cultural heritage interests as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations related to Penelakut’s interests related to archaeology and cultural heritage during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to locations related to Penelakut’s archaeological and cultural heritage interests from instream construction activities are expected to be negligible. While it is acknowledged that Cowichan Nation Alliance has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations related to Penelakut’s archaeological and cultural heritage interests resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and not expected to overlap with locations related to Penelakut’s archaeological and cultural heritage interests.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** would also be expected to address the potential Project-related effect to the quality of experience while undertaking activities related to cultural heritage. At locations related to Penelakut’s archaeological and cultural heritage interests that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Penelakut.

As reported in **Section 6.1 Heritage Resources**, no archaeological or historical sites were identified within the Project area during fieldwork; however, there may be other locations with intangible cultural value or meaning to Penelakut (e.g., spiritual or storied sites, named places) potentially affected by the Project. In addition, physical alterations to the landscape may affect archaeological or historical sites, and how this landscape is experienced culturally.

As a result, mitigation measures proposed in Part B are not expected to address a potential incremental and permanent Project-related effect tied to Penelakut's Aboriginal Interests related to archaeology and cultural heritage that may be associated with the introduction of a new prominent feature to the cultural landscape. As this landscape has been previously modified by anthropogenic changes, the potential incremental Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal, but permanently disruptive for Penelakut, who have identified a historical connection to, and continued or desired use of, sites or places that help define the cultural landscape in the Project area.

Additional mitigation to address this potential incremental effect that is not otherwise addressed in the Application is proposed in **Section 10.1.3.4** and summarized below under Mitigation.

5.0 Mitigation

This section provides a summary of mitigation measures identified to address potential Project-related effects on the exercise of Aboriginal Interests by Penelakut. For a more detailed discussion, refer to **Section 10.1.3.4 Mitigation**.

Mitigation measures identified for the relevant VCs and ICs in Part B of the Application were reviewed to assess their effectiveness at addressing potential Project-related effects on the exercise of Aboriginal Interests related to those VCs. Examples of mitigation that are proposed in the Application to address potential effects on VCs and ICs, with the potential to result in an effect on Aboriginal Interests, include:

- Avoiding fisheries sensitive timing windows during key Project activities.
- Developing a Marine Access Management Plan to ensure marine use activities, including those supporting Aboriginal Interests, can continue during Project construction.
- Scheduling activities with the potential to generate underwater noise to avoid potential effects on marine mammals.
- Development and implementation of a Terrestrial Vegetation and Wildlife Management Plan with measures to minimize disturbance and loss of vegetation, prevent soil compaction, and minimize clearing in order to minimize effects on vegetation.

These measures are expected to be largely effective at avoiding, reducing, or otherwise managing potential Project-related effects on the exercise of Aboriginal Interests during Project construction and operation.

Recognizing some measurable effects on Penelakut’s Aboriginal Interests could remain following the application of mitigation to address potential effects on the relevant VCs and ICs in Part B, the following additional measures have been identified to address such effects:

- Ongoing consultation with Penelakut regarding proposed measures, management plans, and monitoring programs related to intermediate components and valued components assessments; and
- Development of a Cultural Heritage Management Plan.

6.0 Residual Effects

With the implementation of mitigation measures identified in Section 10.1.3.4 and summarized above, residual adverse effects of the proposed Project on the exercise of Aboriginal Interests are expected to be negligible (i.e., not measurable or detectable), and are not further assessed.

7.0 Summary and Conclusion

Part C of the Application builds on consultation undertaken to date to understand Penelakut’s Aboriginal Interests and provides for an assessment of potential Project-related effects of the Project on Aboriginal Interests.

The Ministry began consultations with Penelakut prior to the submission of the Project Description, which is the end of the Initial Consultation Phase. Both EAO and the Ministry consulted with Penelakut during the Pre-Application Phase, which concluded with the submission of the Application. The main concerns expressed by Penelakut during consultations include:

- Potential impacts to Penelakut title, rights and culture;
- Consideration for future uses should include Penelakut’s plans;
- Aboriginal participation and Project-related opportunities (e.g., potential employment, training, contracting and economic development opportunities);
- Potential effects to air quality, particularly in relation to terrestrial wildlife;
- Effects to fish and fish habitat, and importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon;
- Potential effects of pile driving, blasting and underwater noise generated by Tunnel decommissioning and other construction activities;
- Adequacy of EA methodology to address social and cultural effects;
- EA process and associated timelines;
- Strength of claim;

- Social effects of the Project on Penelakut's ability to transfer knowledge, language and participate in socio-cultural practices;
- Cumulative effects;
- Concerns related to dredging, potential for increased vessel traffic and larger vessels resulting from Tunnel decommissioning;
- Potential effects on Fraser River flow rates after Tunnel removal; and
- Potential effects of run off and drainage.

Based on information provided by Cowichan Nation Alliance and other publicly-available sources, the Ministry developed a summary of past, present and desired future use of the proposed Project area and its surroundings for the purposes of fishing, hunting/trapping, gathering, archaeology and cultural heritage interests and other related interests. This summary indicates that Penelakut has, does and intends to continue to use the Fraser River for cultural purposes.

Relying first on the results of the effects assessments for related VCs and ICs in Part B, the assessment of potential effects of Penelakut's Aboriginal Interests considered four indicators:

1. Access to preferred locations for the exercise of Aboriginal Interests;
2. Availability of preferred resources for the exercise of Aboriginal Interests;
3. Quality of preferred resources for the exercise of Aboriginal Interests; and
4. Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests.

As reviewed in **Section 10.1.3.3** and **Section 10.1.3.4**, the mitigation measures, management plans, and monitoring programs identified in Part B of the Application for ICs or VCs linked to the exercise of Aboriginal Interests are expected to be largely effective at addressing the incremental Project-related effects noted above on the exercise of Aboriginal Interests by Penelakut, except in the following potentially measurable cases:

- Project construction:
 - Potential temporary direct (minor) effect on quality of experience related to construction-related noise and a potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance

- Project operation:
 - Potential permanent direct (minor) effect on quality of experience related to traffic noise and a potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses
 - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses.

The following additional measures have been identified to address the above-noted effects:

- Ongoing consultation with Penelakut regarding proposed measures, management plans, and monitoring programs related to VC and IC assessments; and
- Development of a Cultural Heritage Management Plan.

With the implementation of mitigation proposed to address potential effects on VCs and ICs, as well as additional mitigation proposed to address potential residual effects on Aboriginal Interests, no effects on the exercise of Aboriginal Interests by Penelakut, as a result of the Project, are expected.

ENVIRONMENTAL ASSESSMENT PROCESS

An environmental assessment of the Project is required under the B.C. Environmental Assessment Act (B.C. EAA), S.B.C. 2002, c. 43, and permits to construct and operate can only be received once the environmental assessment process is complete and an Environmental Assessment Certificate (EAC) has been issued. If the Project is approved, an EAC will be awarded to and held by the Ministry. The Reviewable Projects Regulation B.C. Reg. 370/2002 under the B.C. EAA sets out the criteria for reviewable projects.

On December 16, 2015, the B.C. Environmental Assessment Office (EAO) issued a Section 10(1)(c) Order confirming that the Project is a reviewable project pursuant to the B.C. EAA, and that it requires an EAC.

The Project as proposed is not subject to review under the Canadian Environmental Assessment Act, 2012, S.C. 2012, c. 19, s. 52, since it does not meet the definition of a physical activity under the Schedule of Physical Activities in the Regulations Designating Physical Activities SOR/2012-147.

EAO is a neutral agency that manages the review of proposed major projects in British Columbia, as required by the Environmental Assessment Act.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------------|-------------------------|
| Social and cultural effects and the adequacy of EA methodology | <p>Concerns related to the adequacy of Environmental Assessment are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> <p>Social and cultural effects of the project are considered in Part C of the Environmental Assessment Application (Application). Where Aboriginal Groups values and perspectives have been provided to the Proponent regarding environmental, economic, social, heritage or health valued components (VCs), they have been incorporated, where applicable into the Part B assessment of those VCs.</p> | Referred to EAO | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------------------------|--------------------------------------|
| Strength of Claim assessment and related depth of consultation. | Concerns related to the strength of claim assessment have been referred to EAO and MARR. | Referred to EAO and MARR | None |
| Project's EA Process and its associated timelines. | Concerns relating to the EA process and its associates timelines were referred to EAO. EAO issued a memo to members of the Working Group on March 18, 2016 in response to questions and concerns related to the EA process and its associated timelines. The Ministry understands that EAO responded to Penelakut Tribe's queries regarding the EA Process and associated timelines. | Referred to EAO | None |
| Effectiveness and nature of the EA process as well as current volume of EAs underway | Concerns relating to the broad concern related to the effectiveness and nature of the Environmental Assessment Process have been referred to EAO. While the Ministry is unable to address the concern related to the current volume of EA's underway, the Ministry has and will continue to work with Penelakut Tribe to support their participation in this particular Project's review process and to plan for consultation activities in a manner that is mindful of the current volume of referrals that Penelakut Tribe is working on. Support to date has included Pre-Application capacity funding. | Referred to EAO | None |
| Lack of resources and funding for First Nations communities. | The Ministry provided funding for the Pre-Application Phase and has committed to providing funding for the Application Review Phase. | Addressed | Funding for Application Review Phase |

ABORIGINAL INTERESTS

There are potential Project related impacts to Penelakut Tribe's title, Rights and culture. Potential effects and the level of effect predicted include:

1. Access to preferred locations for the exercise of Aboriginal Interests (access to river locations for traditional use as a result of changes to physical characteristics of these locations).
2. Availability of preferred resources for the exercise of Aboriginal Interests (availability of fish, marine mammal, vegetation and terrestrial wildlife resources for Traditional Use).
3. Quality of preferred resources for the exercise of Aboriginal Interests (quality of water used for cultural purposes, quality of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use).
4. Quality of experience of exercising, or tied to the exercise, of Aboriginal Interests (quality of experience tied to the traditional use of river locations as a result of changes to the physical characteristics of the location; quality of experience tied to access of instream and upland areas locations for traditional use; quality of experience tied to use of water for traditional purposes; quality of experience tied to the traditional use of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use; and quality of experience while engaged in or tied to traditional use as a result of changes in air quality, noise, ground-borne vibration and to the cultural landscape).

Measureable Effects

Access for traditional use

- Cultural landscape

Quality of experience while engaged in or tied to traditional use

- cultural landscape

No, Negligible or Moderate Effects

Quality of experience while engaged in or tied to traditional use

- Noise

Negligible Effects

Access for traditional use

- Instream locations
- River locations
- Upland locations

ABORIGINAL INTERESTS

Quality for Traditional Use

- Water
- Fish resources
- Marine mammal resources
- Vegetation resources

Quality of experience while engaged in or tied to traditional use

- Fish resources
- Instream locations
- Marine mammal resources
- River locations
- Terrestrial wildlife resources
- Upland locations
- Water
- Vegetation resources

Availability for Traditional Use

- fish resources
- Marine mammal resources
- Terrestrial wildlife resources
- Vegetation resources

No to Negligible Effects

Quality of experience while engaged in or tied to traditional use

- changes to the cultural landscape

No or Negligible Effects

Quality of experience while engaged in or tied to traditional use

- Air quality
- Ground-borne vibration

ABORIGINAL INTERESTS

High, Short-term Probability of Effect

- Disturbance to residential, commercial and industrial land uses
- Disturbance to recreational uses near the new bridge

Moderate, Long-term Probability of Effect

- Disturbance to visual quality

Low, Short-term Probability of Effect

- Barn swallow habitat loss (construction period)
- Physical injury or mortality to fish through crushing or entrainment (construction period)

Low, Long-term Probability of Effect

- Barn owl mortality

No Significant Residual or Cumulative Effects

- Air quality
- Fish and fish habitat
- Heritage resources
- Marine access
- Marine mammals
- River hydraulics and river morphology
- Sediment and water quality
- Terrestrial Wildlife
- Vegetation

The Ministry has developed mitigation measures to address these Potential effects. Residual effects on the exercise of Aboriginal Interests by Penelakut Tribes as a result of the Project are not expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Potential impacts to Penelakut Tribe’s title, Rights and culture. Identification of future developments should include potential Penelakut Tribe’s title and rights resulting from treaty negotiations or proof of title.</p> | <p>Potential Project related impacts to Penelakut Tribe’s title, Rights and culture, the level of effect predicted, and mitigation measures are outlined the Application. The Ministry will continue to consult with Penelakut Tribe to ensure any effects are minimized.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in all Sections of the Application</p> |
| <p>Identification of “other requirements that are relevant to the Project, including international agreements or other agreements” should be included in the Crown’s Constitutional obligations to First Nations“</p> | <p>The Crown’s constitutional obligations are fundamental to consultation with Penelakut Tribe and the EA process. The obligations within the context of the EA are addressed in Part C of the Application.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation</p> |
| <p>“Consideration for future uses should include Cowichan Nation Alliance’s plans to re-establish a site on λəqtinəs/Tl’uqtinus site for residential and/or commercial purposes.”</p> | <p>Noted</p> | <p>Noted</p> | <p>Ongoing consultation</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|---|
| <p>Penelakut Tribe’s access to the Fraser River and the potential to displace fishing vessels. Potential interference with Aboriginal fisheries during decommissioning of the Tunnel.</p> | <p>Penelakut Tribe’s access to the Fraser River and the potential to displace fishing vessels (access to river locations for traditional use as a result of changes to physical characteristics of these locations) is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined. A measurable direct effect on access to instream locations for traditional use and a negligible effect to upland locations for traditional use has been determined.</p> | <p>Addressed</p> | <p>Ongoing consultation and implementation measures outlined in Section 5.2.4</p> |
| <p>Social effects of the Project such as Penelakut Tribe’s knowledge transmission, language loss, dependency and social interaction.</p> | <p>Social effects of the Project on Penelakut Tribe’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation measures outlined in all sections of the Application</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| | <p>predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of the Application.</p> | | |
| <p>Protection of Penelakut Tribe’s rights to harvest within the Project area.</p> | <p>Penelakut Tribe’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures outlined in Table 10.3-1 and Section 10.1.3.4, residual effects on the exercise of Aboriginal Interests by Penelakut Tribe as a result of the Project are not expected.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and Implementation of measures outlined in Section 10.1.3.4</p> |
| <p>Assessment of cumulative effects in regards to the inclusion of other reasonably foreseeable projects and activities.</p> | <p>The Ministry’s cumulative effects assessment looked at potential incremental environmental effects of construction and operation of the Project in conjunction with other present and reasonably foreseeable projects that could interact with the potential effects of this Project. The process and methodology used to conduct the cumulative effects assessment, including the identification of potential cumulative effects, identification of additional mitigation measures, and evaluation of any (residual) cumulative effects is outlined in Part B of the Application. Other Projects that are considered in the assessment of Project-related cumulative effects are also listed.</p> | <p>Addressed</p> | <p>None</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|-----------|-------------------------|
| Concern that the overlapping construction period of GMT and Pattullo projects needs to be considered in the assessment. | Rehabilitation of the Pattullo Bridge will be completed by October 2016. The replacement of the Pattullo bridge is in planning stages and a construction period has yet to be established. | Addressed | None |
| Consideration of cumulative effects on aboriginal rights, including measurement against a pre-industrial baseline | The Application will include historical context as outlined relating to changes in use over time by Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by First Nations or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests. | Addressed | None |
| Absence of a comprehensive study of cumulative effects on the Fraser River | While the Ministry acknowledges that Penelakut Tribe is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project. | Addressed | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|-----------|-------------------------|
| Length of time tolls are in place | <p>The Province intends to fund the Project, at least in part, through user tolls. This is consistent with the provincial tolling guidelines. Tolling recognizes that those directly benefitting from the new infrastructure in terms of time savings and reliability should help pay for the Project. This ensures that the needed improvements can proceed now, rather than years in the future when improvements will be even more overdue. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application.</p> | Addressed | None |
| Revenue sharing opportunities from tolling | <p>Revenue from tolling is only used to defray the costs of designing, constructing, operating and maintaining highways. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application.</p> | Addressed | None |

| ABORIGINAL CONSULTATION | | | |
|---|---|---------------|---|
| <p>Aboriginal Interests, defined as asserted or determined Aboriginal rights, including title, and treaty rights, are known to overlap or lie in the vicinity of the Project corridor. Potential adverse effects on the exercise of Aboriginal Interests as a result of Project construction and operation have been identified.</p> <p>Mitigation measures to address potential Project-related effects on intermediate components (ICs) and valued components (VCs) associated with the exercise of Aboriginal Interests are expected to be effective. With the application of mitigation, potential effects on the exercise of Aboriginal Interests are predicted to be negligible except in specific cases during Project construction and operation. To address potential effects during Project construction and operation, the development of an Archaeological and Heritage Resources Management Plan is proposed.</p> <p>In addition to mitigation measures proposed to address potential effects on ICs and VCs, ongoing engagement between the Ministry and Schedule B Aboriginal Groups will be undertaken. Such engagement will take place during Application Review and, if the Project is approved, following the issuance of an Environmental Assessment Certificate (EAC). Engagement will involve consultation on management plans and monitoring programs, related to the exercise of Aboriginal Interests.</p> <p>Ongoing engagement is also proposed to address other matters of environmental, economic, social, heritage, and health concern raised Aboriginal Groups during the pre-Application period. With this ongoing engagement, residual effects on the exercise of Aboriginal Interests or other matters of concern as a result of the Project are not expected.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Capacity funding to facilitate participation in the Project review process | Penelakut Tribe received funding for the Pre-Application Phase. The Ministry will provide further funding for the Application Review Phase. | Addressed | Consultation regarding funding for the Application Review Phase |
| Appropriate use of information shared by Penelakut Tribe as it relates to confidentiality and dissemination | The Ministry understands and respects that certain information shared by Penelakut Tribe may be considered confidential. The Ministry is subject to the provisions of the Freedom of Information and Protection of Privacy Act. However, subject to the requirements of applicable laws, the Ministry will respect Penelakut Tribe requests to keep information confidential. | Addressed | Appropriate use of confidential information |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |

| Funding for Traditional Use Study | The Ministry signed funding agreements with Penelakut Tribe which provided funding for a Traditional Use Study. | Addressed | None |

ABORIGINAL PARTICIPATION AND PROJECT RELATED OPPORTUNITIES

The Ministry is actively exploring opportunities to provide benefits, economic and non-economic, to Aboriginal Groups that are directly affected by the Project. Opportunities include employment, training, and contracting as well as participation in environmental enhancement and other components of the Project.

Prior to the Pre-Application Phase of the Project, the Ministry worked with Schedule B Aboriginal Groups to determine appropriate tools to support consultation. Consultation activities were based on the specific needs and preferences of these Aboriginal Groups and the Consultation Plan included individualized plans that were co-developed and reviewed.

The Project’s Aboriginal Consultation Plan has been developed in consultation with Schedule B Aboriginal Groups, in order to meet the Aboriginal consultation requirements as delegated by EAO and to maintain and, where possible, enhance positive working relationships between the Ministry and the respective Aboriginal Groups.

The objectives and requirements of the Aboriginal Consultation Plan are to:

- Provide relevant Project-related information in a timely and effective manner that supports an understanding of the nature of the Project and its potential adverse effects on Aboriginal Interests
- Plan and implement mutually acceptable consultation activities that support effective participation of Aboriginal communities in the EA as well as related regulatory and permitting processes
- Establish and maintain dialogue throughout the EA as a means of providing opportunities to respond to outstanding concerns
- Provide opportunities for Aboriginal Groups to share views of the Project with the Ministry and EAO within reasonable timeframes
- Provide opportunities for Aboriginal Groups to identify potential adverse effects of the proposed Project on Aboriginal Interests, including cumulative effects and, to the extent appropriate, develop ways to mitigate or otherwise accommodate potential adverse effects
- Involve Aboriginal Groups, where possible, in relevant studies including, but not limited to, archaeological fieldwork.
- Incorporate community and traditional knowledge in Project components
- Document and report to EAO on the Ministry’s Aboriginal consultation program at times specified by EAO.

| Importance of Fraser Richmond Lands/Cowichan Village site to Cowichan Nation Alliance, particularly Penelakut Tribe, and the importance of considering future land recovery in land use and Project planning | Noted | Noted | None |
| City of Richmond’s land use planning process does not consider the Cowichan Nation Alliance’s potential future reclamation of the Fraser Richmond Lands - City of Richmond is working with the Ministry, but not with the Penelakut Tribe with respect to land use planning | Noted. Penelakut Tribe concerns have been referred to the City of Richmond | Addressed | None |
| Adequate training time to take full advantage of potential future Project work activities | The Ministry is committed to working with Penelakut Tribe to identify potential opportunities to benefit from the Project. Ministry acknowledges that Aboriginal Groups want to prepare their membership for employment opportunities and will work with Penelakut Tribe to identify ways to support community preparedness. | Ongoing | The Ministry will share information as it becomes available to support community preparedness and welcomes input from Aboriginal Groups on the type of information that would be useful. |

4.1 RIVER HYDRAULICS

The proposed bridge will have a clear-span, which eliminates potential changes to river hydraulics or river morphology resulting from the new structure. The Fraser River South Arm is dynamic with scour in the order of several metres during freshet and migrating sand dunes with heights of up to four metres. Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. Tunnel removal is expected to result in temporary bed lowering between the Tunnel and Lulu Island-Delta water main; however, no permanent effect on the Lulu Island-Delta watermain is expected.

Effects

A negligible effect to access to river locations for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of river locations has been determined.

Mitigation

Development of a mitigation plan to ensure protection to the Lulu-island-Delta water main.

Monitor the riverbed within 100 metres upstream and downstream of the watermain.

Stockpile appropriately-sized rock near the Project site, for priority scour protection repairs at the water main crossing.

Establish on-call contracts with a qualified registered professional and a qualified marine contractor prior to Tunnel removal, to ensure that scour protection repairs can be designed and implemented on short notice

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|--|
| <p>Change in flow rates after Tunnel removal</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects to river hydraulics and river morphology within the Fraser River South Arm.</p> <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. | <p>Potential for contaminants in the tunnel and how this may affect tunnel decommissioning.</p> | <p>The Ministry will consult with Fisheries and Oceans Canada and Port Metro Vancouver regarding Tunnel decommissioning, and will incorporate the requirements of these agencies in the planning and implementation of decommissioning activities.</p> <p>If potentially hazardous building materials are identified in the Tunnel, a detailed plan for removing and appropriately disposing of such material will be developed prior to initiating decommissioning activities. Any potentially hazardous material identified will be managed in accordance with applicable legislation, including the B.C. Hazardous Waste Regulation, B.C. Reg. 63/88, and the Workers' Compensation Board of B.C. Occupational Health and Safety Regulation, B.C. Reg. 296/97.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in 4.1.4 and 4.2.4</p> |

4.2 SEDIMENT AND WATER QUALITY

The proposed bridge will have a clear-span, which reduces potential effects to sediment and water quality within the Fraser River South Arm. During Tunnel decommissioning, a minor, temporary increase in turbidity, as compared with baseline conditions, is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.

Project activities undertaken in the upland ditch systems will follow Standards and Best Practices for Instream Works.

Effects

A negligible effect on quality of water used for cultural purposes has been determined.

A negligible effect on quality of experience tied to use of water for cultural purposes has been determined.

Mitigation

Avoid effects through Project design.

Incorporate a stormwater collection and distribution system (stormwater detention ponds and biofiltration swales) into bridge design that will convey and discharge stormwater runoff to appropriate upland infrastructure for proper treatment.

Develop Construction Environmental Management and Operational Environmental Management plans.

Control suspended sediment during Tunnel decommissioning. Employment of construction methods that minimize levels of Project-induced turbidity. Use spoil barges equipped with sediment containment system (filter cloth, concrete lock blocks, straw bales) to transport removed material off-site.

Control suspended sediment during Project construction in and adjacent to Deas and Green Sloughs. Use of sediment control measures such as turbidity curtains and de-watered cofferdams.

Monitor water quality during construction.

Use timing windows for undertaking in-stream works.

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology or sediment and water quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|---------------------------------|--|
| <p>Potential effects of run off and drainage</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciative change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected. Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.2.4</p> |
| <p>Effect of the Tunnel on dissolved oxygen content within the river.</p> | <p>The Ministry is following up with Penelakut Tribe to obtain further clarification regarding their concern regarding the effect of the Tunnel on dissolved oxygen content within the river.</p> | <p>Ongoing</p> | <p>Clarification regarding concern</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|--------------------------|---|
| Impact of potential pollutants and contaminants within the tunnel walls on the river if left in place. | The tunnel decommissioning is anticipated to involve the removal of the four in-river sections of the Tunnel. | Addressed | None |
| Improved ditches will result in less filtering of deleterious materials | Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Sediment and Water Quality is addressed in Section 4.2 of the Application. | Addressed in Application | Implementation of mitigation measures outlined in Section 4.2.4 |
| Use and disposal of dredged and other, material in the river as well as general concerns related to dredging of the Fraser River. | Dredging to deepen the river is not a component of this Project and the Ministry is unaware of any plans by others to dredge the river deeper. The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. This is outlined in Sections 1.1.7.2 (Construction), 4.1 (River Hydraulics) and 4.2 (Water Quality and Sediment) of the Application. | Addressed in Application | None |

4.4 FISH AND FISH HABITAT

The proposed bridge will have a clear span over the Fraser River South Arm and Deas Slough, avoiding or minimizing Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Given the disturbed nature of much of the Project alignment, re-vegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by improvements to local water quality; removal of non-native species; and replanting with species that provide habitat value for fish and wildlife.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

Mitigation

Avoid effects through Project design.

Apply best management and environmental management practices.

Develop Construction Environmental Management and Operational Environmental Management plans.

Use timing windows for undertaking in-stream works.

Erosion and sediment control.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term potential of physical injury or mortality to fish through crushing or entrainment during the construction period.

No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|--|
| <p>Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon</p> | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon and salmon to Penelakut Tribe. Potential Project-related effects on fish and fish habitat are presented in Section 4.4 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.4.4</p> |
| <p>Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon</p> | <p>Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources can be mitigated effectively by scheduling such activities during periods of low tide, when work can be completed under shall water conditions or in the dry, thereby minimizing potential effects. No Project-related residual or cumulative effects on underwater noise conditions are expected. Underwater Noise and Fish and Fish Habitat are addressed in Sections 4.3 and 4.4 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.3.4 and 4.4.4</p> |

4.6 MARINE MAMMALS

Marine mammals, specifically harbor seals and sea lions, are known to use marine areas within the Project alignment. Other species of conversation interest, including southern resident killer whales, do not occur in the Fraser River. Underwater noise during construction is the key area of focus for potential Project-related effects on marine mammals. Underwater noise in the Fraser River South Arm from existing sources currently exceeds thresholds for disturbance to marine mammals approximately 20% of the time. The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.

Effects

A negligible effect on the availability of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

Mitigation

Apply standard industry and best management practices to activities such as pile driving that have the potential to generate underwater noise to ensure sound thresholds for the protection of marine mammals are adhered to.
 Marine Mammal Management Plan to be incorporated into the Construction Environmental Management Plan
 Monitor underwater noise.

Cumulative Effects

No significant Project-related residual or cumulative effects on marine mammals are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Penelakut Tribe has not voiced any specific issues or concerns with respect to Marine Mammals. | | | |

4.7 VEGETATION

The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development.

Project components and activities will be primarily located within the existing Highway 99 right-of-way, where the vegetation consists mainly of grassy, mowed verges. Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary marsh that occur in the vicinity of the Project. No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.

Effects

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to best management and environmental, terrestrial vegetation and wildlife management practices. Apply best practices such as flagging of at-risk ecosystems to avoid encroachment during construction.

Offset and enhance habitat. Create comparable habitat within the Project alignment to offset unavoidable potential Project-related effect, limited to a small reduction in area of the cattail marsh that overlaps with Project components. Replant disturbed areas with native species.

Invasive species management plan will be included in the Construction Environmental Management Plan

Cumulative Effects

No significant Project-related residual or cumulative effects on vegetation are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|---------------------------------|--|
| <p>Invasive plant species and proposed plans to manage presence during construction</p> | <p>Mitigation and management of invasive species are presented in Section 4.7 of the Application. The Ministry will develop and implement an Invasive Species Management Plan as part of the Construction Environmental Management Plan.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.7.4</p> |
| <p>Culturally significant plants should be used in planting plans</p> | <p>Planting plans will be developed during later stages of Project planning and design. Opportunities for inclusion of culturally significant plants in in planting plans will be considered at that time. The Ministry will consult Aboriginal Groups on the development of these plans.</p> | <p>Addressed</p> | <p>The Ministry will develop planting plans with consultation from Aboriginal Groups</p> |

4.8 TERRESTRIAL WILDLIFE

The Highway 99 corridor is a highly developed area and terrestrial wildlife has generally adapted to this current condition. Terrestrial wildlife along Highway 99 consists primarily of raptors, riverine birds, and small mammals. Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge. No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.

Effects

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to terrestrial vegetation and wildlife management best practices such as spatial and temporal avoidance, pre-construction surveys and nest survey protocols, wildlife salvage and translocation, flagging and management of sensitive areas, and timing window restrictions.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term probability of barn swallow habitat loss during the construction period. The new bridge will provide new nesting opportunities for barn swallows.

There is a low, long-term probability of barn owl mortality.

No significant Project-related residual or cumulative effects on terrestrial wildlife are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|--|
| <p>Potential light and noise effects on wildlife and fish.</p> | <p>The Ministry understands that Penelakut Tribe is concerned with the potential effects of light and noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |
| <p>Potential effects of the bridge structure on species such as waterfowl and migratory birds.</p> | <p>The Ministry understands that Penelakut Tribe is concerned with the potential effects of the new bridge structure on species such as mammals, waterfowl, bats, eagles and migratory birds. Installation of flight deflectors such as hedgerows at appropriate locations along the highlight will mitigate potential Project-related increase in traffic collision risk. Terrestrial Wildlife in addressed in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |

4.9 AIR QUALITY

Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in.

Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include a 35% reduction in particulate matter emissions, as compared with a 14% reduction without the Project; a 47% reduction in volatile organic compound emissions, as compared with a 40% reduction without the Project; and no exceedances of the current most stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.

The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.

Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.

Effects

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

Mitigation

Minimize effects through Project design.

Implement recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.

Measure and monitor vehicle emissions and road dust during Project operation.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--------|---------------------------|--------|-------------------------|
|--------|---------------------------|--------|-------------------------|

| | | | |
|--|---|---------------------------------|--|
| <p>Potential effects to air quality, particularly as it relates to terrestrial wildlife.</p> | <p>The Ministry understands that Cowichan Tribes is concerned with the potential effects of air quality, particularly on terrestrial wildlife species. Projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in. Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in improvement in air quality. The new bridge will allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as the Tunnel portals, where they accumulate today. Effects on air quality during Project construction will be minimized through implementation of recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |
|--|---|---------------------------------|--|

4.10 ATMOSPHERIC NOISE

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the highway but do not exceed what is acceptable for residential, educational or institutional facilities.

Effects

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

Mitigation

Minimize effects through Project design.

Adhere to construction best practices and the Ministry's 2014 *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways*.

Develop and implement a Noise Management Plan.

Noise monitoring program.

Site specific schedules and activities.

Residual & Cumulative Effects

With the application of mitigation, no significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|---|
| <p>Increase in traffic and consequent increase in associated noise and vibration due to the increases capacity of the new bridge.</p> | <p>The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new Bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment, after mitigation, are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the Highway but do not exceed what is acceptable for residential, educational or institutional facilities. Atmospheric Noise is addressed in Section 4.10 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.10.4</p> |
| <p>Choice of building materials in relation to noise and vibration</p> | <p>The Ministry confirms that appropriate building materials will be used to mitigate noise and vibration. Mitigation in accordance with the Ministry’s 2014 Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways will be implemented, as warranted, at select locations to avoid or minimize potential Project-related increase in post-construction noise levels. Atmospheric Noise is addressed in Section 4.10 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.10.4</p> |

5.2 MARINE USE

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, and sorting and booming, as well as commercial, recreational and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place within the vicinity of the Project.

A clear span crossing of the Fraser River is proposed to avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span to improve navigation in and out of the slough.

Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.

Effects

During construction, a measureable effect on access to instream locations for traditional use has been determined.

During construction, a measurable effect on quality of experience tied to access of instream locations for traditional has been determined.

During operation, a negligible effect on access to instream locations for traditional use has been determined.

During construction, a negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Develop and implement a Marine Access Management Plan to ensure that important marine use activities can be reconciled with temporary constraints associated with Project construction.

Establish communications protocols to advise in-stream construction activities.

Ensure appropriate lighting and marking for safe navigation.

Establish navigation protection zones during construction to avoid or minimize impact on marine use.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|---|
| <p>Potential effects of construction during fishing season on fishing activities. Impacts of Tunnel decommissioning on Aboriginal fisheries, specifically as it relates to timing.</p> <p>“The proposed project has a direct impact on how we are able to use and navigate the areas surrounding the proposed project, and the impact of the project as it limits this ability needs to be considered in the Aboriginal Interests Assessment.”</p> <p>“Future exercise of our Aboriginal rights to fish (and also to harvest) including in-water and upland of the South arm of the Fraser should be considered when assessing project impacts of our interests.”</p> | <p>Potential interference with Penelakut Tribe fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> <p>The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4</p> |
| <p>Facilitation of increased shipping in the river</p> | <p>The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river.</p> | <p>Addressed</p> | <p>None</p> |

5.3 LAND USE

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta.

The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect regional growth trends or current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.

Once the new bridge becomes operational, recreational experience in its vicinity is expected to change due to improvements in local air quality, shoreline restoration of Deas Island, and re-vegetation of areas currently supporting highway infrastructure; improved connectivity across the Deas Island Regional Park resulting from removal of the Tunnel portals; and shading adjacent to the bridge, overhead noise, and changes in local viewsapes.

The Project will not result in changes to existing land use beyond small amounts of land, outside of the existing right-of-way, that area required for the Project.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Residual & Cumulative Effects

There is a low, short-term probability of disturbance to residential, commercial and industrial land use during construction.

There is a moderate , short-term probability of disturbance to recreational users near the new bridge during construction

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|-----------|---|
| Interest in surplus Agricultural Land Reserve (ALR) lands being provided to Penelakut Tribe for creation of a gas station or other businesses | As part of the Project, agricultural land will be protected as much as practical. Once the project is completed, there will be a determination of surplus lands, if any, and disposition will follow the appropriate process including consultation. | Addressed | Determination of surplus lands and consultation |

6.1 HERITAGE RESOURCES

The Project is located in an area where substantial historical development has occurred and the majority of the Project alignment is characterized as having low archaeological potential. No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

No to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

A measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Develop and implement a Heritage Resources Management Plan, which will include a chance find procedure, to avoid impacts to previously unknown heritage resources that may be encountered during Project construction and operation.

Undertake additional archaeological surveys.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on heritage resources are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Protection of archaeological and heritage resources, including intangible heritage sites and specific concern for any effects on the ǻǻqtinǻs/TI'uqtinus site and potential archaeological values at interchanges</p> | <p>Ministry acknowledges that protection of archaeological sites as well as intangible heritage sites are of utmost importance to Penelakut Tribe.</p> <p>All Aboriginal Groups have been provided with a comprehensive list of these sites, the Archaeological Overview Assessment, the Archaeological Impact, and Heritage Resources Overview Assessment.</p> <p>Appropriate measures will be taken to ensure the protection of archaeological and heritage resources as outlined in Section 6.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures as outlined in Section 6.1.4</p> |
| <p>Participation in archaeological fieldwork and review of archaeological draft reports</p> | <p>Penelakut Tribe participated in all archaeological field work to date and was provided the opportunity to review draft archaeological reports.</p> | <p>Addressed</p> | <p>Penelakut Tribe will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports.</p> |
| <p>Ethnographical content in reports does not accurately reflect Penelakut Tribe's historical presence within the Project area</p> | <p>The Ministry noted Penelakut Tribe's concern that ethnographical content in Project reports does not accurately reflect Penelakut Tribe's historical presence within the Project area. The Ministry continues to work with Penelakut Tribe to address this concern.</p> | <p>Ongoing</p> | <p>Ongoing consultation</p> |

7.0 HUMAN HEALTH

Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health. The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options. The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased active and public transportation, improved traffic safety, improvement connectivity and access, improved emergency response, and economic development opportunities.

Future Project-related consultation with Aboriginal groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.

Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations, and emergency response.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

A negligible effect on access to instream locations for traditional use has been determined.

7.0 HUMAN HEALTH

A negligible effect on quality of experience tied to access of instream locations for traditional has been determined.
 A negligible effect on access to upland locations for traditional use has been determined.
 A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation
 Implement proven mitigation measures, effectively used during construction of projects such as the South Fraser Perimeter Road and Port Mann / Highway 1 Improvement, to ensure that temporary increases in ambient noise levels and air emissions during construction do not result in health effects.
 Implementation of mitigation measures outlined in Fish and Fish Habitat, Marine Mammals, Vegetation, Terrestrial Wildlife, Air Quality, Atmospheric Noise, Marine Use and Land Use.

Residual & Cumulative Effects
 No significant Project-related residual or cumulative effects on human health are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---|-------------------------|
| Aboriginal health is not currently being considered in the assessment | Aboriginal health was considered in the assessment of potential Project-related effects on human health, including community and social factors. Human Health is addressed in Section 7.1 of the Application. | Addressed in Assessment and Application | None |
| Current conditions along the foreshore and in the Fraser River are not properly understood and have not been considered in the Human Health Assessment | Current conditions along the foreshore were considered in the assessment of potential Project-related effects on human health, including community and social factors. Human Health is addressed in Section 7.1 of the Application. | Addressed in Assessment and Application | None |

| 8.0 ACCIDENTS AND MALFUNCTIONS | | | |
|---|--|--------------------------|--|
| <p>Adherence to the practices and procedures contained in the Construction Environmental Management Plan will minimize the potential for accidents and malfunctions to occur.</p> <p>In general, replacement of the Tunnel with a new crossing and the proposed highway improvements are expected to lower the risk of accidents and malfunctions during highway operations and maintenance</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations | As outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan), an Emergency Response and Spill Contingency Plan will be developed. The Plan will outline how construction personnel will prevent, prepare for, respond to, and clean up spills. | Addressed in Application | Implementation of mitigation measures outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan) |
| Contaminants from automobile emission currently captured in Tunnel. New Bridge will send emissions directly into the air and Fraser River and settle on the foreshore | Automobile emissions are currently released from the Tunnel through a series of vents. Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in. Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. The new bridge will allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as the Tunnel portals, where they accumulate today. | Addressed | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|-----------|-------------------------|
| | Effects on air quality during Project construction will be minimized through implementation of recognized mitigation measures and best management practices that have proven to be effective on other transportation projects. | | |
| New Bridge could “unleash pent-up demand” and create even more congestion | The Project has been designed to address issues related to current and future traffic safety, congestion and reliability, and to help achieve regional mode share targets by facilitating travel across the Fraser River by transit, HOVs, cycling and walking. During operations, the Project will provide travel time savings for commuters or 25-35 minutes per day, improve safety with a forecast 35 percent reduction in collisions, and support provincial and regional strategies to encourage mode shift to transit and carpooling. As proposed, Project-related improvements, including tolling, will moderate traffic growth while effectively serving forecast demand at the crossing. | Addressed | None |

APPENDIX K

Semiahmoo First Nation

1.0 Introduction

This appendix provides a summary of the information presented in Part C Aboriginal Consultation (Part C) of the Application for an Environmental Assessment Certificate (the Application) regarding the assessment of effects on Aboriginal Interests. Aboriginal Interests are defined as asserted or determined Aboriginal rights, including title, or treaty rights. This appendix presents the information specific to Semiahmoo First Nation (Semiahmoo).

The organization of the information presented generally follows Part C and includes the following sections:

- Consultation;
- Community Profile;
- Existing Conditions;
- Potential Effects;
- Mitigation;
- Residual Effects; and
- Summary and Conclusion.

For more detailed information on the effects assessment on Aboriginal Interests related to Semiahmoo, refer to the following sections of Part C:

- Consultation with Semiahmoo (**Section 10.1.2.10**);
- Semiahmoo community profile (**Section 10.1.1.8**);
- Description of existing Semiahmoo Aboriginal Interests (**Section 10.1.3.2**);
- Assessment of potential effects of the Project on the exercise of Semiahmoo Aboriginal Interests (**Section 10.1.3.3**);
- Mitigation relating to potential effects on Aboriginal Interests (**Section 10.1.3.4**); and
- Residual effects on Semiahmoo Aboriginal Interests following application mitigation (**Section 10.1.3.5**).

A summary of Aboriginal Interests Assessment for Semiahmoo is also provided in **Section 10.1.3.8**.

The summary presented in this appendix also incorporated information found in the Semiahmoo Overview Table (**Appendix K2**), which provides detailed information regarding:

- Semiahmoo's issues and concerns identified to date;
- Identification of potential effects on VCs and ICs that relate to the assessment of effects on Semiahmoo's Aboriginal Interests;
- The Ministry's response to specific issues and concerns raised by Semiahmoo;
- The status of these issues and concerns; and
- Next steps required to address outstanding issues and concerns.

2.0 Consultation

This section provides information regarding the consultation activities that the EAO and Ministry carried out prior to submission of the Application.

2.1 EAO-led Consultation Activities

2.1.1 Capacity Funding

When a provincial agency is a proponent of a project going through a provincial EA under the British Columbia *Environmental Assessment Act* (BCEAA), that agency provides funding to Aboriginal Groups to support their involvement in pre-Application and Application review phases in place of EAO providing such funding. The Ministry's provision of capacity funding is discussed in the following section, Proponent-led Consultation Activities.

2.1.2 Participation in Working Group

EAO invited Semiahmoo and all other Aboriginal groups identified in Schedule B of the Section 11 Order to participate as members of a Working Group.

During the Pre-Application stage, Semiahmoo attended two EAO-led Working Group meetings where the Ministry presented information on the Project and the environmental assessment process and received and responded to comments on those presentations.

The first Working Group meeting, held January 2016, focused on the environmental assessment process, Project overview and update, Key Areas of Study, draft Application Information Requirements overview, and preliminary conclusions from study results.

The second working group meeting, held March 2016, focused on the environmental assessment process, list of materials available on the Project website, review of comments received on, and resulting changes to, the draft Application Information Requirements, and a description and rationale of the assessment areas. Working Group comments raised by Semiahmoo in relation to the draft Application Information Requirements resulted in Aboriginal groups being invited to participate in river-otter related fieldwork in April 2016. The objectives of this work were to document river otter presence or potential presence within the Regional Assessment Area, document and describe use of riparian and high use areas and identify potential Project-related effects.

Semiahmoo also participated in the completeness review of the Application for an Environmental Assessment Certificate (Application) that considered whether the Application included information requirements set out in the Application Information Requirements.

It is assumed that Semiahmoo will continue as an active member of the Working Group through the environmental assessment process.

2.2 Proponent-led Consultation Activities

The Ministry began consultation with Semiahmoo in early 2013 in order to identify the nature and scope of Semiahmoo's Aboriginal Interests and how they might be impacted by the Project. Following is a summary of consultation activities led by the Ministry with Semiahmoo. A more detailed discussion is provided under the Semiahmoo section in **Section 10.1.2.10 Overview of consultation with each Schedule B Aboriginal Group**. The following sections represent the main activities undertaken in support of Proponent-led consultation and include the following:

- Provision of capacity funding;
- Traditional use, traditional knowledge and other studies;
- Examples of Consultation Phase Activities; and
- Concerns Identified to Date.

2.2.1 Capacity Funding

The Ministry entered into a Participation Funding Agreement, including the Initial Consultation and Pre-Application phases for consultation, with Semiahmoo. The Ministry has been working with Semiahmoo regarding their needs for capacity funding to facilitate their participation in the Application Review Phase. Consultation activities that are anticipated to be undertaken during the Application Review Phase that will be supported by capacity funding include participation in technical reviews and analyses, involvement in ongoing consultation activities, and presentation of key information regarding their respective Aboriginal Interests.

2.2.2 Traditional Use, Traditional Knowledge & Other Studies

During Initial Consultation meetings, Semiahmoo identified the need for capacity funding to support Semiahmoo's involvement in Project consultation activities, review of EA-related documents and participation in the Pre-Application phase of the EA process. Semiahmoo also identified the need for funding for a Semiahmoo First Nation traditional use study and the Ministry and Semiahmoo worked together to finalize a funding agreement. The agreement specifies the activities covered under the agreement and Project/EA-related documents for Semiahmoo's review and comment. Semiahmoo did not submit a traditional use study.

2.2.3 Examples of Consultation Activities

A number of consultation activities were undertaken with Semiahmoo during both the Initial Consultation Phase and the Pre-Application Consultation Phase as follows:

Initial Consultation Phase Activities - The Ministry recognized the importance and value of early engagement with Schedule B Aboriginal Groups and undertook an Initial Consultation Phase prior to the Pre-Application Phase. The Initial Consultation Phase concluded in December 16, 2015 with submission of the Project Description and Key Areas of Study document. The focus of the Initial Consultation Phase was collection of baseline information and sharing of draft EA-related documents (i.e. Project Description and Key Areas of Study, draft Application Information Requirements (AIR)). The main consultation activities the Ministry undertook with Semiahmoo included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Semiahmoo;
- Funding for Semiahmoo's participation in Project consultation activities and EA process;
- Semiahmoo participation in field studies;
- Site visit;
- Review of draft EA documents such as the Project Description and Key Areas of Study, Heritage Resources Overview Assessment/Archaeological Overview Assessment, Heritage Resources Assessment, draft AIR, and Aboriginal Consultation Plan;
- Meetings with Semiahmoo leadership, staff, consultants, elders and membership; and
- Response and follow up with Semiahmoo regarding the identification and resolution of issues.

Pre-Application Consultation Phase Activities - The Pre-Application Consultation Phase began with the filing of the Project Description and Key Areas of Study on December 16, 2015 and concluded with the submission of the Application. This phase included the issuance of the Section 11 Order, AIR development and collection of baseline information. The main consultation activities the Ministry undertook with Semiahmoo included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Semiahmoo;
- Funding for Semiahmoo's participation in Project consultation activities and EA process;
- Meetings with Semiahmoo leadership, staff, consultants, elders and membership;
- Semiahmoo participation in fieldwork;
- Semiahmoo participation in the EA Working Group;
- Review of draft EA documents such as the AIR, Aboriginal Consultation Plan, and Aboriginal Consultation Reports;
- Review of draft Part C content for the Application; and
- Response and follow up with Semiahmoo regarding the identification and resolution of issues.

2.2.4 Concerns Identified to Date

As outlined above, Semiahmoo’s concerns, identified through consultation undertaken to-date, are presented in **Appendix K2 Semiahmoo Indian Band Overview Table**. The Ministry’s response to Semiahmoo’s key concerns regarding potential impacts on Semiahmoo’s Aboriginal Interests are outlined below:

Table 1 Concerns Identified to Date

| Concerns Identified to Date | Response |
|--|---|
| Protection of Semiahmoo First Nation’s rights to harvest within the Project area. | Semiahmoo’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife, residual effects on the exercise of Aboriginal Interests by Semiahmoo as a result of the Project are not expected. |
| Aboriginal participation and Project-related opportunities <ul style="list-style-type: none"> • Potential employment, training, contracting and economic development opportunities • Community preparedness • Cultural recognition and naming • Revenue from tolling | The Ministry is committed to working with Semiahmoo to identify potential employment, training, contracting and economic development opportunities and to identify ways to support community preparedness. The Ministry is exploring opportunities for cultural recognition and naming and will work with Semiahmoo on these opportunities. Revenue from tolling is only used to defray the costs of designing, constructing, operating and maintaining highways. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application. |

| Concerns Identified to Date | Response |
|---|---|
| <p>Environmental Assessment (EA):</p> <ul style="list-style-type: none"> • Adequacy of methodology to address social and cultural effects • Process and associated timelines | <p>The Ministry acknowledges the importance of Semiahmoo’s involvement in the environmental assessment process and is committed to funding Semiahmoo’s participation in the Initiation Consultation and Application Review phases.</p> <p>Semiahmoo’s concerns related to Environmental Assessment including the adequacy of methodology to address social and cultural effects and process and associated timeline are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> |
| <p>Ministry’s approach to procurement for the Project will not result in meaningful benefits to Aboriginal Groups</p> | <p>The Ministry is confident that the Project’s procurement process will effectively allow for benefits to be provided to Aboriginal Groups.</p> |
| <p>Effects to fish and fish habitat</p> <ul style="list-style-type: none"> • Importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon • Potential effects of pile driving, blasting and underwater noise generated by Tunnel decommissioning and other construction activities | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon, salmon to Semiahmoo and is committed to avoiding or mitigating any potential effects.</p> <p>The Ministry designed a clear span bridge over the Fraser River South Arm and Deas Slough to avoid or minimize Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Semiahmoo’s Fisheries Department continues to be very helpful in the review of Green Slough concepts.</p> <p>As outlined in Section 4.3 (Underwater Noise), sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Underwater noise from these sources will be effectively mitigated by scheduling activities during period of low tide, when work can be completed under shallow water conditions or in the dry.</p> |

| Concerns Identified to Date | Response |
|---|--|
| <p>Social effects of the Project on Semiahmoo’s ability to transfer knowledge, language and participate in socio-cultural practices</p> | <p>Social effects of the Project on Semiahmoo’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of Part C of the Application.</p> |
| <p>Potential effects of construction during fishing season on fishing activities. Effects of construction and decommissioning-related barging activities on Semiahmoo fishing.</p> | <p>Semiahmoo’s access to the Fraser River and the potential to displace fishing vessels (access to river locations for traditional use as a result of changes to physical characteristics of these locations) is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8). Mitigation measures are outlined in Section 5.2.4 (Marine Use Mitigation Measures) of the Application.</p> |
| <p>Cumulative effects:</p> <ul style="list-style-type: none"> • Consideration of cumulative effects on Aboriginal rights • Assessment of cumulative effects in regards to the inclusion of other reasonably foreseeable projects and activities • Absence of comprehensive study on cumulative effects on the Fraser River | <p>The Application includes historical context relating to changes in use over time by Semiahmoo and other Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by Semiahmoo or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests.</p> <p>While the Ministry acknowledges that Semiahmoo is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project. The Ministry understands that Semiahmoo is discussing this request with other provincial and federal ministries and agencies.</p> |

| Concerns Identified to Date | Response |
|--|---|
| Potential effects on Fraser River flow rates and sediment transport and disposition in Boundary and Semiahmoo Bays after Tunnel removal. | Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Flow rates are discussed in Section 4.1 (River Hydraulics). |
| Potential effects of run off and drainage | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation.</p> <p>During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.</p> <p>Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will ensure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected.</p> <p>Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> |

3.0 Community Profile – Semiahmoo First Nation

Semiahmoo First Nation is governed by a chief and council with two-year terms under an *Indian Act* electoral system. The current term for the three-member council expires in December 2016.

Semiahmoo First Nation has one reserve, fronting Semiahmoo Bay (part of Boundary Bay) at the Canada-United States border, about 1 km southeast of White Rock. The reserve, covering 129.10 ha, is home to 51 of the nation's 97 registered members. Originally 158.64 ha, portions of the reserve have been successively taken up for public purposes, including for the construction of Highway 99 in 1962. While the Highway 99 corridor runs adjacent to the eastern border of the reserve, the Project area does not include that section of the corridor.

Semiahmoo traditional territory has been previously represented as centred on Boundary Bay, taking in eastern portions of the Point Roberts peninsula, Mud Bay, and the lands and waters in and around the Serpentine, Nicomekl, and Campbell rivers. Semiahmoo First Nation has recently presented a more extensive territory that, still centred on Boundary Bay, takes in the Lower Fraser River and adjacent lands downstream of the confluence with the Sumas River, all of the Gulf Islands south of Gabriola Island, the San Juan Islands, most of Bellingham Bay, and the Nooksack River. The boundaries of this territory largely take in almost the entire Project area.

3.1 Semiahmoo Aboriginal Interests: Existing Conditions

This section provides a high level of summary of past, present, and desired future use of the proposed Project area and surroundings for traditional purposes are or may be connected with the exercise of Semiahmoo's Aboriginal Interests. A more detailed discussion, including sources used, is provided under Semiahmoo in **Section 10.1.3.2 Existing Conditions**.

3.1.1 General

- Semiahmoo has Aboriginal Interests that are known to overlap or lie in the vicinity of the Project corridor, which includes a portion of the South Arm of the Fraser River.
- The current exercise of Aboriginal Interests by Semiahmoo at locations or in relation to resources that may be potentially affected by Project construction or operation is relatively low.
- Semiahmoo has identified past and ongoing effects that have altered and reduced use over time, constraining the current exercise of their Aboriginal Interests.

3.1.2 Fishing

- Semiahmoo has reported that they once fished for salmon, sturgeon, halibut, eulachon, herring, smelts, sea mammals (including hair seals, sea lions, and porpoises), and a range of beach foods.
- Important salmon fishing areas have been previously identified as including but not limited to Cannery Point on the southeast tip of the Point Roberts Peninsula and the Nicomekl and Little Campbell rivers that feed into Boundary Bay, where sturgeon was also taken.
- Semiahmoo said that they practiced their fishing rights in the Fraser River in the summer season at *Tl'ektines*, in the vicinity of the north end of the George Massey Tunnel. They have previously “acknowledged that Cowichan Tribes fished in the South Arm of the Fraser River and that access to this area was gained by the Semiahmoo First Nation via a series of marriage ties between Semiahmoo First Nation and Cowichan Tribes”.
- Semiahmoo First Nation has also said that they have access rights to the Salmon River and Kanaka Creek, which both join the Fraser River in the vicinity of MacMillan Island, near Fort Langley.
- Shellfish were also important to the Semiahmoo, and Boundary Bay has been characterized as formerly one of the most productive shellfish harvesting locations on the Pacific coast. This feature is said to have made it a key shellfish harvesting location for the Semiahmoo and other First Nations, who reportedly shared the area for this purpose.
- Semiahmoo reports that the focus of their sea mammal harvesting was on seals. They have said that seals travelled as far up the Fraser River as Harrison Lake in pursuit of salmon.
- Semiahmoo reports that they are not currently engaged in commercial salmon fisheries.
- Sturgeon and eulachon once served as an important substitute for other fisheries; however, current conservation measures prohibit retention of these species.
- Semiahmoo reports that currently they are not participating in the commercial crab fishery, but has conveyed an interest in becoming involved in commercial shellfish harvesting, particularly of geoduck, and in developing aquaculture and commercial harvesting of sea cucumber .

3.1.3 Hunting/Trapping

- Semiahmoo hunting has been previously reported as concentrated in and around lands to the east of Boundary Bay, on both the Canadian and American sides of the border.
- Beaver is also said to have been taken at the heads of the Serpentine and Nicomekl rivers (present-day Surrey and Langley), as well as bear.

- Mountain goat was reportedly accessed outside of Semiahmoo territory, specifically on the north side of the Fraser River, via a trail along Kanaka Creek.
- Cranes, ducks, geese, swans, and other migratory birds were reportedly harvested for food, while ducks and duck down were also utilized for ceremonial and textile purposes.

3.1.4 Gathering

- Semiahmoo reports harvesting camas in the past on Waldron Island in Washington State, which is across Boundary Pass from South Pender and Saturna islands.
- Aquatic plants were also harvested, including bulrushes, tule rushes, and grasses. These were reportedly used extensively in the manufacture of mats, which were in turn used for a variety of purposes.
- Semiahmoo reportedly practiced selective burning to boost berry plant growth, which also had the effect of increasing the availability of deer.
- Blackberries, blueberries, dew berries, huckleberries, salmon berries, Saskatoon berries, and thimbleberries were important summer harvests for Semiahmoo; gooseberries, raspberries, and strawberries were also consumed, but were not as common.
- Semiahmoo First Nation has said cranberry harvesting provided seasonal employment for their members following non-Aboriginal settlement.
- Among other plants used traditionally by Semiahmoo has identified as devil's club, rose hip, stinging nettle, and the wood, bark, or roots of various tree species (e.g., cedar, cherry, fir, spruce, willow, and yew), for a variety of purposes.
- The lower Fraser River, in the vicinity of Deas and Tilbury Islands, has previously been identified as an area where current plant harvesting by Semiahmoo may still occur.

3.1.5 Archaeology and Cultural Heritage Interests

- Semiahmoo has said that the use of lands and resources, access to which they report as now limited, has a spiritual and sacred element not readily separated from practical considerations.
- Legendary stories, which relay that people related to the first ancestors, who descended from the sky, were transformed by Khaals (i.e., a mythical leader) into physical and biological elements of the landscape, and who remain relatives of the Semiahmoo.
- The Semiahmoo considers themselves part of the landscape, of their territory, and this landscape serves as their sacred place, their history book, their storehouse of raw materials, as well as their training ground.

- Named places in the vicinity of the Project area previously reported by Semiahmoo include *SĆUOŦEN*, or Semiahmoo, as well as three sites on the eastern aspect of the Point Roberts Peninsula, fronting Boundary Bay, as follows from north to south:
 - *ŦESEWEL*;
 - *ŚAWOM*; and
 - *ĆEL,ŁTENEM* (also rendered Chelhtenem or Tsel-Ihtenem, at Cannery or Lily Point).
- *ĆEL,ŁTENEM* has been previously identified as a summer residence of the Semiahmoo, as well as an important reef-net location for sockeye, while another summer residence of the Semiahmoo, where clams were harvested, has been previously identified in the vicinity of *ŦESEWEL* and *ŚAWOM*.
- Another named place has also been previously identified along the main stem of the Fraser River upstream of the Port Mann Bridge, at *KITEY*, or Katzie.

3.1.6 Other Related Interests

- Semiahmoo has reported that their ability to pursue a traditional economy has been “severely limited” by urbanization and contamination of their food supply within their traditional territory. They are seeking to restore or maintain, within that territory, the conditions necessary to promote the exercise of ancestral uses in the future.

4.0 Potential Effects

This section provides a summary of the methodology used to identify potential adverse effects of the proposed Project on the exercise of Aboriginal Interests by Aboriginal Groups during Project construction and operation, followed by a summary of potential effects on Semiahmoo’s Aboriginal Interests, specifically. For a more detailed description of the methodology and a summary of the results, refer to **Section 10.1.3.3. Potential Effects**.

4.1 Methodology for Identification of Potential Effects

The first step in the effects assessment on Aboriginal interests was the identification of potential adverse effects on traditional use activities and related interests as a result of Project construction or operation. To evaluate these potential adverse effects, the findings of the following Valued Component (VC) chapters in Part B of the Application were considered, including identified mitigation measures, residual effects, cumulative effects and follow up strategies:

- **Section 4.4 Fish and Fish Habitat**
- **Section 4.6 Marine Mammals**
- **Section 4.7 Vegetation**

- **Section 4.8 Terrestrial Wildlife**
- **Section 5.2 Marine Use**
- **Section 5.3 Land Use**
- **Section 5.5 Visual Quality**
- **Section 6.1 Heritage Resources**
- **Section 7.1 Human Health**

The findings of the following Intermediate Component (IC) chapters were also considered in the assessment:

- **Section 4.1 River Hydraulics and River Morphology**
- **Section 4.2 Sediment and Water Quality**
- **Section 4.9 Air Quality**
- **Section 4.10 Atmospheric Noise**

The assessment of potential adverse effects of the Project on the exercise of Aboriginal Interests, including measures to address those effects, are presented in **Section 10.1.3.3** through **Section 10.1.3.5**, and largely applies the same methods used in Part B of the Application for the IC and VC assessments, as outlined Section 3.0 Assessment Methodology.

In addition to information from the VC and IC assessments that support the assessment of potential effects on Aboriginal Interests, information from a Health Impact Assessment (HIA) undertaken to support Project planning, including mitigation recommendations, has been integrated into the assessment of potential effects on Aboriginal Interests. The HIA for the Project can be found at <https://engage.gov.bc.ca/masseytunnel>. A summary of the key findings is provided in **Section 7.2 Health Impact Assessment**.

4.2 Selection of Indicators

Four parameters were chosen as indicators to understand and evaluate potential Project-related effects on the exercise of Aboriginal Interests. The rationale for their selection is presented in the following table.

Table 2 Indicators for the Aboriginal Interests Assessment

| Indicator | Rationale for Selection |
|---|---|
| Access to preferred locations for the exercise of Aboriginal Interests | Project components or activities could result in changes in access to or patterns of travel between traditional use locations on land or water |
| Availability of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in distribution or movement, relative abundance, or habitat area or composition of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in the real or perceived quality of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests | Project components or activities could result in: (1) direct sensory disturbance to traditional users (e.g., from noise, vibration); and/or (2) indirect changes to cultural practices, customs or traditions – i.e., cultural heritage or the expression and transfer of cultural values or ways of knowing (e.g., language, laws/governance, stories, spiritual beliefs) – tied to the cultural landscape or to the traditional use of specific traditional use locations or resources within that landscape. |

Potential adverse effects on the indicators noted above were analyzed in terms of the type and level of effect that Project components and activities may be expected to have on the exercise of Aboriginal Interests.

For the purposes of this assessment, no effect was understood to mean that no interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests would be expected. Where it was determined that an interaction, and potential effect, could occur, the following definitions were used to guide the characterization of the effect as negligible or measurable:

- Negligible – An interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests may occur, but modifications to the use of preferred options would not be expected.

- Measurable – Modifications to the exercise of Aboriginal Interests at preferred locations or in relation to preferred resources may be needed, and may be considered to be:
 - Minor (minimal or temporary modifications may be required to use preferred options),
 - Moderate (more frequent or longer term modifications may be required to use preferred options), or
 - Serious (permanent or indefinite modifications may be required potentially resulting in the loss of preferred options).

4.3 Identified Potential Effects

As noted above, the first step in evaluating potential adverse effects on Aboriginal Interests was a consideration of the findings for relevant Part B VCs and ICs, including identified mitigation measures, residual effects, cumulative effects and follow up strategies. The residual effects with the potential to have an adverse effect on Aboriginal Interests are then carried forward in the assessment. Using the four indicators noted in the previous section, the potential Project-related effects and level of effect predicted in relation to Semiahmoo's exercise of Aboriginal Interests remaining after Part B mitigation are as follows:

Table 3 Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|---|--------------|------------|------------|------------|----------------------------|
| | Negligible | Measurable | Negligible | Measurable | |
| River locations for traditional use as a result of changes to physical characteristics of these locations | ✓ | | ✓ | | |
| Instream locations for traditional use | ✓ | | ✓ | | |
| Upland locations for traditional use | ✓ | | ✓ | | |

Table 4 Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests

4.4 Potential Project-Related Effects on Semiahmoo's Aboriginal Interests

Using the methodology presented in **Section 10.1.3.3 Potential Effects**, Table 7 provides the potential incremental Project-related effects, following mitigation of Project-related effects on Part B VCs and ICs as described in Part B, related to Semiahmoo's Aboriginal Interests as summarized in Existing Conditions were identified for Project Construction and Operation. A discussion of potential Project-related effects on fishing, hunting/trapping, gathering and archaeology and cultural heritage follows the table.

Table 7 Summary of Potential Project-Related Effects

| Indicator | Potential Project-Related Effect | Potentially-Affected Aboriginal Interests |
|--|---|--|
| Project Construction | | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |

4.5 Fishing

Semiahmoo has reported that they once fished for salmon, sturgeon, halibut, eulachon, herring, smelts, sea mammals (including hair seals, sea lions, and porpoises), and a range of beach foods. Semiahmoo said that they fished in the Fraser River in summer at *Tl'ektines*, in the vicinity of the north end of the George Massey Tunnel. Other important salmon fishing areas have been previously identified as including the southeast tip of the Point Roberts Peninsula and the Nicomekl and Little Campbell rivers that feed into Boundary Bay. Semiahmoo report that Boundary Bay was particularly productive for shellfish.

The proposed Project has the potential to affect fishing practices through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred fishing locations by Semiahmoo, as a result of changes in river hydraulics or morphology, are expected to be negligible before mitigation. Potential changes in access to instream locations for fishing by Semiahmoo during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to fishing locations by Semiahmoo from instream construction activities are expected to be negligible. While it is acknowledged that Semiahmoo has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Mitigation measures identified in the fish and fish habitat assessment to address Project-related effects on fish are expected to be effective at addressing potential effects on the availability of fishing resources preferred by Semiahmoo. Further, as residual effects on fish identified in the fish and fish habitat assessment are not anticipated to affect population integrity, potential residual effects as a result of Project construction activities, would not be expected to measurably affect the availability of preferred fish resources.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of fishing resources preferred by Semiahmoo; therefore, Potential Project-related effects on Semiahmoo fishing would be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when fishing are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** are expected to largely address a potential Project-related effect to the quality of experience while fishing. At preferred fishing locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Semiahmoo.

Section 5.5 Visual Quality predicts that residual effects to visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Semiahmoo is fishing. As this landscape has been previously modified, the potential Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Semiahmoo's Aboriginal Interests related to fishing are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.6 Hunting/Trapping

Semiahmoo hunting has been previously reported as concentrated in and around lands to the east of Boundary Bay, on both the Canadian and American sides of the border. Species harvested in proximity to the Project area include beaver, waterfowl and migratory birds.

The proposed Project has the potential to affect hunting and trapping through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred hunting and trapping locations by Semiahmoo as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for hunting and trapping by Semiahmoo during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to hunting and trapping locations by Semiahmoo from instream construction activities, are expected to be negligible. While it is acknowledged that Semiahmoo has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for hunting and trapping by Semiahmoo resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with hunting and trapping locations.

Mitigation measures identified in the marine mammal and terrestrial wildlife assessments are expected to be effective at addressing potential effects on the availability of hunting and trapping resources preferred by Semiahmoo. Therefore, Project-related effects on hunting and trapping related to potential changes in the availability of resources would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for hunting and trapping by Semiahmoo; therefore, Potential Project-related effects on Semiahmoo fishing would be expected to be negligible.

Project operation is not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when hunting and trapping are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** to address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while hunting and trapping. At preferred hunting and trapping locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Semiahmoo.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Semiahmoo is hunting and trapping. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Semiahmoo's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.7 Gathering

Semiahmoo report that the lower Fraser River, in the vicinity of Deas and Tilbury Islands, has previously been identified as an area where gathering may still occur. Semiahmoo report gathering various species of aquatic plants, berries, devil's club, rose hip, stinging nettle, and the wood, bark, or roots of various tree species. Semiahmoo reportedly practiced selective burning to boost berry plant growth.

The proposed Project has the potential to affect gathering through changes in access to preferred locations, changes in availability of preferred resources, changes in quality of preferred resources and changes in quality of experience when gathering.

Potential changes in access to preferred gathering locations by Semiahmoo as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for gathering by Semiahmoo during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to gathering locations by Semiahmoo from instream construction activities, are expected to be negligible. While it is acknowledged that Semiahmoo has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for gathering by Semiahmoo resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with gathering locations.

Mitigation measures identified in the vegetation assessment to address Project-related effects on terrestrial vegetation are expected to be effective at addressing potential effects on the availability of resources for the exercise of Aboriginal Interests related to gathering. Therefore, Project-related effects on gathering related to potential changes in the availability of vegetation would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for gathering by Semiahmoo; therefore, Potential Project-related effects on gathering related to potential changes in the quality of resources would therefore be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when gathering are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in Section 4.10 Atmospheric Noise address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while gathering. At preferred gathering locations that overlap or are in proximity to known noise-sensitive locations for which Project operation-related effects may not be fully mitigable, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Semiahmoo.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Semiahmoo is gathering. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Semiahmoo's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.8 Archaeology and Cultural Heritage Interests

Semiahmoo has said that the use of lands and resources has a spiritual and sacred element not readily separated from practical considerations. Legendary stories, which relay that people related to the first ancestors, who descended from the sky, were transformed by Khaals (i.e., a mythical leader) into physical and biological elements of the landscape, and remain relatives of the Semiahmoo. Semiahmoo report named places in the vicinity of the Project area.

The proposed Project has the potential to affect Semiahmoo's Aboriginal Interests related to archaeology and cultural heritage through changes in access to preferred locations and changes in quality of experience.

Potential changes in access to locations related to Semiahmoo's archaeological and cultural heritage interests as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations related to Semiahmoo's interests related to archaeology and cultural heritage during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to locations related to Semiahmoo's archaeological and cultural heritage interests from instream construction activities are expected to be negligible. While it is acknowledged that Semiahmoo has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations related to Semiahmoo's archaeological and cultural heritage interests resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and not expected to overlap with locations related to Semiahmoo's archaeological and cultural heritage interests.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** would also be expected to address the potential Project-related effect to the quality of experience while undertaking activities related to cultural heritage. At locations related to Semiahmoo's archaeological and cultural heritage interests that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Semiahmoo.

As reported in **Section 6.1 Heritage Resources**, no archaeological or historical sites were identified within the Project area during fieldwork; however, there may be other locations with intangible cultural value or meaning to Semiahmoo (e.g., spiritual or storied sites, named places) potentially affected by the Project. In addition, physical alterations to the landscape may affect archaeological or historical sites, and how this landscape is experienced culturally.

As a result, mitigation measures proposed in Part B are not expected to address a potential incremental and permanent Project-related effect tied to Semiahmoo's Aboriginal Interests related to archaeology and cultural heritage that may be associated with the introduction of a new prominent feature to the cultural landscape. As this landscape has been previously modified by anthropogenic changes, the potential incremental Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal, but permanently disruptive for Semiahmoo, who have identified a historical connection to, and continued or desired use of, sites or places that help define the cultural landscape in the Project area.

Additional mitigation to address this potential incremental effect that is not otherwise addressed in the Application is proposed in **Section 10.1.3.4** and summarized below under Mitigation.

5.0 Mitigation

This section provides a summary of mitigation measures identified to address potential Project-related effects on the exercise of Aboriginal Interests by Semiahmoo. For a more detailed discussion, refer to **Section 10.1.3.4 Mitigation**.

Mitigation measures identified for the relevant VCs and ICs in Part B of the Application were reviewed to assess their effectiveness at addressing potential Project-related effects on the exercise of Aboriginal Interests related to those VCs. Examples of mitigation that are proposed in the Application to address potential effects on VCs and ICs, with the potential to result in an effect on Aboriginal Interests, include:

- Avoiding fisheries sensitive timing windows during key Project activities.

- Developing a Marine Access Management Plan to ensure marine use activities, including those supporting Aboriginal Interests, can continue during Project construction.
- Scheduling activities with the potential to generate underwater noise to avoid potential effects on marine mammals.
- Development and implementation of a Terrestrial Vegetation and Wildlife Management Plan with measures to minimize disturbance and loss of vegetation, prevent soil compaction, and minimize clearing in order to minimize effects on vegetation.

These measures are expected to be largely effective at avoiding, reducing, or otherwise managing potential Project-related effects on the exercise of Aboriginal Interests during Project construction and operation.

Recognizing some measurable effects on Semiahmoo's Aboriginal Interests could remain following the application of mitigation to address potential effects on the relevant VCs and ICs in Part B, the following additional measures have been identified to address such effects:

- Ongoing consultation with Semiahmoo regarding proposed measures, management plans, and monitoring programs related to intermediate components and valued components assessments; and
- Development of a Cultural Heritage Management Plan.

6.0 Residual Effects

With the implementation of mitigation measures identified in **Section 10.1.3.4** and summarized above, residual adverse effects of the proposed Project on the exercise of Aboriginal Interests are expected to be negligible (i.e., not measurable or detectable), and are not further assessed.

7.0 Summary and Conclusion

Part C of the Application builds on consultation undertaken to date to understand Semiahmoo's Aboriginal Interests and provides for an assessment of potential Project-related effects of the Project on Aboriginal Interests.

The Ministry began consultations with Semiahmoo prior to the submission of the Project Description, which is the end of the Initial Consultation Phase. Both EAO and the Ministry consulted with Semiahmoo during the Pre-Application Phase, which concluded with the submission of the Application. The main concerns expressed by Semiahmoo during consultations include:

- EAO process;

- Protection of Semiahmoo First Nation’s rights to harvest within the Project area;
- Semiahmoo First Nation’s access to the Fraser River and the potential to displace fishing vessels;
- Potential interference with Aboriginal fisheries during decommissioning of the Tunnel and the importance of working closely with communities to ensure negative effects are avoided;
- Social and cultural effects of the Project such as Semiahmoo First Nation’s knowledge transmission, language loss, dependency and social interaction;
- Potential effects from the Project on shellfish in Boundary Bay and on Semiamoo’s plans related to aquaculture;
- Capacity funding to facilitate participation in the EA process;
- Opportunities for cultural recognition and naming;
- Assessment of cumulative effects ;
- Potential increase in vessel traffic on the Fraser River as a result of decommissioning the Tunnel;
- Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations;
- Protection of archaeological, heritage, and cultural resources, including intangible heritage sites;
- Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon;
- Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon;
- Potential effects on wildlife;
- Traffic;
- Invasive plant species;
- Use of culturally significant plants in planting plans; and
- Potential effects of runoff and drainage.

Based on information provided by Semiahmoo and other publicly-available sources, the Ministry developed a summary of past, present and desired future use of the proposed Project area and its surroundings for the purposes of fishing, hunting/trapping, gathering, archaeology and cultural heritage interests and other related interests. This summary indicates that Semiahmoo has, does and intends to continue to use the Fraser River for cultural purposes.

Relying first on the results of the effects assessments for related VCs and ICs in Part B, the assessment of potential effects of Semiahmoo's Aboriginal Interests considered four indicators:

1. Access to preferred locations for the exercise of Aboriginal Interests;
2. Availability of preferred resources for the exercise of Aboriginal Interests;
3. Quality of preferred resources for the exercise of Aboriginal Interests; and
4. Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests.

As reviewed in **Section 10.1.3.3** and **Section 10.1.3.4**, the mitigation measures, management plans, and monitoring programs identified in Part B of the Application for ICs or VCs linked to the exercise of Aboriginal Interests are expected to be largely effective at addressing the incremental Project-related effects noted above on the exercise of Aboriginal Interests by Semiahmoo First Nation, except in the following potentially measurable cases:

- Project construction:
 - Potential temporary direct (minor) effect on quality of experience related to construction-related noise and a potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance
- Project operation:
 - Potential permanent direct (minor) effect on quality of experience related to traffic noise and a potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses
 - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses.

The following additional measures have been identified to address the above-noted effects:

- Ongoing consultation with Semiahmoo regarding proposed measures, management plans, and monitoring programs related to VC and IC assessments; and
- Development of a Cultural Heritage Management Plan.

With the implementation of mitigation proposed to address potential effects on VCs and ICs, as well as additional mitigation proposed to address potential residual effects on Aboriginal Interests, no effects on the exercise of Aboriginal Interests by Semiahmoo, as a result of the Project, are expected.

ENVIRONMENTAL ASSESSMENT PROCESS

An environmental assessment of the Project is required under the B.C. *Environmental Assessment Act* (B.C. *EAA*), S.B.C. 2002, c. 43, and permits to construct and operate can only be received once the environmental assessment process is complete and an Environmental Assessment Certificate (EAC) has been issued. If the Project is approved, an EAC will be awarded to and held by the Ministry. The Reviewable Projects Regulation B.C. Reg. 370/2002 under the B.C. *EAA* sets out the criteria for reviewable projects.

On December 16, 2015, the B.C. Environmental Assessment Office (EAO) issued a Section 10(1)(c) Order confirming that the Project is a reviewable project pursuant to the B.C. *EAA*, and that it requires an EAC.

The Project as proposed is not subject to review under the *Canadian Environmental Assessment Act, 2012*, S.C. 2012, c. 19, s. 52, since it does not meet the definition of a physical activity under the Schedule of Physical Activities in the Regulations Designating Physical Activities SOR/2012-147.

EAO is a neutral agency that manages the review of proposed major projects in British Columbia, as required by the *Environmental Assessment Act*.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------------|-------------------------|
| Social and cultural effects and the adequacy of EA methodology | <p>Concerns related to the adequacy of Environmental Assessment are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> <p>Social and cultural effects of the project are considered in Part C of the Environmental Assessment Application (Application). Where Aboriginal Groups values and perspectives have been provided to the Proponent regarding environmental, economic, social, heritage or health valued components (VCs), they have been incorporated, where applicable into the Part B assessment of those VCs.</p> | Referred to EAO | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------------|--------------------------------|
| Concern with the effectiveness of the EAO-led process to address Semiahmoo First Nation's concerns | Concerns relating to the effectiveness of the Environmental Assessment Process have been referred to EAO. | Referred to EAO | None |
| EA Studies are not meaningful and, instead, are check boxes | Comment noted. The Ministry does not share Semiahmoo First Nation's view of the value of EA studies and welcomes further discussion regarding this concern. | Noted | Further discussion |

ABORIGINAL INTERESTS

There are potential Project related impacts to Semiahmoo's title, Rights and culture. Potential effects and the level of effect predicted include:

1. Access to preferred locations for the exercise of Aboriginal Interests (access to river locations for traditional use as a result of changes to physical characteristics of these locations).
2. Availability of preferred resources for the exercise of Aboriginal Interests (availability of fish, marine mammal, vegetation and terrestrial wildlife resources for Traditional Use).
3. Quality of preferred resources for the exercise of Aboriginal Interests (quality of water used for cultural purposes, quality of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use).
4. Quality of experience of exercising, or tied to the exercise, of Aboriginal Interests (quality of experience tied to the traditional use of river locations as a result of changes to the physical characteristics of the location; quality of experience tied to access of instream and upland areas locations for traditional use; quality of experience tied to use of water for traditional purposes; quality of experience tied to the traditional use of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use; and quality of experience while engaged in or tied to traditional use as a result of changes in air quality, noise, ground-borne vibration and to the cultural landscape).

Measureable Effects

Access for traditional use

- Cultural landscape

Quality of experience while engaged in or tied to traditional use

- cultural landscape

No, Negligible or Moderate Effects

Quality of experience while engaged in or tied to traditional use

- Noise

Negligible Effects

Access for traditional use

- Instream locations
- River locations
- Upland locations

ABORIGINAL INTERESTS

Quality for Traditional Use

- Water
- Fish resources
- Marine mammal resources
- Vegetation resources

Quality of experience while engaged in or tied to traditional use

- Fish resources
- Instream locations (during construction)
- Marine mammal resources
- River locations
- Terrestrial wildlife resources
- Upland locations
- Water
- Vegetation resources

Availability for Traditional Use

- fish resources
- Marine mammal resources
- Terrestrial wildlife resources
- Vegetation resources

No to Negligible Effects

Quality of experience while engaged in or tied to traditional use

- changes to the cultural landscape

No or Negligible Effects

Quality of experience while engaged in or tied to traditional use

- Air quality
- Ground-borne vibration

ABORIGINAL INTERESTS

High, Short-term Probability of Effect

- Disturbance to residential, commercial and industrial land uses
- Disturbance to recreational uses near the new bridge

Moderate, Long-term Probability of Effect

- Disturbance to visual quality

Low, Short-term Probability of Effect

- Barn swallow habitat loss (construction period)
- Physical injury or mortality to fish through crushing or entrainment (construction period)

Low, Long-term Probability of Effect

- Barn owl mortality

No Significant Residual or Cumulative Effects

- Air quality
- Fish and fish habitat
- Heritage resources
- Marine access
- Marine mammals
- River hydraulics and river morphology
- Sediment and water quality
- Terrestrial Wildlife
- Vegetation

The Ministry has developed mitigation measures to address these Potential effects. Residual effects on the exercise of Aboriginal Interests by Semiahmoo as a result of the Project are not expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|--|
| <p>Protection of Semiahmoo First Nation’s rights to harvest within the Project area</p> | <p>Semiahmoo’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures outlined in Table 10.3-1 and Section 10.1.3.4, residual effects on the exercise of Aboriginal Interests by Semiahmoo as a result of the Project are not expected.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife)</p> |
| <p>Semiahmoo’s access to the Fraser River and the potential to displace fishing vessels. Potential interference with Aboriginal fisheries during decommissioning of the Tunnel and the importance of working closely with communities to ensure negative effects are avoided</p> | <p>Semiahmoo’s access to the Fraser River and the potential to displace fishing vessels (access to river locations for traditional use as a result of changes to physical characteristics of these locations) is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined. A negligible effect on access to instream locations for traditional use and a negligible effect to upland locations for traditional use has been determined.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation measures outlined in Section 5.2.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|---|
| <p>Social effects of the Project such as Semiahmoo First Nation’s knowledge transmission, language loss, dependency and social interaction</p> | <p>Social effects of the Project on Semiahmoo’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3.8 and Section 10.3 of Part C of the Application.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in all Sections of the Application</p> |
| <p>Capacity funding to facilitate participation in the Project review process.</p> | <p>Semiahmoo received funding for the Pre-Application Phase. The Ministry will provide further funding for the Application Review Phase.</p> | <p>Addressed</p> | <p>Consultation regarding funding for the Application Review Phase</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|------------------|-------------------------|
| <p>Revenue sharing opportunities from tolling</p> | <p>Revenue from tolling is only used to defray the costs of designing, constructing, operating and maintaining highways. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application.</p> | | |
| <p>Cumulative effects:</p> <ul style="list-style-type: none"> • Consideration of cumulative effects on Aboriginal rights. • Assessment of cumulative effects in regards to the inclusion of other reasonably foreseeable projects and activities. • Absence of a comprehensive study of cumulative effects on the Fraser River | <p>The Application will include historical context as outlined relating to changes in use over time by Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by First Nations or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests.</p> <p>The Ministry’s cumulative effects assessment looked at potential incremental environmental effects of construction and operation of the Project in conjunction with other present and reasonably foreseeable projects that could interact with the potential effects of this Project. The process and methodology used to conduct the cumulative effects assessment, including the identification of potential cumulative effects, identification of additional mitigation measures, and evaluation of any (residual) cumulative</p> | <p>Addressed</p> | <p>None</p> |

ABORIGINAL PARTICIPATION AND PROJECT-RELATED OPPORTUNITIES

The Ministry is actively exploring opportunities to provide benefits, economic and non-economic, to Aboriginal Groups that are directly affected by the Project. Opportunities include employment, training, and contracting as well as participation in environmental enhancement and other components of the Project.

Prior to the Pre-Application Phase of the Project, the Ministry worked with Schedule B Aboriginal Groups to determine appropriate tools to support consultation. Consultation activities were based on the specific needs and preferences of these Aboriginal Groups and the Consultation Plan included individualized plans that were co-developed and reviewed.

The Project's Aboriginal Consultation Plan has been developed in consultation with Schedule B Aboriginal Groups, in order to meet the Aboriginal consultation requirements as delegated by EAO and to maintain and, where possible, enhance positive working relationships between the Ministry and the respective Aboriginal Groups.

The objectives and requirements of the Aboriginal Consultation Plan are to:

- Provide relevant Project-related information in a timely and effective manner that supports an understanding of the nature of the Project and its potential adverse effects on Aboriginal Interests
- Plan and implement mutually acceptable consultation activities that support effective participation of Aboriginal communities in the EA as well as related regulatory and permitting processes
- Establish and maintain dialogue throughout the EA as a means of providing opportunities to respond to outstanding concerns
- Provide opportunities for Aboriginal Groups to share views of the Project with the Ministry and EAO within reasonable timeframes
- Provide opportunities for Aboriginal Groups to identify potential adverse effects of the proposed Project on Aboriginal Interests, including cumulative effects and, to the extent appropriate, develop ways to mitigate or otherwise accommodate potential adverse effects
- Involve Aboriginal Groups, where possible, in relevant studies including, but not limited to, archaeological fieldwork.
- Incorporate community and traditional knowledge in Project components

Document and report to EAO on the Ministry's Aboriginal consultation program at times specified by EAO.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |

4.1 RIVER HYDRAULICS

The proposed bridge will have a clear-span, which eliminates potential changes to river hydraulics or river morphology resulting from the new structure. The Fraser River South Arm is dynamic with scour in the order of several metres during freshet and migrating sand dunes with heights of up to four metres. Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. Tunnel removal is expected to result in temporary bed lowering between the Tunnel and Lulu Island-Delta water main; however, no permanent effect on the Lulu Island-Delta watermain is expected.

Effects

A negligible effect to access to river locations for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of river locations has been determined.

Mitigation

Monitor the riverbed within 100 metres upstream and downstream of the watermain.

Stockpile appropriately-sized rock near the Project site, for priority scour protection repairs at the water main crossing.

Establish on-call contracts with a qualified registered professional and a qualified marine contractor prior to Tunnel removal, to ensure that scour protection repairs can be designed and implemented on short notice

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|--|
| <p>Change in flow rates after Tunnel removal, inclusion of high flow period in River Hydraulic model. Effects of Tunnel removal on sediment transport.</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects to river hydraulics and river morphology within the Fraser River South Arm.</p> <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. River Hydraulics and River Morphology are addressed in Section 4.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4</p> |

4.2 SEDIMENT AND WATER QUALITY

The proposed bridge will have a clear-span, which reduces potential effects to sediment and water quality within the Fraser River South Arm. During Tunnel decommissioning, a minor, temporary increase in turbidity, as compared with baseline conditions, is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.

Effects

A negligible effect on quality of water used for cultural purposes has been determined.

A negligible effect on quality of experience tied to use of water for cultural purposes has been determined.

Mitigation

Avoid effects through Project design.

Incorporate a stormwater collection and distribution system (stormwater detention ponds and biofiltration swales) into bridge design that will convey and discharge stormwater runoff to appropriate upland infrastructure for proper treatment.

Develop Construction Environmental Management and Operational Environmental Management plans.

Control suspended sediment during Tunnel decommissioning. Employment of construction methods that minimize levels of Project-induced turbidity. Use spoil barges equipped with sediment containment system (filter cloth, concrete lock blocks, straw bales) to transport removed material off-site.

Control suspended sediment during Project construction in and adjacent to Deas and Green Sloughs. Use of sediment control measures such as turbidity curtains and de-watered cofferdams.

Monitor water quality during construction.

Use timing windows for undertaking in-stream works.

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology or sediment and water quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Potential effects of runoff and drainage</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will ensure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected.</p> <p>Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.2.4</p> |
| <p>Potential effects on Fraser River flow rates and sediment transport and disposition in Boundary and Semiahmoo Bays after Tunnel removal</p> | <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Flow rates are discussed in Section 4.1 (River Hydraulics).</p> <p>Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4 (River Hydraulics Mitigation Measures)</p> |

4.4 FISH AND FISH HABITAT

The proposed bridge will have a clear span over the Fraser River South Arm and Deas Slough, avoiding or minimizing Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Given the disturbed nature of much of the Project alignment, re-vegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by improvements to local water quality; removal of non-native species; and replanting with species that provide habitat value for fish and wildlife.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

Mitigation

Avoid effects through Project design.

Apply best management and environmental management practices.

Develop Construction Environmental Management and Operational Environmental Management plans.

Use timing windows for undertaking in-stream works.

Erosion and sediment control.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term probability of physical injury or mortality to fish through crushing or entrainment during the construction period.

No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|--------------------------|---|
| Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon | The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon and salmon to the Semiahmoo. Potential Project-related effects on fish and fish habitat are presented in Section 4.4 of the Application. | Addressed in Application | Implementation of mitigation measures outlined in 4.4.4 |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|--|
| <p>Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon</p> | <p>Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources can be mitigated effectively by scheduling such activities during periods of low tide, when work can be completed under shall water conditions or in the dry, thereby minimizing potential effects. No Project-related residual or cumulative effects on underwater noise conditions are expected. Underwater Noise and Fish and Fish Habitat are addressed in Sections 4.3 and 4.4 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.3.4 and 4.4.4</p> |

4.6 MARINE MAMMALS

Marine mammals, specifically harbor seals and sea lions, are known to use marine areas within the Project alignment. Other species of conversation interest, including southern resident killer whales, do not occur in the Fraser River. Underwater noise during construction is the key area of focus for potential Project-related effects on marine mammals. Underwater noise in the Fraser River South Arm from existing sources currently exceeds thresholds for disturbance to marine mammals approximately 20% of the time. The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.

Effects

A negligible effect on the availability of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

Mitigation

Apply standard industry and best management practices to activities such as pile driving that have the potential to generate underwater noise to ensure sound thresholds for the protection of marine mammals are adhered to.
 Marine Mammal Management Plan to be incorporated into the Construction Environmental Management Plan
 Monitor underwater noise.

Cumulative Effects

No significant Project-related residual or cumulative effects on marine mammals are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Semiahmoo has not voiced any specific issues or concerns with respect to Marine Mammals. | | | |

4.7 VEGETATION

The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development.

Project components and activities will be primarily located within the existing Highway 99 right-of-way, where the vegetation consists mainly of grassy, mowed verges. Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary marsh that occur in the vicinity of the Project. No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.

Effects

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to best management and environmental, terrestrial vegetation and wildlife management practices. Apply best practices such as flagging of at-risk ecosystems to avoid encroachment during construction.

Offset and enhance habitat. Create comparable habitat within the Project alignment to offset unavoidable potential Project-related effect, limited to a small reduction in area of the cattail march that overlaps with Project components. Replant disturbed areas with native species.

Invasive species management.

Cumulative Effects

No significant Project-related residual or cumulative effects on vegetation are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|--------------------------|---|
| Invasive plant species and proposed plans to manage presence during construction | Mitigation and management of invasive species are presented in Section 4.7 of the Application. The Ministry will develop and implement an Invasive Species Management Plan as part of the Construction Environmental Management Plan. | Addressed in Application | Implementation of mitigation measures outlined in Section 4.7.4 |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------------------------|---|
| Use of culturally significant plants in planting plans and importance of obtaining input from Semiahmoo on plant selection | Planting plans will be developed during later stages of Project planning and design. Opportunities for inclusion of culturally significant plants in in planting plans will be considered at that time. The Ministry will consult Aboriginal Groups on the development of these plans. | Addressed in Application | The Ministry will develop planting plans with consultation from Aboriginal Groups |

4.8 TERRESTRIAL WILDLIFE

The Highway 99 corridor is a highly developed area and terrestrial wildlife has generally adapted to this current condition. Terrestrial wildlife along Highway 99 consists primarily of raptors, riverine birds, and small mammals. Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge. No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.

Effects

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to terrestrial vegetation and wildlife management best practices such as spatial and temporal avoidance, pre-construction surveys and nest survey protocols, wildlife salvage and translocation, flagging and management of sensitive areas, and timing window restrictions.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term probability of barn swallow habitat loss during the construction period. The new bridge will provide new nesting opportunities for barn swallows.

There is a low, long-term probability of barn owl mortality.

No significant Project-related residual or cumulative effects on terrestrial wildlife are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|---------------------------------|--|
| <p>Potential light and noise effects on wildlife</p> | <p>The Ministry understands that Semiahmoo is concerned with the potential effects of light and noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |
| <p>Potential effects of the bridge structure on species such as waterfowl, migratory birds and bats</p> | <p>The Ministry understands that Semiahmoo is concerned with the potential effects of the new bridge structure on species such as mammals, waterfowl, bats, eagles and migratory birds. Installation of flight deflectors such as hedgerows at appropriate locations along the highlight will mitigate potential Project-related increase in traffic collision risk. Terrestrial Wildlife in addressed in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |

4.9 AIR QUALITY

Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in.

Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include a 35% reduction in particulate matter emissions, as compared with a 14% reduction without the Project; a 47% reduction in volatile organic compound emissions, as compared with a 40% reduction without the Project; and no exceedances of the current most stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.

The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.

Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.

Effects

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

Mitigation

Minimize effects through Project design.

Implement recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.

Development of an Air Quality and Dust Control Management Plan for inclusion of the Construction Environmental Management Plan.

Measure and monitor vehicle emissions and road dust during Project operation.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|------------------|-------------------------|
| <p>Effects of change in air quality resulting from increase in traffic volume due to the Project</p> | <p>Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in. Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. The new bridge will allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as the Tunnel portals, where they accumulate today. Effects on air quality during Project construction will be minimized through implementation of recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.</p> | <p>Addressed</p> | <p>None</p> |

4.10 ATMOSPHERIC NOISE

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the highway but do not exceed what is acceptable for residential, educational or institutional facilities.

Effects

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

Mitigation

Minimize effects through Project design.

Adhere to construction best practices and the Ministry’s 2014 *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways*.

Develop and implement a Noise Management Plan.

Residual & Cumulative Effects

With the application of mitigation, no significant Project-related residual or cumulative effects on atmospheric noise are expected

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|-------------------------------------|--|-----------|--|
| Potential noise effects on wildlife | The Ministry understands that Semiahmoo is concerned with the potential effects of noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application. | Addressed | Implementation of mitigation measures outlined in Section 4.8.4 (Terrestrial Wildlife Mitigation Measures) |

5.2 MARINE USE

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, and sorting and booming, as well as commercial, recreational and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place within the vicinity of the Project.

A clear span crossing of the Fraser River is proposed to avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span to improve navigation in and out of the slough.

Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.

Effects

A negligible effect on access to instream locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Develop and implement a Marine Access Management Plan to ensure that important marine use activities can be reconciled with temporary constraints associated with Project construction.

Establish communications protocols to advise in-stream construction activities.

Ensure appropriate lighting and marking for safe navigation.

Establish navigation protection zones during construction to avoid or minimize impact on marine use.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on Marine Access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|--------------------------|--|
| Potential effects of construction during fishing season on fishing activities. Impacts of Tunnel decommissioning on Aboriginal fisheries, specifically as it relates to timing | Potential interference with Semiahmoo fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined. The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided. | Addressed in Application | Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4 |

5.3 LAND USE

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta.

The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect regional growth trends or current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.

Once the new bridge becomes operational, recreational experience in its vicinity is expected to change due to improvements in local air quality, shoreline restoration of Deas Island, and re-vegetation of areas currently supporting highway infrastructure; improved connectivity across the Deas Island Regional Park resulting from removal of the Tunnel portals; and shading adjacent to the bridge, overhead noise, and changes in local viewsapes.

The Project will not result in changes to existing land use beyond small amounts of land, outside of the existing right-of-way, that area required for the Project.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Address temporary effects on existing land use during construction and incorporate land use considerations into a Traffic Management Plan.

Incorporate land use considerations into a Marine Access Management Plan.

Reconnect recreational trails.

Residual & Cumulative Effects

There is a high, short-term probability of disturbance to residential, commercial and industrial land uses.

There is a high, short-term probability of disturbance to recreational uses near the new bridge.

No significant Project-related residual or cumulative effects on Land Use are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Semiahmoo has not voiced any specific issues or concerns with respect to Land Use. | | | |

5.5 VISUAL QUALITY

The new bridge will add noticeable visual features to the landscape and will change visual conditions adjacent to the Project alignment. Replacement of interchanges also has the potential to change visual conditions of these locations. At distances greater than one kilometer, the bridge deck will merge with the natural landscape and the main visual features will be the bridge towers. Changes in visual quality at interchanges will be minor as visual quality in such areas is currently influenced by existing transportation infrastructure.

Effects

During construction, no to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

During operation, a measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Minimize effects through Project design.

Use of vegetated buffers to minimize visual effects to residential developments within close proximity to the bridge in Delta.

Residual & Cumulative Effects

There is a moderate, long-term probability of disturbance to visual quality.

No significant Project-related residual or cumulative effects on Visual Quality are expected

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Semiahmoo has not voiced any specific issues or concerns with respect to Visual Quality. | | | |

6.1 HERITAGE RESOURCES

The Project is located in an area where substantial historical development has occurred and the majority of the Project alignment is characterized as having low archaeological potential. No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

During construction, no to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

During operation, a measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Develop and implement a Heritage Resources Management Plan, which will include a change find procedure, to avoid impacts to previously unknown heritage resources that may be encountered during Project construction and operation.

Undertake additional archaeological surveys.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on heritage resources are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Protection of archaeological and heritage resources, including intangible heritage sites. Protection of cultural and archaeological sites that are known to exist or may be discovered within the Project area.</p> | <p>Ministry acknowledges that protection of archaeological sites as well as intangible heritage sites are of utmost importance to Semiahmoo. All Aboriginal Groups have been provided with a comprehensive list of these sites, the Archaeological Overview Assessment, the Archaeological Impact, and Heritage Resources Overview Assessment. Appropriate measures will be taken to ensure the protection of archaeological and heritage resources as outlined in Section 6.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures as outlined in Section 6.1.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|-----------|--|
| Participation in archaeological fieldwork and review of archaeological draft reports | Semiahmoo participated in all archaeological field work to date and was provided the opportunity to review draft archaeological reports. | Addressed | Semiahmoo will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports. |
| Concern that the Ministry's archaeological consultant will not work effectively with Semiahmoo First Nation based on experience on past projects | The Ministry worked with Semiahmoo to resolve this concern. | Addressed | None |

7.0 HUMAN HEALTH

Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health. The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options. The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased active and public transportation, improved traffic safety, improvement connectivity and access, improved emergency response, and economic development opportunities.

Future Project-related consultation with Aboriginal groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.

Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations, and emergency response.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

A negligible effect on access to instream locations for traditional use has been determined.

| 7.0 HUMAN HEALTH | | | |
|---|----------------------------------|---------------|--------------------------------|
| <p>A negligible effect on quality of experience tied to access of instream locations for traditional has been determined. A negligible effect on access to upland locations for traditional use has been determined. A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.</p> <p><u>Mitigation</u> Implement proven mitigation measures, effectively used during construction of projects such as the South Fraser Perimeter Road and Port Mann / Highway 1 Improvement, to ensure that temporary increases in ambient noise levels and air emissions during construction do not result in health effects. Implementation of mitigation measures outlined in Fish and Fish Habitat, Marine Mammals, Vegetation, Terrestrial Wildlife, Air Quality, Atmospheric Noise, Marine Use and Land Use.</p> <p><u>Residual & Cumulative Effects</u> No significant Project-related residual or cumulative effects on human health are expected.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Semiahmoo has not voiced any specific issues or concerns with respect to Human Health. | | | |

| 8.0 ACCIDENTS AND MALFUNCTIONS | | | |
|--|---|--------------------------|--|
| <p>Adherence to the practices and procedures contained in the Construction Environmental Management Plan will minimize the potential for accidents and malfunctions to occur.</p> <p>In general, replacement of the Tunnel with a new crossing and the proposed highway improvements are expected to lower the risk of accidents and malfunctions during highway operations and maintenance.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations | An Emergency Response and Spill Contingency Plan will outline how construction personnel will prevent, prepare for, respond to, and clean up spills | Addressed in Application | Implementation of mitigation measures outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan) |

| OTHER ISSUES | | | |
|---|--|--------------------------|---|
| Consultation with Semiahmoo First Nation identified issues outside of the environmental assessment process, Aboriginal Interests, Aboriginal Consultation, Aboriginal Participation and Project-Related Opportunities, and sections of the Application. | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Potential for contaminants in the tunnel and how this may affect tunnel decommissioning | The Ministry will consult with Fisheries and Oceans Canada and Port Metro Vancouver regarding Tunnel decommissioning, and will incorporate the requirements of these agencies in the planning and implementation of decommissioning activities. If potentially hazardous building materials are identified in the Tunnel, a detailed plan for removing and appropriately disposing of such material will be developed prior to initiating decommissioning activities. Any potentially hazardous material identified will be managed in accordance with applicable legislation, including the B.C. Hazardous Waste Regulation, B.C. Reg. 63/88, and the Workers' Compensation Board of B.C. Occupational Health and Safety Regulation, B.C. Reg. 296/97. | Addressed in Application | Implementation of mitigation measures outlined in 4.1.4 and 4.2.4 |
| Project will lead to increased traffic near the Peace Arch border crossing and that this will impact Semiahmoo First Nation's access to their community. | The Ministry understands that Semiahmoo First Nation currently has issues with respect to access to their community. The Project is not expected to result in an increase in traffic by the Peace Arch Border or to further contribute to existing community access issues. | Addressed | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|------------------|-------------------------|
| <p>Restricted access for emergency vehicles due to border traffic and from changes resulting from the Project.</p> | <p>The Ministry understands that Semiahmoo First Nation currently has issues with respect to access to their community. The Project is not expected to result in an increase in traffic by the Peace Arch Border or to further contribute to existing community access issues.</p> | <p>Addressed</p> | <p>None</p> |
| <p>Length of time tolls are in place</p> | <p>The Province intends to fund the Project, at least in part, through user tolls. This is consistent with the provincial tolling guidelines. Tolling recognizes that those directly benefitting from the new infrastructure in terms of time savings and reliability should help pay for the Project. This ensures that the needed improvements can proceed now, rather than years in the future when improvements will be even more overdue. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application.</p> | <p>Addressed</p> | <p>None</p> |

APPENDIX L

Squamish Nation

1.0 Introduction

This appendix provides a summary of the information presented in Part C Aboriginal Consultation (Part C) of the Application for an Environmental Assessment Certificate (the Application) regarding the assessment of effects on Aboriginal Interests. Aboriginal Interests are defined as asserted or determined Aboriginal rights, including title, or treaty rights. This appendix presents the information specific to Squamish Nation (Squamish).

The organization of the information presented generally follows Part C and includes the following sections:

- Consultation;
- Community Profile;
- Existing Conditions;
- Potential Effects;
- Mitigation;
- Residual Effects; and
- Summary and Conclusion.

For more detailed information on the effects assessment on Aboriginal Interests related to Squamish, refer to the following sections of Part C:

- Consultation with Squamish (**Section 10.1.2.10**);
- Squamish community profile (**Section 10.1.1.9**);
- Description of existing Squamish Aboriginal Interests (**Section 10.1.3.2**);
- Assessment of potential effects of the Project on the exercise of Squamish Aboriginal Interests (**Section 10.1.3.3**);
- Mitigation relating to potential effects on Aboriginal Interests (**Section 10.1.3.4**); and
- Residual effects on Squamish Aboriginal Interests following application mitigation (**Section 10.1.3.5**).

A summary of Aboriginal Interests Assessment for Squamish is also provided in **Section 10.1.3.8**.

The summary presented in this appendix also incorporated information found in the Squamish Overview Table (**Appendix L2**), which provides detailed information regarding:

- Squamish’s issues and concerns identified to date;
- Identification of potential effects on VCs and ICs that relate to the assessment of effects on Squamish’s Aboriginal Interests;
- The Ministry’s response to specific issues and concerns raised by Squamish;
- The status of these issues and concerns; and
- Next steps required to address outstanding issues and concerns.

2.0 Consultation

This section provides information regarding the consultation activities that the EAO and Ministry carried out prior to submission of the Application.

2.1 EAO-led Consultation Activities

2.1.1 Capacity Funding

When a provincial agency is a proponent of a project going through a provincial EA under the British Columbia *Environmental Assessment Act* (BCEAA), that agency provides funding to Aboriginal Groups to support their involvement in pre-Application and Application review phases in place of EAO providing such funding. The Ministry’s provision of capacity funding is discussed in the following section, Proponent-led Consultation Activities.

2.1.2 Participation in Working Group

EAO invited Squamish and all other Aboriginal groups identified in Schedule B of the Section 11 Order to participate as members of a Working Group. Squamish was invited to two EAO-led Working Group meetings, but did not attend.

Squamish also participated in the completeness review of the Application that considered whether the Application included information requirements set out in the Application Information Requirements.

It is anticipated that Squamish will continue as an active member of the Working Group through the environmental assessment process.

2.2 Proponent-led Consultation Activities

The Ministry began consultation with Squamish in early 2014 in order to identify the nature and scope of Squamish's Aboriginal Interests and how they might be impacted by the Project. Following is a summary of consultation activities led by the Ministry with Squamish. A more detailed discussion is provided under the Squamish section in Section 10.1.2.10 Overview of Consultation with each Schedule B Aboriginal Group. The following sections represent the main activities undertaken in support of Proponent-led consultation and include the following:

- Provision of capacity funding;
- Traditional use, traditional knowledge and other studies;
- Examples of Consultation Activities; and
- Concerns Identified to Date.

2.2.1 Capacity Funding

The Ministry entered into a Participation Funding Agreement, including the Initial Consultation and Pre-Application phases for consultation, with Squamish. The Ministry has been working with Squamish regarding their needs for capacity funding to facilitate their participation in the Application Review Phase. Consultation activities that are anticipated to be undertaken during the Application Review phase that will be supported by capacity funding include participation in technical reviews and analyses, involvement in ongoing consultation activities, and presentation of key information regarding their respective Aboriginal Interests.

2.2.2 Traditional Use, Traditional Knowledge & Other Studies

The Ministry provided additional funding to Squamish for the preparation and submission of the traditional use study *Review of George Massey Tunnel Project April 2016*. The purpose of such studies is to identify Aboriginal input and traditional knowledge for inclusion and consideration in the EA. In addition, studies were funded to enhance the Ministry's understanding of Aboriginal Interests and Aboriginal Group's past, present and desired future use as it pertains to the exercise of Aboriginal Interests within the Project area and the potential adverse effects on identified Aboriginal Interests.

2.2.3 Examples of Consultation Activities

A number of consultation activities were undertaken with Squamish during both the Initial Consultation Phase and the Pre-Application Consultation Phase as follows:

Initial Consultation Phase Activities - The Ministry recognized the importance and value of early engagement with Schedule B Aboriginal Groups and undertook an Initial Consultation Phase prior to the Pre-Application Phase. The Initial Consultation Phase concluded in December 16, 2015 with submission of Project Description and Key Areas of Study document. The focus of the Initial Consultation Phase was collection of baseline information and sharing of draft EA-related documents (i.e. Project Description and Areas of Study, draft Application Information Requirements (AIR)). The main consultation activities the Ministry undertook with Squamish included:

- Meetings with Squamish Nation staff and consultants;
- Sharing of Project-related materials;
- Sharing of draft documents for review and comment; and
- Provision of capacity funding to support participation in consultation activities, review of documents, and submission of comments and a Squamish Nation report.

Pre-Application Consultation Phase Activities - The Pre-Application Consultation Phase began with the filing of the Project Description and Key Areas of Study on December 16, 2015 and concluded with the submission of the Application. This phase included the issuance of the Section 11 Order, AIR development and collection of baseline information. The main consultation activities the Ministry undertook with Squamish included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Squamish;
- Funding for Squamish's participation in Project consultation activities and EA process;
- Meetings with Squamish leadership, staff, consultants, elders and membership;
- Squamish participation in fieldwork;
- Squamish participation in the EA Working Group;
- Review of draft EA documents such as the Application Information Requirements, Aboriginal Consultation Plan, and Aboriginal Consultation Reports; and
- Response and follow up with Squamish regarding the identification and resolution of issues.

2.2.4 Concerns Identified to Date

As outlined above, Squamish’s concerns, identified through consultation undertaken to-date, are presented in **Appendix L2 Squamish Nation Overview Table**. The Ministry’s response to Squamish’s key concerns regarding potential impacts on Squamish’s Aboriginal Interests are outlined below:

Table 1: Concerns Identified to Date

| Concerns Identified to Date | Response |
|--|---|
| Protection of Squamish First Nation’s rights to harvest within the Project area. | Squamish’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife), residual effects on the exercise of Aboriginal Interests by Squamish as a result of the Project are not expected. |
| Aboriginal participation and Project-related opportunities <ul style="list-style-type: none"> • Potential employment, training, contracting and economic development opportunities • Community preparedness • Cultural recognition and naming | The Ministry is committed to working with Squamish to identify potential employment, training, contracting and economic development opportunities and to identify ways to support community preparedness. The Ministry is exploring opportunities for cultural recognition and naming and will work with Squamish on these opportunities. |

| Concerns Identified to Date | Response |
|---|--|
| <p>Effects to fish and fish habitat</p> <ul style="list-style-type: none"> • Importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon • Potential effects of pile driving, blasting and underwater noise generated by Tunnel decommissioning and other construction activities | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon, salmon to Squamish and is committed to avoiding or mitigating any potential effects.</p> <p>The Ministry designed a clear span bridge over the Fraser River South Arm and Deas Slough to avoid or minimize Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Squamish’s Fisheries Department continues to be very helpful in the review of Green Slough concepts.</p> <p>As outlined in Section 4.3 (Underwater Noise), sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources will be effectively mitigated by scheduling activities during period of low tide, when work can be completed under shallow water conditions or in the dry.</p> |
| <p>Social effects of the Project on Squamish’s ability to transfer knowledge, language and participate in socio-cultural practices</p> | <p>Social effects of the Project on Squamish’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of Part C of the Application.</p> |

| Concerns Identified to Date | Response |
|--|--|
| Potential effects of construction during fishing season on fishing activities. Effects of construction and decommissioning-related barging activities on Squamish fishing. | Squamish’s access to the Fraser River and the potential to displace fishing vessels (access to river locations for traditional use as a result of changes to physical characteristics of these locations) is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8). Mitigation measures are outlined in Section 5.2.4 (Marine Use Mitigation Measures) of the Application. |
| Increased shipping | The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. |
| Potential effects on Fraser River flow rates after Tunnel removal | Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Flow rates are discussed in Section 4.1 (River Hydraulics). |
| Potential effects of run off and drainage | The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciate change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected. Sediment and Water Quality is addressed in Section 4.2 of the Application. |

3.0 Community Profile: Squamish Nation

Skwxwú7mesh Úxwumixw (Squamish Nation) describe themselves as the descendants of Coast Salish ancestors that lived in what are now known as the Greater Vancouver area, Gibson's Landing, and Squamish River watershed. The ancestral language of the Squamish Nation is *Skwxwú7mesh sníchim*.

Squamish Nation (*Skwxwú7mesh Úxwumixw*) has 24 reserves, with 2,232 of 4,176 registered members residing on Squamish Nation's reserve lands. The largest proportion of these on-reserve members live on the Squamish Nation's several urban reserves in the cities of Vancouver, North Vancouver, and West Vancouver, and the District of Squamish, with the most populated reserve being Mission 1, on the north shore of Burrard Inlet, bounded on the north and east by the City of North Vancouver. The Project area does not overlap any current or former Squamish Nation reserve lands.

Squamish Nation traditional territory, as described in their Statement of Intent filed with the British Columbia Treaty Commission, takes in the area from Point Grey in the south to Roberts Creek in the west; then north along the height of land to the Elaho River headwaters including all the islands and drainages in Howe Sound; then southeast to the confluence of the Soo and Green rivers north from Whistler; then south along the height of land to the Port Moody area including the entire Mamquam River and Indian Arm drainages; then west along the height of land to Point Grey. This territorial boundary, as updated from time to time, is asserted by Squamish Nation to extend farther south than described above, and specifically to the South Arm of the Fraser River, taking in all of Lulu Island. This area overlaps the northern half of the Project corridor, including the Tunnel crossing.

Xay Temixw (sacred land), the Squamish Nation's Land Use Plan, describes the Squamish Nation's vision for the future of the forests and wilderness of their traditional territory, with the stated objective to ensure the land is protected and managed for the benefit of present and future generations. *Xay Temixw* has established four land use zones: a forest stewardship zone, sensitive areas, restoration areas, and *Kwa kwayx welh-aynexws* (wild spirit places). *Xay Temixw* has also set management objectives that define how the lands, waters, and territory must be managed. Squamish Nation report that they are also undertaking planning for traditional fishing areas, but, due to the sensitivity of the information, may not be mapped or described in the plan.

The Squamish Nation owns and operates several businesses, including the Mosquito Creek Marina, Lynnwood Marina, Marina Grill, North Vancouver Smoke Shop at Mosquito Creek, Squamish Valley Gas LP, Superstore Gas Bar, North Vancouver, Capilano River RV Park, West Vancouver, and the Northwest Squamish Forestry LP. In addition to revenue generated from existing leases and businesses, the Squamish Nation plans to develop various parcels of lands, including proposed developments at Seymour, Capilano, Kitsilano, Chekwelp and Stawamus. The Squamish Nation also currently generates revenue from a three-year Forest Consultation and Revenue Sharing Agreement with the Province of British Columbia, signed in March 2015.

3.1 Squamish Aboriginal Interests: Existing Conditions

This section provides a high level of summary of past, present, and desired future use of the proposed Project area and surroundings for traditional purposes are or may be connected with the exercise of Squamish's Aboriginal Interests. A more detailed discussion, including sources used, is provided under Squamish in Section 10.1.3.2 Existing Conditions.

3.1.1 Fishing

- Squamish does not currently fish directly in the Fraser River for food, social or ceremonial (FSC) purposes based on information previously reported by Squamish and a review of Fisheries and Oceans Canada (DFO) records. According to those DFO records, Howe Sound and the Squamish River have been the key areas for Squamish salmon harvesting, and specifically within Pacific Fishery Management Area (PFMA) 28, subareas 28-2 to 28-4.
- Squamish has also been licenced to harvest crab, prawn, and shrimp for FSC purposes in PFMA 28-2 to 28-4, which is well north of the Fraser River.
- Squamish report that, historically, they harvested Fraser River sockeye, based on family ties with other First Nations, and that Squamish presence on the Fraser River is well documented in historic accounts, including one from 1827. They have said that there is no other source for sockeye in Squamish Nation territory, and that fishing sockeye on the Fraser is integral to Squamish Nation culture. Accordingly, for many years, including initiating a formal request to DFO in 2011, Squamish Nation say they have sought an increase to their Fraser River sockeye allocation for FSC purposes through an extension of their FSC fishing area to include the Lower Fraser River. Squamish Nation has said that by expanding their FSC fishing area to include the Lower Fraser River, they would be able to fish Fraser River sockeye the way their ancestors did (i.e., directly) and re-establish their historical connections to the area.

3.1.2 Hunting/Trapping

Past, present, or desired future hunting or trapping of resources by the Squamish Nation in the vicinity of the Project area was not identified in sources reviewed.

3.1.3 Gathering

Past, present, or desired future gathering of terrestrial resources by the Squamish Nation in the vicinity of the Project area was not identified in sources reviewed.

3.1.4 Archaeology and Cultural Heritage Interests

Archaeology and cultural heritage interests were not identified for Squamish in the vicinity of the Project area identified in the sources reviewed.

3.1.5 Other Related Interests

Other related interests were not identified for Squamish in the sources reviewed.

4.0 Potential Effects

This section provides a summary of the methodology used to identify potential adverse effects of the proposed Project on the exercise of Aboriginal Interests by Aboriginal Groups during Project construction and operation, followed by a summary of potential effects on Squamish's Aboriginal Interests, specifically. For a more detailed description of the methodology and a summary of the results, refer to **Section 10.1.3.3. Potential Effects**.

4.1 Methodology for Identification of Potential Effects

The first step in the effects assessment on Aboriginal interests was the identification of potential adverse effects on traditional use activities and related interests as a result of Project construction or operation. To evaluate these potential adverse effects, the findings of the following Valued Component (VC) chapters in Part B of the Application were considered, including identified mitigation measures, residual effects, cumulative effects and follow up strategies:

- **Section 4.4 Fish and Fish Habitat**
- **Section 4.6 Marine Mammals**
- **Section 4.7 Vegetation**
- **Section 4.8 Terrestrial Wildlife**
- **Section 5.2 Marine Use**

- **Section 5.3 Land Use**
- **Section 5.5 Visual Quality**
- **Section 6.1 Heritage Resources**
- **Section 7.1 Human Health**

The findings of the following Intermediate Component (IC) chapters were also considered in the assessment:

- **Section 4.1 River Hydraulics and River Morphology**
- **Section 4.2 Sediment and Water Quality**
- **Section 4.9 Air Quality**
- **Section 4.10 Atmospheric Noise**

The assessment of potential adverse effects of the Project on the exercise of Aboriginal Interests, including measures to address those effects, are presented in **Section 10.1.3.3** through **Section 10.1.3.5**, and largely applies the same methods used in Part B of the Application for the IC and VC assessments, as outlined **Section 3.0 Assessment Methodology**.

In addition to information from the VC and IC assessments that support the assessment of potential effects on Aboriginal Interests, information from a Health Impact Assessment (HIA) undertaken to support Project planning, including mitigation recommendations, has been integrated into the assessment of potential effects on Aboriginal Interests. The HIA for the Project can be found at <https://engage.gov.bc.ca/masseytunnel>. A summary of the key findings is provided in **Section 7.2 Health Impact Assessment**.

4.2 Selection of Indicators

Four parameters were chosen as indicators to understand and evaluate potential Project-related effects on the exercise of Aboriginal Interests. The rationale for their selection is presented in the following table.

Table 2 Indicators for the Aboriginal Interests Assessment

| Indicator | Rationale for Selection |
|---|---|
| Access to preferred locations for the exercise of Aboriginal Interests | Project components or activities could result in changes in access to or patterns of travel between traditional use locations on land or water |
| Availability of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in distribution or movement, relative abundance, or habitat area or composition of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in the real or perceived quality of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests | Project components or activities could result in: (1) direct sensory disturbance to traditional users (e.g., from noise, vibration); and/or (2) indirect changes to cultural practices, customs or traditions – i.e., cultural heritage or the expression and transfer of cultural values or ways of knowing (e.g., language, laws/governance, stories, spiritual beliefs) – tied to the cultural landscape or to the traditional use of specific traditional use locations or resources within that landscape. |

Potential adverse effects on the indicators noted above were analyzed in terms of the type and level of effect that Project components and activities may be expected to have on the exercise of Aboriginal Interests.

For the purposes of this assessment, no effect was understood to mean that no interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests would be expected. Where it was determined that an interaction, and potential effect, could occur, the following definitions were used to guide the characterization of the effect as negligible or measurable:

- Negligible – An interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests may occur, but modifications to the use of preferred options would not be expected.

- Measurable – Modifications to the exercise of Aboriginal Interests at preferred locations or in relation to preferred resources may be needed, and may be considered to be:
 - Minor (minimal or temporary modifications may be required to use preferred options),
 - Moderate (more frequent or longer term modifications may be required to use preferred options), or
 - Serious (permanent or indefinite modifications may be required potentially resulting in the loss of preferred options).

4.3 Identified Potential Effects

As noted above, the first step in evaluating potential adverse effects on Aboriginal Interests was a consideration of the findings for relevant Part B VCs, including identified mitigation measures, residual effects, cumulative effects and follow up strategies. The residual effects with the potential to result in an adverse effect on Aboriginal Interests are then carried forward in the assessment. Using the four indicators noted in the previous section, the potential Project-related effects and level of effect predicted in relation to Squamish’s exercise of Aboriginal Interests remaining after Part B mitigation are as follows:

Table 3 Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|---|--------------|------------|------------|------------|----------------------------|
| | Negligible | Measurable | Negligible | Measurable | |
| River locations for traditional use as a result of changes to physical characteristics of these locations | ✓ | | ✓ | | |
| Instream locations for traditional use | ✓ | | ✓ | | |
| Upland locations for traditional use | ✓ | | ✓ | | |

Table 4 Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|--|--------------|------------|------------|------------|----------------------------|
| | Negligible | Measurable | Negligible | Measurable | |
| Fish resources for traditional use | ✓ | | ✓ | | |
| Marine mammal resources for traditional use | ✓ | | ✓ | | |
| Terrestrial wildlife resources for traditional use | ✓ | | ✓ | | |
| Vegetation resources for traditional use | ✓ | | ✓ | | |

Table 5 Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|--|--------------|------------|------------|------------|----------------------------|

4.4 Potential Project-Related Effects on Squamish's Aboriginal Interests

Using the methodology presented in **Section 10.1.3.3 Potential Effects**, Table 7 provides the potential incremental Project-related effects, following mitigation of Project-related effects on Part B VCs and ICs as described in Part B, related to Squamish's Aboriginal Interests as summarized in Existing Conditions were identified for Project Construction and Operation. A discussion of potential Project-related effects on fishing, hunting/trapping, gathering and archaeology and cultural heritage follows the table.

Table 7 Summary of Potential Project-Related Effects

| Indicator | Potential Project-Related Effect |
|--|---|
| Project Construction | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • Potential temporary direct (minor) effect on quality of experience related to construction-related noise • Potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance |
| Project Operation | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • Potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses • Potential permanent direct (minor) effect on quality of experience related to traffic noise • Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses |

4.5 Fishing

Squamish does not currently fish directly in the Fraser River for food, social or ceremonial (FSC) purposes; however, Squamish report that they harvested Fraser River sockeye historically, based on family ties with other First Nations. Squamish also note that fishing sockeye on the Fraser is integral to Squamish Nation culture and have sought to increase to their Fraser River sockeye allocation for FSC purposes through an extension of their FSC fishing area to include the Lower Fraser River.

The proposed Project has the potential to affect fishing practices through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred fishing locations by Squamish, as a result of changes in river hydraulics or morphology, are expected to be negligible before mitigation. Potential changes in access to instream locations for fishing by Squamish during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to fishing locations by Squamish from instream construction activities are expected to be negligible. While it is acknowledged that Squamish has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Mitigation measures identified in the fish and fish habitat assessment to address Project-related effects on fish are expected to be effective at addressing potential effects on the availability of fishing resources preferred by Squamish. Further, as residual effects on fish identified in the fish and fish habitat assessment are not anticipated to affect population integrity, potential residual effects as a result of Project construction activities, would not be expected to measurably affect the availability of preferred fish resources.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of fishing resources preferred by Squamish; therefore, Potential Project-related effects on Squamish fishing would be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when fishing are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** are expected to largely address a potential Project-related effect to the quality of experience while fishing. At preferred fishing locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Squamish.

Section 5.5 Visual Quality predicts that residual effects to visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Squamish is fishing. As this landscape has been previously modified, the potential Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Squamish's Aboriginal Interests related to fishing are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.6 Hunting/Trapping

Past, present, or desired future hunting or trapping of resources by the Squamish Nation in the vicinity of the Project area was not identified in sources reviewed.

The proposed Project has the potential to affect hunting and trapping through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred hunting and trapping locations by Squamish as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for hunting and trapping by Squamish during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to hunting and trapping locations by Squamish from instream construction activities, are expected to be negligible. While it is acknowledged that Squamish has reported a desire for higher levels of use in this portion of the river based on historic use, the

episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for hunting and trapping by Squamish resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with hunting and trapping locations.

Mitigation measures identified in the marine mammal and terrestrial wildlife assessments are expected to be effective at addressing potential effects on the availability of hunting and trapping resources preferred by Squamish. Therefore, Project-related effects on hunting and trapping related to potential changes in the availability of resources would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for hunting and trapping by Squamish; therefore, Potential Project-related effects on Squamish fishing would be expected to be negligible.

Project operation is not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when hunting and trapping are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** to address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while hunting and trapping. At preferred hunting and trapping locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Squamish.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Squamish is hunting and trapping. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Squamish's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.7 Gathering

Past, present, or desired future gathering of terrestrial resources by the Squamish Nation in the vicinity of the Project area was not identified in sources reviewed.

The proposed Project has the potential to affect gathering through changes in access to preferred locations, changes in availability of preferred resources, changes in quality of preferred resources and changes in quality of experience when gathering.

Potential changes in access to preferred gathering locations by Squamish as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for gathering by Squamish during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to gathering locations by Squamish from instream construction activities, are expected to be negligible. While it is acknowledged that Squamish has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for gathering by Squamish resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with gathering locations.

Mitigation measures identified in the vegetation assessment to address Project-related effects on terrestrial vegetation are expected to be effective at addressing potential effects on the availability of resources for the exercise of Aboriginal Interests related to gathering. Therefore, Project-related effects on gathering related to potential changes in the availability of vegetation would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in Section 4.2 Sediment and Water Quality and Section 4.9 Air Quality are expected to be effective at addressing potential effects on the quality of preferred resources for gathering by Squamish; therefore, Potential Project-related effects on gathering related to potential changes in the quality of resources would therefore be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when gathering are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while gathering. At preferred gathering locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Squamish.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Squamish is gathering. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Squamish's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.8 Archaeology and Cultural Heritage Interests

Archaeology and cultural heritage interests were not identified for Squamish in the vicinity of the Project area identified in the sources reviewed.

The proposed Project has the potential to affect Squamish's Aboriginal Interests related to archaeology and cultural heritage through changes in access to preferred locations and changes in quality of experience.

Potential changes in access to locations related to Squamish's archaeological and cultural heritage interests as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations related to Squamish's interests related to archaeology and cultural heritage during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to locations related to Squamish’s archaeological and cultural heritage interests from instream construction activities are expected to be negligible. While it is acknowledged that Squamish has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations related to Squamish’s archaeological and cultural heritage interests resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and not expected to overlap with locations related to Squamish’s archaeological and cultural heritage interests.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** would also be expected to address the potential Project-related effect to the quality of experience while undertaking activities related to cultural heritage. At locations related to Squamish’s archaeological and cultural heritage interests that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Squamish.

As reported in **Section 6.1 Heritage Resources**, no archaeological or historical sites were identified within the Project area during fieldwork; however, there may be other locations with intangible cultural value or meaning to Squamish (e.g., spiritual or storied sites, named places) potentially affected by the Project. In addition, physical alterations to the landscape may affect archaeological or historical sites, and how this landscape is experienced culturally.

As a result, mitigation measures proposed in Part B are not expected to address a potential incremental and permanent Project-related effect tied to Squamish’s Aboriginal Interests related to archaeology and cultural heritage that may be associated with the introduction of a new prominent feature to the cultural landscape. As this landscape has been previously modified by anthropogenic changes, the potential incremental Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal, but permanently disruptive for Squamish, who have identified a historical connection to, and continued or desired use of, sites or places that help define the cultural landscape in the Project area.

Additional mitigation to address this potential incremental effect that is not otherwise addressed in the Application is proposed in **Section 10.1.3.4** and summarized below under Mitigation.

5.0 Mitigation

This section provides a summary of mitigation measures identified to address potential Project-related effects on the exercise of Aboriginal Interests by Squamish. For a more detailed discussion, refer to **Section 10.1.3.4 Mitigation**.

Mitigation measures identified for the relevant VCs and ICs in Part B of the Application were reviewed to assess their effectiveness at addressing potential Project-related effects on the exercise of Aboriginal Interests related to those VCs. Examples of mitigation that are proposed in the Application to address potential effects on VCs and ICs, with the potential to result in an effect on Aboriginal Interests, include:

- Avoiding fisheries sensitive timing windows during key Project activities.
- Developing a Marine Access Management Plan to ensure marine use activities, including those supporting Aboriginal Interests, can continue during Project construction.
- Scheduling activities with the potential to generate underwater noise to avoid potential effects on marine mammals.
- Development and implementation of a Terrestrial Vegetation and Wildlife Management Plan with measures to minimize disturbance and loss of vegetation, prevent soil compaction, and minimize clearing in order to minimize effects on vegetation.

These measures are expected to be largely effective at avoiding, reducing, or otherwise managing potential Project-related effects on the exercise of Aboriginal Interests during Project construction and operation.

Recognizing some measurable effects on Squamish's Aboriginal Interests could remain following the application of mitigation to address potential effects on the relevant VCs and ICs in Part B, the following additional measures have been identified to address such effects:

- Ongoing consultation with Squamish regarding proposed measures, management plans, and monitoring programs related to intermediate components and valued components assessments; and
- Development of a Cultural Heritage Management Plan.

6.0 Residual Effects

With the implementation of mitigation measures identified in **Section 10.1.3.4** and summarized above, residual adverse effects of the proposed Project on the exercise of Aboriginal Interests are expected to be negligible (i.e., not measurable or detectable), and are not further assessed.

7.0 Summary and Conclusion

Part C of the Application builds on consultation undertaken to date to understand Squamish's Aboriginal Interests and provides for an assessment of potential Project-related effects of the Project on Aboriginal Interests.

The Ministry began consultations with Squamish prior to the submission of the Project Description, which is the end of the Initial Consultation Phase. Both EAO and the Ministry consulted with Squamish during the Pre-Application Phase, which concluded with the submission of the Application. The main concerns expressed by Squamish during consultations include:

- Protection of Squamish First Nation's rights to harvest within the Project area.
- Aboriginal participation and Project-related opportunities
- Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon;
- Evaluation on impacts to ecological services for all ecosystems within the vicinity of the Project;
- Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon;
- Disturbance to benthic and aquatic invertebrates and their habitat;
- Social effects of the Project on Squamish's ability to transfer knowledge, language and participate in socio-cultural practices;
- Potential effects of construction during fishing season on fishing activities. Effects of construction and decommissioning-related barging activities on Squamish fishing;
- Increased shipping;
- Potential effects on Fraser River flow rates after Tunnel removal; and
- Potential effects of run off and drainage.

Based on information provided by Squamish and other publicly-available sources, the Ministry developed a summary of past, present and desired future use of the proposed Project area and its surroundings for the purposes of fishing, hunting/trapping, gathering, archaeology and cultural heritage interests and other related interests.

Relying first on the results of the effects assessments for related VCs and ICs in Part B, the assessment of potential effects of Squamish's Aboriginal Interests considered four indicators:

1. Access to preferred locations for the exercise of Aboriginal Interests;
2. Availability of preferred resources for the exercise of Aboriginal Interests;
3. Quality of preferred resources for the exercise of Aboriginal Interests; and
4. Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests.

As reviewed in **Section 10.1.3.3** and **Section 10.1.3.4**, the mitigation measures, management plans, and monitoring programs identified in Part B of the Application for VCs or ICs linked to the exercise of Aboriginal Interests are expected to be largely effective at addressing the incremental Project-related effects noted above on the exercise of Aboriginal Interests by Squamish Nation, except in the following potentially measurable cases:

- Project construction:
 - Potential temporary direct (minor) effect on quality of experience related to construction-related noise and a potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance
- Project operation:
 - Potential permanent direct (minor) effect on quality of experience related to traffic noise and a potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses
 - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses

The following additional measures have been identified to address the above-noted effects:

- Ongoing consultation with Squamish regarding proposed measures, management plans, and monitoring programs related to VCs and ICs assessments; and
- Development of a Cultural Heritage Management Plan.

With the implementation of mitigation proposed to address potential effects on VCs and ICs, as well as additional mitigation proposed to address potential residual effects on Aboriginal Interests, no effects on the exercise of Aboriginal Interests by Squamish, as a result of the Project, are expected.

ENVIRONMENTAL ASSESSMENT PROCESS

An environmental assessment of the Project is required under the B.C. *Environmental Assessment Act* (B.C. *EAA*), S.B.C. 2002, c. 43, and permits to construct and operate can only be received once the environmental assessment process is complete and an Environmental Assessment Certificate (EAC) has been issued. If the Project is approved, an EAC will be awarded to and held by the Ministry. The Reviewable Projects Regulation B.C. Reg. 370/2002 under the B.C. *EAA* sets out the criteria for reviewable projects.

On December 16, 2015, the B.C. Environmental Assessment Office (EAO) issued a Section 10(1)(c) Order confirming that the Project is a reviewable project pursuant to the B.C. *EAA*, and that it requires an EAC.

The Project as proposed is not subject to review under the *Canadian Environmental Assessment Act, 2012*, S.C. 2012, c. 19, s. 52, since it does not meet the definition of a physical activity under the Schedule of Physical Activities in the Regulations Designating Physical Activities SOR/2012-147.

EAO is a neutral agency that manages the review of proposed major projects in British Columbia, as required by the *Environmental Assessment Act*.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---------------------------|--------|-------------------------|
| Squamish did not voice any issues or concerns regarding the Environmental Assessment Process. | | | |

ABORIGINAL INTERESTS

There are potential Project related impacts to Squamish's title, Rights and culture. Potential effects and the level of effect predicted include:

1. Access to preferred locations for the exercise of Aboriginal Interests (access to river locations for traditional use as a result of changes to physical characteristics of these locations).
2. Availability of preferred resources for the exercise of Aboriginal Interests (availability of fish, marine mammal, vegetation and terrestrial wildlife resources for Traditional Use).
3. Quality of preferred resources for the exercise of Aboriginal Interests (quality of water used for cultural purposes, quality of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use).
4. Quality of experience of exercising, or tied to the exercise, of Aboriginal Interests (quality of experience tied to the traditional use of river locations as a result of changes to the physical characteristics of the location; quality of experience tied to access of instream and upland areas locations for traditional use; quality of experience tied to use of water for traditional purposes; quality of experience tied to the traditional use of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use; and quality of experience while engaged in or tied to traditional use as a result of changes in air quality, noise, ground-borne vibration and to the cultural landscape).

Measureable Effects

Access for traditional use

- Cultural landscape
- Instream locations (during construction)

Quality of experience while engaged in or tied to traditional use

- cultural landscape
- Instream locations (during construction)

No, Negligible or Moderate Effects

Quality of experience while engaged in or tied to traditional use

- Noise

Negligible Effects

Access for traditional use

- Instream locations
- River locations
- Upland locations

ABORIGINAL INTERESTS

Quality for Traditional Use

- Water
- Fish resources
- Marine mammal resources
- Vegetation resources

Quality of experience while engaged in or tied to traditional use

- Fish resources
- Instream locations (during construction)
- Marine mammal resources
- River locations
- Terrestrial wildlife resources
- Upland locations
- Water
- Vegetation resources

Availability for Traditional Use

- Fish resources
- Marine mammal resources
- Terrestrial wildlife resources
- Vegetation resources

No to Negligible Effects

Quality of experience while engaged in or tied to traditional use

- changes to the cultural landscape

No or Negligible Effects

Quality of experience while engaged in or tied to traditional use

- Air quality
- Ground-borne vibration

ABORIGINAL INTERESTS

High, Short-term Probability of Effect

- Disturbance to residential, commercial and industrial land uses
- Disturbance to recreational uses near the new bridge

Moderate, Long-term Probability of Effect

- Disturbance to visual quality

Low, Short-term Probability of Effect

- Barn swallow habitat loss (construction period)
- Physical injury or mortality to fish through crushing or entrainment (construction period)

Low, Long-term Probability of Effect

- Barn owl mortality

No Significant Residual or Cumulative Effects

- Air quality
- Fish and fish habitat
- Heritage resources
- Marine access
- Marine mammals
- River hydraulics and river morphology
- Sediment and water quality
- Terrestrial Wildlife
- Vegetation

With this ongoing engagement, residual effects on the exercise of Aboriginal Interests or other matters of concern as a result of the Project are not expected.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Capacity funding to facilitate participation in the Project review process | Squamish received funding for the Pre-Application Phase. The Ministry will provide further funding for the Application Review Phase. | Addressed | Consultation regarding funding for the Application Review Phase |
| Funding for Project Report | The Ministry signed a funding agreement with Squamish Nation which provided funding for a GMT Project Report. | Addressed | None |

ABORIGINAL PARTICIPATION AND PROJECT-RELATED OPPORTUNITIES

The Ministry is actively exploring opportunities to provide benefits, economic and non-economic, to Aboriginal Groups that are directly affected by the Project. Opportunities include employment, training, and contracting as well as participation in environmental enhancement and other components of the Project.

Prior to the Pre-Application Phase of the Project, the Ministry worked with Schedule B Aboriginal Groups to determine appropriate tools to support consultation. Consultation activities were based on the specific needs and preferences of these Aboriginal Groups and the Consultation Plan included individualized plans that were co-developed and reviewed.

The Project’s Aboriginal Consultation Plan has been developed in consultation with Schedule B Aboriginal Groups, in order to meet the Aboriginal consultation requirements as delegated by EAO and to maintain and, where possible, enhance positive working relationships between the Ministry and the respective Aboriginal Groups.

The objectives and requirements of the Aboriginal Consultation Plan are to:

- Provide relevant Project-related information in a timely and effective manner that supports an understanding of the nature of the Project and its potential adverse effects on Aboriginal Interests
- Plan and implement mutually acceptable consultation activities that support effective participation of Aboriginal communities in the EA as well as related regulatory and permitting processes

Establish and maintain dialogue throughout the EA as a means of providing opportunities to respond to outstanding concerns.

Provide opportunities for Aboriginal Groups to share views of the Project with the Ministry and EAO within reasonable timeframes.

Provide opportunities for Aboriginal Groups to identify potential adverse effects of the proposed Project on Aboriginal Interests, including cumulative effects and, to the extent appropriate, develop ways to mitigate or otherwise accommodate potential adverse effects

Involve Aboriginal Groups, where possible, in relevant studies including, but not limited to, archaeological fieldwork.

Incorporate community and traditional knowledge in Project components

Document and report to EAO on the Ministry’s Aboriginal consultation program at times specified by EAO.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------|--|
| Opportunities for cultural recognition and naming, specifically interpretive signage by highway including road signs and kiosks | The Ministry is exploring opportunities for cultural recognition and naming and will to work with Squamish on this matter. | Ongoing | Discussion with Squamish to explore opportunities related to cultural recognition and naming, art and interpretive signage |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------|--|
| Project-related employment, training, contracting, and economic development opportunities. | The Ministry is committed to working with Squamish to identify potential opportunities to benefit from the. Ministry acknowledges that Aboriginal Groups want to prepare their membership for employment opportunities and will work with Squamish to identify ways to support community preparedness. | Ongoing | The Ministry will share information as it becomes available to support community preparedness and welcomes input from Aboriginal Groups on the type of information that would be useful. |

4.1 RIVER HYDRAULICS

The proposed bridge will have a clear-span, which eliminates potential changes to river hydraulics or river morphology resulting from the new structure. The Fraser River South Arm is dynamic with scour in the order of several metres during freshet and migrating sand dunes with heights of up to four metres. Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. Tunnel removal is expected to result in temporary bed lowering between the Tunnel and Lulu Island-Delta water main; however, no permanent effect on the Lulu Island-Delta watermain is expected.

Effects

A negligible effect to access to river locations for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of river locations has been determined.

Mitigation

Monitor the riverbed within 100 metres upstream and downstream of the watermain.

Stockpile appropriately-sized rock near the Project site, for priority scour protection repairs at the water main crossing.

Establish on-call contracts with a qualified registered professional and a qualified marine contractor prior to Tunnel removal, to ensure that scour protection repairs can be designed and implemented on short notice

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|--------------------------|--|
| Change in flow rates after Tunnel removal | Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. | Addressed in Application | Implementation of mitigation measures outlined in Section 4.1.4 (River Hydraulics Mitigation Measures) |

4.2 SEDIMENT AND WATER QUALITY

The proposed bridge will have a clear-span, which reduces potential effects to sediment and water quality within the Fraser River South Arm. During Tunnel decommissioning, a minor, temporary increase in turbidity, as compared with baseline conditions, is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.

Effects

A negligible effect on quality of water used for cultural purposes has been determined.

A negligible effect on quality of experience tied to use of water for cultural purposes has been determined.

Mitigation

Avoid effects through Project design.

Incorporate a stormwater collection and distribution system (stormwater detention ponds and biofiltration swales) into bridge design that will convey and discharge stormwater runoff to appropriate upland infrastructure for proper treatment.

Develop Construction Environmental Management and Operational Environmental Management plans.

Control suspended sediment during Tunnel decommissioning. Employment of construction methods that minimize levels of Project-induced turbidity. Use spoil barges equipped with sediment containment system (filter cloth, concrete lock blocks, straw bales) to transport removed material off-site.

Control suspended sediment during Project construction in and adjacent to Deas and Green Sloughs. Use of sediment control measures such as turbidity curtains and de-watered cofferdams.

Monitor water quality during construction.

Use timing windows for undertaking in-stream works.

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology or sediment and water quality are expected.

| <p>Water quality and sediment issues: comprehensive understanding of potential ecological impacts and core sampling</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciative change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected. Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.2.4</p> |

4.4 FISH AND FISH HABITAT

The proposed bridge will have a clear span over the Fraser River South Arm and Deas Slough, avoiding or minimizing Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Given the disturbed nature of much of the Project alignment, re-vegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by improvements to local water quality; removal of non-native species; and replanting with species that provide habitat value for fish and wildlife.

Effects

- A negligible effect on the availability of fish resources for traditional use has been determined.
- A negligible effect on quality of fish resources for traditional use has been determined.
- A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

Mitigation

- Avoid effects through Project design.
- Apply best management and environmental management practices.
- Develop Construction Environmental Management and Operational Environmental Management plans.
- Use timing windows for undertaking in-stream works.
- Erosion and sediment control.
- Habitat enhancement and offsetting.

Residual & Cumulative Effects

- There is a low, short-term probability of physical injury or mortality to fish through crushing or entrainment during the construction period.
- No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|------------------|--|
| <p>Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon. New studies have proven that hard surface runoff from roads will kill salmon within two hours of exposure.</p> | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon and salmon to the Squamish. Potential Project-related effects on fish and fish habitat are presented in Section 4.4 of the Application.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in 4.4.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|------------------|--|
| <p>Evaluation on impacts to ecological services for all ecosystems within the vicinity of the Project</p> | <p>Pacific salmon species selected for Project-related baseline studies include Chinook salmon, Chum salmon, Coho salmon, Pink salmon, and Sockeye salmon. Using existing scientific and literature, baseline conditions will be described for all life history stages of each salmon species, with emphasis on those life history stages that use aquatic habitats within the Project Area. Fish sampling focused on potential rearing values within drainage ditches in Richmond and Delta, for which limited existing inventory information exists, has been incorporated into the baseline studies.</p> | <p>Addressed</p> | <p>None</p> |
| <p>Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon.</p> | <p>Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources can be mitigated effectively by scheduling such activities during periods of low tide, when work can be completed under shall water conditions or in the dry, thereby minimizing potential effects. No Project-related residual or cumulative effects on underwater noise conditions are expected. Underwater Noise and Fish and Fish Habitat are addressed in Sections 4.3 and 4.4 of the Application.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in 4.3.4 and 4.4.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|------------------|--|
| <p>Disturbance to benthic and aquatic invertebrates and their habitat</p> | <p>Aquatic habitats, which include habitat for fish and other aquatic species (including benthic and aquatic invertebrates), will be a primary area of focus for the environmental assessment of the Project.</p> <p>Potential disturbance to benthic and aquatic invertebrates is not, on its own, proposed as a key area of study given the nature of the project and the aquatic habitats it overlaps with. Aquatic habitats overlapping with the Project occur within a section of the Fraser River that is dynamic, influenced by large flow variations and downstream transport of sand and organic matter. Therefore, aquatic and benthic invertebrate communities in the Project Area are expected to be resilient to physical disturbance. Given the temporary and short-term changes in flow and water quality expected from Project activities, it is anticipated that the benthic and aquatic invertebrates will recover rapidly from disturbance.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in 4.4.4</p> |

4.6 MARINE MAMMALS

Marine mammals, specifically harbor seals and sea lions, are known to use marine areas within the Project alignment. Other species of conversation interest, including southern resident killer whales, do not occur in the Fraser River. Underwater noise during construction is the key area of focus for potential Project-related effects on marine mammals. Underwater noise in the Fraser River South Arm from existing sources currently exceeds thresholds for disturbance to marine mammals approximately 20% of the time. The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.

Effects

- A negligible effect on the availability of marine mammal resources for traditional use has been determined.
- A negligible effect on quality of marine mammal resources for traditional use has been determined.
- A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

Mitigation

- Apply standard industry and best management practices to activities such as pile driving that have the potential to generate underwater noise to ensure sound thresholds for the protection of marine mammals are adhered to.
- Marine Mammal Management Plan to be incorporated into the Construction Environmental Management Plan
- Monitor underwater noise.

Cumulative Effects

No significant Project-related residual or cumulative effects on marine mammals are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Squamish did not voice any issues or concerns regarding Marine Mammals | | | |

4.7 VEGETATION

The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development.

Project components and activities will be primarily located within the existing Highway 99 right-of-way, where the vegetation consists mainly of grassy, mowed verges. Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary marsh that occur in the vicinity of the Project. No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.

Effects

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to best management and environmental, terrestrial vegetation and wildlife management practices. Apply best practices such as flagging of at-risk ecosystems to avoid encroachment during construction.

Offset and enhance habitat. Create comparable habitat within the Project alignment to offset unavoidable potential Project-related effect, limited to a small reduction in area of the cattail march that overlaps with Project components. Replant disturbed areas with native species.

Invasive species management.

Cumulative Effects

No significant Project-related residual or cumulative effects on vegetation are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|--------------------------|---|
| Invasive plant species and proposed plans to manage presence during construction | Mitigation and management of invasive species are presented in Section 4.7 of the Application. The Ministry will develop and implement an Invasive Species Management Plan as part of the Construction Environmental Management Plan. | Addressed in Application | Implementation of mitigation measures outlined in Section 4.7.4 |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|--------------------------|---|
| Use of culturally significant plants in planting plans and importance of obtaining input from Squamish on plant selection | Planting plans will be developed during later stages of Project planning and design. Opportunities for inclusion of culturally significant plants in in planting plans will be considered at that time. The Ministry will consult Aboriginal Groups on the development of these plans. | Addressed in Application | The Ministry will develop planting plans with consultation from Aboriginal Groups |

4.8 TERRESTRIAL WILDLIFE

The Highway 99 corridor is a highly developed area and terrestrial wildlife has generally adapted to this current condition. Terrestrial wildlife along Highway 99 consists primarily of raptors, riverine birds, and small mammals. Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge. No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.

Effects

- A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.
- A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.
- A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

Mitigation

- Minimize potential effects through Project design.
- Adhere to terrestrial vegetation and wildlife management best practices such as spatial and temporal avoidance, pre-construction surveys and nest survey protocols, wildlife salvage and translocation, flagging and management of sensitive areas, and timing window restrictions.
- Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term probability of barn swallow habitat loss during the construction period. The new bridge will provide new nesting opportunities

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|--|
| <p>Potential light and noise effects on wildlife and fish.</p> | <p>The Ministry understands that Squamish is concerned with the potential effects of light and noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|--------------------------|---|
| Potential effects of the bridge structure on species such as waterfowl and migratory birds. | The Ministry understands that Squamish is concerned with the potential effects of the new bridge structure on species such as mammals, waterfowl, bats, eagles and migratory birds. Installation of flight deflectors such as hedgerows at appropriate locations along the highlight will mitigate potential Project-related increase in traffic collision risk. Terrestrial Wildlife in addressed in Section 4.8 of the Application. | Addressed in Application | Implementation of mitigation measures outlined in Section 4.8.4 |

4.9 AIR QUALITY

Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in.

Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include a 35% reduction in particulate matter emissions, as compared with a 14% reduction without the Project; a 47% reduction in volatile organic compound emissions, as compared with a 40% reduction without the Project; and no exceedances of the current most stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.

The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.

Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.

Effects

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

Mitigation

Minimize effects through Project design.

Implement recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.

Development of an Air Quality and Dust Control Management Plan for inclusion of the Construction Environmental Management Plan.

Measure and monitor vehicle emissions and road dust during Project operation.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Squamish did not voice any issues or concerns regarding the Air Quality. | | | |

4.10 ATMOSPHERIC NOISE

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the highway but do not exceed what is acceptable for residential, educational or institutional facilities.

Effects

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

Mitigation

Minimize effects through Project design.

Adhere to construction best practices and the Ministry’s 2014 *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways*.

Develop and implement a Noise Management Plan.

Noise monitoring program.

Site specific schedules and activities.

Residual & Cumulative Effects

With the application of mitigation, no significant Project-related residual or cumulative effects on atmospheric noise are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Squamish did not voice any issues or concerns regarding the Atmospheric Noise. | | | |

5.2 MARINE USE

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, and sorting and booming, as well as commercial, recreational and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place within the vicinity of the Project.

A clear span crossing of the Fraser River is proposed to avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span to improve navigation in and out of the slough.

Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.

Effects

During construction, a measureable effect on access to instream locations for traditional use has been determined.

During construction, a measurable effect on quality of experience tied to access of instream locations for traditional has been determined.

During operation, a negligible effect on access to instream locations for traditional use has been determined.

During construction, a negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Develop and implement a Marine Access Management Plan to ensure that important marine use activities can be reconciled with temporary constraints associated with Project construction.

Establish communications protocols to advise in-stream construction activities.

Ensure appropriate lighting and marking for safe navigation.

Establish navigation protection zones during construction to avoid or minimize impact on marine use.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Potential effects of construction during fishing season on fishing activities. Impacts of Tunnel decommissioning on Aboriginal fisheries, specifically as it relates to timing.</p> | <p>Potential interference with Squamish fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> <p>The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4</p> |
| <p>Fishing patterns and practices have adapted to the Tunnel in the riverbed. Removal of the Tunnel would impact these established patterns and practices</p> | <p>As discussed in Section 4.4 (Fish and Fish Habitat) of the Application, potential effects on habitat quality associated with decommissioning of the existing Tunnel are considered negligible. Sensitive life stages of salmonids migrating through or foraging in this section of the river tend to occupy the upper water column, and eulachon spawning habitat is absent near the Tunnel crossing, while sturgeon overwintering habitat will continue to be present after the trench has naturally infilled. As a result, potential Project-related effects associated with fish habitat alteration are not considered further in the assessment.</p> | <p>Addressed</p> | <p>None</p> |

5.3 LAND USE

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta.

The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect regional growth trends or current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.

Once the new bridge becomes operational, recreational experience in its vicinity is expected to change due to improvements in local air quality, shoreline restoration of Deas Island, and re-vegetation of areas currently supporting highway infrastructure; improved connectivity across the Deas Island Regional Park resulting from removal of the Tunnel portals; and shading adjacent to the bridge, overhead noise, and changes in local viewsapes.

The Project will not result in changes to existing land use beyond small amounts of land, outside of the existing right-of-way, that area required for the Project.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Address temporary effects on existing land use during construction and incorporate land use considerations into a Traffic Management Plan.

Incorporate land use considerations into a Marine Access Management Plan.

Reconnect recreational trails.

Residual & Cumulative Effects

There is a high, short-term probability of disturbance to residential, commercial and industrial land uses.

There is a high, short-term probability of disturbance to recreational uses near the new bridge.

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Squamish did not voice any issues or concerns regarding Land Use | | | |

5.5 VISUAL QUALITY

The new bridge will add noticeable visual features to the landscape and will change visual conditions adjacent to the Project alignment. Replacement of interchanges also has the potential to change visual conditions of these locations. At distances greater than one kilometer, the bridge deck will merge with the natural landscape and the main visual features will be the bridge towers. Changes in visual quality at interchanges will be minor as visual quality in such areas is currently influenced by existing transportation infrastructure.

Effects

No to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

A measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Minimize effects through Project design.

Use of vegetated buffers to minimize visual effects to residential developments within close proximity to the bridge in Delta.

Residual & Cumulative Effects

There is a moderate, long-term probability of disturbance to visual quality.

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---------------------------|--------|-------------------------|
| Squamish has not voiced specific concerns regarding Visual Quality. | | | |

| 6.1 HERITAGE RESOURCES | | | |
|--|--|---------------------------------|---|
| <p>The Project is located in an area where substantial historical development has occurred and the majority of the Project alignment is characterized as having low archaeological potential. No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.</p> <p><u>Effects</u> A negligible effect on access to upland locations for traditional use has been determined. A negligible effect on quality of experience tied to access of upland locations for traditional has been determined. No to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape. A measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.</p> <p><u>Mitigation</u> Develop and implement a Heritage Resources Management Plan, which will include a change find procedure, to avoid impacts to previously unknown heritage resources that may be encountered during Project construction and operation. Undertake additional archaeological surveys.</p> <p><u>Residual & Cumulative Effects</u> No significant Project-related residual or cumulative effects on heritage resources are expected.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| <p>Protection of archaeological and heritage resources, including intangible heritage sites. Protection of cultural and archaeological sites that are known to exist or may be discovered within the Project area.</p> | <p>Ministry acknowledges that protection of archaeological sites as well as intangible heritage sites are of utmost importance to Squamish. All Aboriginal Groups have been provided with a comprehensive list of these sites, the Archaeological Overview Assessment, the Archaeological Impact, and Heritage Resources Overview Assessment. Appropriate measures will be taken to ensure the protection of archaeological and heritage resources as outlined in Section 6.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures as outlined in Section 6.1.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------|---|
| Participation in archaeological fieldwork and review of archaeological draft reports | Squamish participated in all archaeological field work to date and was provided the opportunity to review draft archaeological reports. | Addressed | Squamish will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports. |

7.0 HUMAN HEALTH

Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health. The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options. The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased active and public transportation, improved traffic safety, improvement connectivity and access, improved emergency response, and economic development opportunities.

Future Project-related consultation with Aboriginal groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.

Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations, and emergency response.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

During construction, a measureable effect on access to instream locations for traditional use has been determined.

During construction, a measurable effect on quality of experience tied to access of instream locations for traditional has been

|--|---|------------------|-------------------------|
| <p>Scope of pollution testing was one km from work zone. However, increases in traffic from this route will have a long ranging, long term impact through the East to the Fraser Valley. The projection graphs do not predict what the maximum capacity of the route once completed. Is such a projection available to ascertain outcomes?</p> | <p>The future conditions for the Air Quality Assessment used the reference year 2031 to make effective use of the vehicle fleet emissions forecasts set out by Metro Vancouver, and the Regional Transportation Model. Metro Vancouver’s emission inventory was used. Metro Vancouver conducts an emission inventory, and forecasts emissions, and the latest emission forecasting by Metro Vancouver includes emission forecasts to 2031. Forecasting emissions, and resulting air quality, further into the future will have more uncertainty as projections of what future regulations may be implemented and available vehicle technologies for new vehicles built are unknown. Therefore, 2031 represents a conservative projection of what air quality is expected to be like in the future with and without the Project.</p> | <p>Addressed</p> | <p>None</p> |

| 8.0 ACCIDENTS AND MALFUNCTIONS | | | |
|--|---|---------------|--|
| <p>Adherence to the practices and procedures contained in the Construction Environmental Management Plan will minimize the potential for accidents and malfunctions to occur.</p> <p>In general, replacement of the Tunnel with a new crossing and the proposed highway improvements are expected to lower the risk of accidents and malfunctions during highway operations and maintenance.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations | An Emergency Response and Spill Contingency Plan will outline how construction personnel will prevent, prepare for, respond to, and clean up spills | Addressed | Implementation of mitigation measures outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan) |

| OTHER ISSUES | | | |
|--|---|---------------|--------------------------------|
| Consultation with Squamish Nation identified issues outside of the environmental assessment process, Aboriginal Interests, Aboriginal Consultation, Aboriginal Participation and Project-Related Opportunities, and sections of the Application. | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Increased shipping | The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. | Addressed | None |

APPENDIX M

Stz'uminus First Nation

1.0 Introduction

Stz’uminus First Nation engaged directly with the Ministry on the Project and also collectively with Cowichan Tribes, Halalt First Nation and Penelakut Tribe as member nations of the Cowichan Nation Alliance. The Ministry provided information and funding directly to Stz’uminus. However, Cowichan Nation Alliance provided feedback and participated in meetings and fieldwork. Unless noted otherwise, Cowichan Tribe represented Cowichan Nation Alliance in correspondence, meetings and fieldwork. This overview provides information on consultation with Stz’uminus specifically, and with Cowichan Nation Alliance as applicable to Stz’uminus.

This appendix provides a summary of the information presented in Part C Aboriginal Consultation (Part C) of the Application for an Environmental Assessment Certificate (the Application) regarding the assessment of effects on Aboriginal Interests. Aboriginal Interests are defined as asserted or determined Aboriginal rights, including title, or treaty rights. This appendix presents the information specific to Stz’uminus.

The organization of the information presented generally follows Part C and includes the following sections:

- Consultation;
- Community Profile;
- Existing Conditions;
- Potential Effects;
- Mitigation;
- Residual Effects; and
- Summary and Conclusion.

For more detailed information on the effects assessment on Aboriginal Interests related to Stz’uminus, refer to the following sections of Part C:

- Consultation with Stz’uminus (**Section 10.1.2.10**);
- Stz’uminus community profiles (**Section 10.1.1.11**);
- Description of existing Stz’uminus Aboriginal Interests (**Section 10.1.3.2**);
- Assessment of potential effects of the Project on the exercise of Stz’uminus Aboriginal Interests (**Section 10.1.3.3**);
- Mitigation relating to potential effects on Aboriginal Interests (**Section 10.1.3.4**); and
- Residual effects on Stz’uminus Aboriginal Interests following application mitigation (**Section 10.1.3.5**).

A summary of the Aboriginal Interests Assessment for Stz'uminus is also provided in **Section 10.1.3.8**.

The summary presented in this appendix also incorporated information found in the Stz'uminus Overview Table (**Appendix M2**), which provides detailed information regarding:

- Stz'uminus issues and concerns identified to date;
- Identification of effects on VCs and ICs that relate to the assessment of effects on Stz'uminus' Aboriginal Interests;
- The Ministry's response to specific issues and concerns raised by Stz'uminus;
- The status of these issues and concerns; and
- Next steps required to address outstanding issues and concerns.

2.0 Consultation

This section provides information regarding the consultation activities that the EAO and Ministry carried out prior to submission of the Application.

2.1 EAO-led Consultation Activities

2.1.1 Capacity Funding

When a provincial agency is a proponent of a project going through a provincial EA under the British Columbia *Environmental Assessment Act (BCEAA)*, that agency provides funding to Aboriginal Groups to support their involvement in pre-Application and Application review phases in place of EAO providing such funding. The Ministry's provision of capacity funding is discussed in the following section, Proponent-led Consultation Activities.

2.1.2 Participation in Working Group

EAO invited Stz'uminus and all other Aboriginal groups identified in Schedule B of the Section 11 Order to participate as members of a Working Group.

During the Pre-Application stage, EAO held two Working Group meetings where the Ministry presented information on the Project and the environmental assessment process and received and responded to comments on those presentations. Halalt First Nation represented Cowichan Nation Alliance at the first meeting. Halalt First Nation and Cowichan Tribes represented Cowichan Nation Alliance at the second meeting.

The first Working Group meeting, held January 2016, focused on the environmental assessment process, Project overview and update, Key Areas of Study, draft Application Information Requirements overview, and preliminary conclusions from study results.

The second working group meeting, held March 2016, focused on the environmental assessment process, list of materials available on the Project website, review of comments received on, and resulting changes to, the draft Application Information Requirements, and a description and rationale of the assessment areas. Working Group comments raised by Cowichan Nation Alliance in relation to the draft Application Information Requirements resulted in Aboriginal groups being invited to participate in river-otter related fieldwork in April 2016. The objectives of this work were to document river otter presence or potential presence within the Regional Assessment Area, document and describe use of riparian and high use areas and identify potential Project-related effects.

Cowichan Nation Alliance participated in the completeness review of the Application for an Environmental Assessment Certificate (Application) that considered whether the Application included information requirements set out in the Application Information Requirements.

It is anticipated that Stz’uminus will continue as an active member of the Working Group through the environmental assessment process.

2.2 Proponent-led Consultation Activities

The Ministry began consultation with Stz’uminus in early 2014 in order to identify the nature and scope of Stz’uminus’ Aboriginal Interests and how they might be impacted by the Project. Following is a summary of consultation activities led by the Ministry with Stz’uminus. A more detailed discussion is provided under the Stz’uminus section in **Section 10.1.2.10 Overview of Consultation with each Schedule B Aboriginal Group**. The following sections represent the main activities undertaken in support of Proponent-led consultation and include the following:

- Provision of capacity funding;
- Traditional use, traditional knowledge and other studies;
- Examples of Consultation Activities; and
- Concerns Identified to Date.

2.2.1 Capacity Funding

The Ministry entered into a Participation Funding Agreement, including the Initial Consultation and Pre-Application phases for consultation, with Stz’uminus. The Ministry has been working with Stz’uminus regarding their needs for capacity funding to facilitate their participation in the Application Review Phase. Consultation activities that are anticipated to be undertaken during the Application Review phase that will be supported by capacity funding include participation in technical reviews and analyses, involvement in ongoing consultation activities, and presentation of key information regarding their respective Aboriginal Interests.

2.2.2 Traditional Use, Traditional Knowledge & Other Studies

- The Ministry provided additional funding to Stz’uminus for the preparation and submission of Traditional Use, Traditional Knowledge or other studies. Stz’uminus worked with other Cowichan Nation Alliance members and submitted the following traditional use studies: *Cowichan Nation Traditional, Current, and Planned Future Use of the George Massey Tunnel Replacement Bridge Project Area, prepared by Candace Charlie for Cowichan Tribes, on behalf of the Cowichan Nation Alliance, August 9, 2015*
- *George Massey Tunnel Replacement Project: Cowichan Occupation and Use of the Project Lands, prepared by Dorothy Kennedy for David Robbins of Woodward and Co., Counsel for the Cowichan Tribes, on behalf of the Cowichan Tribes, August 25, 2015*

Cowichan Nation Alliance also provided to the Ministry: *Historical Geography of Cowichan Land Use and Occupancy Lower Fraser River: Map Series and Report, prepared for Woodward and Company and the Cowichan Tribes by Kenneth G. Brealey, May 31, 2010.*

The purpose of such studies is to identify Aboriginal input and traditional knowledge for inclusion and consideration in the EA. In addition, studies were funded to enhance the Ministry’s understanding of Aboriginal Interests and Aboriginal Group’s past, present and desired future use as it pertains to the exercise of Aboriginal Interests within the Project area and the potential adverse effects on identified Aboriginal Interests.

2.2.3 Examples of Consultation Activities

A number of consultation activities were undertaken with Stz’uminus during both the Initial Consultation Phase and the Pre-Application Consultation Phase as follows:

Initial Consultation Phase Activities - The Ministry recognized the importance and value of early engagement with Schedule B Aboriginal Groups and undertook an Initial Consultation Phase prior to the Pre-Application Phase. The Initial Consultation Phase concluded in December 16, 2015 with submission of the Project Description and Key Areas of Study document. The focus of

the Initial Consultation Phase was collection of baseline information and sharing of draft EA-related documents (i.e. Project Description and Key Areas of Study, Application Information Requirements (AIR)). The main consultation activities the Ministry undertook with Stz’uminus included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Stz’uminus;
- Funding for Stz’uminus’ participation in Project consultation activities and EA process;
- Stz’uminus participation in field studies;
- Site visit;
- Review of draft EA documents such as the Project Description and Key Areas of Study, Heritage Resources Overview Assessment/Archaeological Overview Assessment, AIR, Heritage Resources Assessment and Aboriginal Consultation Plan;
- Meetings with Stz’uminus Chief and Council, staff, consultants, and elders; and
- Response and follow up with Stz’uminus regarding the identification and resolution of issues.

Pre-Application Consultation Phase Activities - The Pre-Application Consultation Phase began with the filing of the Project Description and Key Areas of Study document on December 16, 2015 and concluded with the submission of the Application. This phase included the issuance of the Section 11 Order, AIR development and collection of baseline information (may include submission of permit applications). The main consultation activities the Ministry undertook with Stz’uminus included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Stz’uminus;
- Funding for Stz’uminus’ participation in Project consultation activities and EA process;
- Meetings with Stz’uminus Chief and Council, staff, consultants, elders and membership and Cowichan Nation Alliance;
- Stz’uminus participation in fieldwork;
- Stz’uminus participation in the EA Working Group;
- Review of draft EA documents such as the Application Information Requirements, Aboriginal Consultation Plan, and Aboriginal Consultation Reports; and
- Response and follow up with Stz’uminus regarding the identification and resolution of issues.

2.2.4 Concerns Identified to Date

As outlined above, Stz’uminus’ concerns, identified through consultation undertaken to-date, are presented in **Appendix M2 Stz’uminus Overview Table**. The Ministry’s response to Stz’uminus’ key concerns regarding potential impacts on Stz’uminus’ Aboriginal Interests are outlined below:

Table 1 Concerns Identified to Date

| Concerns Identified to Date | Response |
|--|--|
| <p>Potential impacts to Cowichan Nation Alliance title, Rights and culture.</p> | <p>Potential Project related impacts to Stz’uminus title, Rights and culture, the level of effect predicted, and mitigation measures are outlined the Application. The Ministry will continue to consult with Cowichan Nation Alliance to ensure any effects are minimized.</p> |
| <p>Aboriginal participation and Project-related opportunities</p> <ul style="list-style-type: none"> • Potential employment, training, contracting and economic development opportunities • Community preparedness • Cultural recognition and naming • Revenue sharing opportunities from tolling • Re-establishment of a site on ʔəqtinəs/Tl’uqtinus site for residential and/or commercial purposes • Surplus land | <p>The Ministry is committed to working with Stz’uminus to identify potential employment, training, contracting and economic development opportunities and to identify ways to support community preparedness.</p> <p>The Ministry is exploring opportunities for cultural recognition and naming and will work with Stz’uminus on these opportunities.</p> <p>The provincial tolling strategy stipulates that revenue from tolling may only be used to defray the costs of designing, constructing, operating and maintaining highways.</p> <p>The Ministry notes Cowichan Nation Alliance’s wish to re-establish a site on ʔəqtinəs/Tl’uqtinus site for residential and/or commercial purposes.</p> <p>As part of the Project, agricultural land will be protected as much as practical. Once the project is completed, there will be a determination of surplus lands, if any, and disposition will follow the appropriate process including consultation</p> |

| Concerns Identified to Date | Response |
|---|---|
| <p>Effects to fish and fish habitat</p> <ul style="list-style-type: none"> • Importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon • Potential effects of pile driving, blasting and underwater noise generated by Tunnel decommissioning and other construction activities | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon, salmon to Stz’uminus and is committed to avoiding or mitigating any potential effects.</p> <p>The Ministry designed a clear span bridge over the Fraser River South Arm and Deas Slough to avoid or minimize Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat.</p> <p>As outlined in Section 4.3 (Underwater Noise), sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources will be effectively mitigated by scheduling activities during period of low tide, when work can be completed under shallow water conditions or in the dry.</p> |
| <p>Environmental Assessment (EA):</p> <ul style="list-style-type: none"> • Adequacy of methodology to address social and cultural effects • Process and associated timelines • Strength of Claim Assessment | <p>The Ministry acknowledges the importance of Stz’uminus’s involvement in the environmental assessment process and is committed to funding Stz’uminus’s participation in the Initiation Consultation and Application Review phases.</p> <p>Stz’uminus’s concerns related to Environmental Assessment including the adequacy of methodology to address social and cultural effects, process and associated timelines are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> <p>Concerns relating to the Strength of Claim Assessment have been referred to EAO.</p> |

| Concerns Identified to Date | Response |
|---|---|
| <p>Social effects of the Project on Cowichan Nation Alliance’s ability to transfer knowledge, language and participate in socio-cultural practices</p> | <p>Social effects of the Project on Stz’uminus’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of Part C of the Application.</p> |
| <p>Cumulative effects:</p> <ul style="list-style-type: none"> • Consideration of cumulative effects on Aboriginal rights • Absence of comprehensive study on cumulative effects on the Fraser River | <p>The Application includes historical context relating to changes in use over time by Stz’uminus and other Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by Stz’uminus or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests.</p> <p>While the Ministry acknowledges that Stz’uminus is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project.</p> |
| <p>Concerns related to dredging, potential for increased vessel traffic and larger vessels resulting from Tunnel decommissioning</p> | <p>Dredging to deepen the river is not a component of this Project and the Ministry is unaware of any plans by others to dredge the river deeper. The Project, including the decommissioning of the Tunnel, will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. This is outlined in Sections 1.1.7.2 (Construction), 4.1 (River Hydraulics) and 4.2 (Water Quality and Sediment) of the Application.</p> |

| Concerns Identified to Date | Response |
|---|---|
| Potential effects on Fraser River flow rates after Tunnel removal | Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Flow rates are discussed in Section 4.1 (River Hydraulics). |
| Potential effects of run off and drainage | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected.</p> <p>Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> |

3.0 Community Profile: Stz’uminus First Nation

Stz’uminus is governed by a chief and council, but under a custom electoral system, with the current three-year term for the ten-member council expiring in April 2017.

While the First Nations affiliated with the Cowichan Nation Alliance have explained that they traditionally resided on both sides of the Strait of Georgia as part of a seasonal round, Stz’uminus’ main present-day community is located in Ladysmith on southeast Vancouver Island. Of 1,296 registered members, 712 live on reserve. The Project area does not overlap any of Stz’uminus’ current or former reserve lands.

Stz’uminus is, or has been, affiliated with the Hul’qumi’num Treaty Group, along with the other three Cowichan Nation Alliance members, Lake Cowichan First Nation and Lyackson First Nation. These First Nations have been described as speakers of the “Island” dialect of Halkomelem (*Hul’q’umi’num*), and have referred to themselves collectively as *Hul’qumi’num Mustimuhw*.

The Hul’qumi’num Treaty Group member bands collectively assert a core territory or “title lands” and a wider marine or fishing territory, as described in its Statement of Intent to the British Columbia Treaty Commission. Core areas over which title is asserted include but are not limited to “the south arm of the Fraser River, including Canoe Pass, up to and including Douglas Island, with lands on the north shore of the south arm up to Sapperton Channel (New Westminster), the islands in the south arm of the Fraser River and the south bank of the Fraser River along Canoe Pass up to Deas Island”. This area is subsumed within the broader marine or fishing territory. The core territory of the Hul’qumi’num Treaty Group overlaps the Project area at the Tunnel crossing.

Stz’uminus, along with each of the other Cowichan Nation Alliance member First Nations, has a Forest Consultation and Revenue Sharing Agreement with the Province of British Columbia. In the map for the Stz’uminus’ 2013 agreement, the territory depicted is equivalent to the collective core territory of the Hul’qumi’num Treaty Group.

Locations along the South Arm of the Fraser River of importance to Stz’uminus, along with the Cowichan Nation Alliance member First Nations, in the vicinity of the Project include but are not limited to *Tl’uqtinus*, spanning the north shore from opposite Deas Island to opposite Tilbury Island, and *Hwlhits’um* or *Xwulit’sum*, on Canoe Pass. Both of these areas are considered by Cowichan Nation Alliance member bands as ancestral village and resource sites. A member First Nation of the organization has previously reported that the Cowichan Nation Alliance is working to re-establish a permanent land base at *Tl’uqtinus* for residential and/or commercial purposes. Cowichan Nation Alliance’s *Tl’uqtinus* claim area is shown in **Section 10.1.3.2**

Existing Conditions.

3.1 Stz’uminus First Nation Aboriginal Interests: Existing Conditions

This section provides a high level of summary of past, present, and desired future use of the proposed Project area and surroundings for traditional purposes that are or may be connected with the exercise of Stz’uminus’ Aboriginal Interests. A more detailed discussion, including sources used, is provided under Stz’uminus First Nation in **Section 10.1.3.2 Existing Conditions**.

3.1.1 General

- Stz’uminus has Aboriginal Interests that are known to overlap or lie in the vicinity of the Project corridor, which includes a portion of the South Arm of the Fraser River.
- Stz’uminus followed a seasonal round of resource use and regional settlement that took them from their winter residences on Vancouver Island and the Gulf Islands across the Strait of Georgia to the Fraser River estuary, where they resided for all or part of the annual salmon runs (April to through October), or, in some instances, year-round. The seasonal round is described in Part C.
- Stz’uminus has identified past and ongoing effects that have altered and reduced use over time, constraining the current exercise of their Aboriginal Interests.
- A Cowichan Nation Alliance member First Nation has previously reported that the Cowichan Nation Alliance is working to re-establish a permanent land base at *Tl’uq̓tinus* for residential and/or commercial purposes.

3.1.2 Fishing

- Stz’uminus harvested the following species historically on the South Arm of the Fraser River: sockeye and pink salmon, sturgeon, shellfish, and marine mammals. Cowichan Nation Alliance has previously reported that now filled-in sloughs and streams in or near Highway 99 once supported coho and eulachon, which were also harvested while they were resident on the Fraser River.
- Cowichan Nation Alliance reports that *Tl’uq̓tinus* was used seasonally for harvesting purposes, with Halalt reporting that they used the area specifically in July to fish for sockeye and pink salmon. Stz’uminus also used other habitation sites in the area, including one at Steveston.
- Areas within the wider Fraser River estuary were also utilized by *Hul’q’umi’num’*-speaking peoples for fishing salmon, sturgeon, groundfish, and other marine resources on the foreshore (e.g., Tsawwassen, Point Roberts, Boundary Bay). Certain species (e.g., sockeye and pink salmon, sturgeon, eulachon, trout, flounder) could only be obtained in, or were preferred to be taken at, Fraser River-based locations.

- The Hul’qumi’num Treaty Group have reported that during the reserve creation era in the late nineteenth century, government officials were aware of *Hul’qumi’num Mustimuhw* fishing interests at the Fraser River; however, no reserves were set aside for them in the area. The Hul’qumi’num Treaty Group have also reported that government regulations introduced in the same era had the effect of restricting their access to fishing in the Fraser River. Despite these changes, *Hul’qumi’num Mustimuhw* say they continued to use the Fraser River for fishing, including commercially, into the early twentieth century.
- Member First Nations of the Cowichan Nation Alliance have been attempting to restore former fisheries within the Fraser River through Fisheries and Oceans Canada (DFO). Access to sockeye for member First Nations is said to be provided by DFO annually in Johnstone Strait and “off the mouth of the Fraser River”. In the vicinity of the Project area, however, access has been subject to negotiations with First Nations local to the lower Fraser River, and has been limited, occurring only in 2005, 2006, and 2008. In those years, the specific locations in the South Arm in which member First Nations of the Hul’qumi’num Treaty Group fished for food, social, and ceremonial (FSC) purposes under communal licences was below the Port Mann Bridge generally, as well as specifically, on some occasions, below the easterly point of Kirkland Island (i.e., downstream of the Project area). The Cowichan Nation Alliance has stated that it is in ongoing, active litigation over its asserted fishing rights on the South Arm of the Fraser River.
- The Hul’qumi’num Fisheries Limited Partnership (HFLP) is a commercial fishing business in which some of the Cowichan Nation Alliance member groups participate (Halalt, Penelakut, and Stz’uminus). Species harvested through this enterprise are crab, prawn, halibut, herring, rockfish, sablefish, and salmon.

3.1.3 Hunting/Trapping

- Cowichan Nation Alliance has previously reported that Highway 99 was built on what was once a prime harvesting location for deer, ducks, and geese, among other species.
- Canada goose, northern shoveler, and green-winged teal would have been available to the Cowichan people year-round.
- The south shore of Lulu Island, along the South Arm of the Fraser River, has been reported as a prime spot for trapping beaver, mink, and muskrat; bear, grouse, elk, squirrel, and porcupine were also hunted by the Cowichan people on the South Arm. The Cowichan Nation Alliance as a group has stated a desire to resume the harvest of traditional resources in the Project area.
- Cowichan Nation Alliance has also stated that its members revere bald eagles, which were not hunted. Their Elders have indicated that eagle numbers in the Richmond area have been dwindling each year. Breeding habitat along the Highway 99 corridor on Lulu Island has been previously noted.

3.1.4 Gathering

- Cowichan Nation Alliance report that in the marshy areas south of Canoe Passage near Brunswick Point – in the area of *Xwulits’um*, or place for cutting (cattails) – as well as in the area of *Tl’uqtinus* and across the Fraser River on Tilbury Island, several varieties of cattails and rushes (*stth’equn*) were once harvested.
- Berries and other plants were gathered and cultivated by the ancestors of the Cowichan Nation Alliance member bands at *Tl’uqtinus*, and were harvested from other locations in the Project area. These plants included wild rose, rose hips, crabapples, elderberries, horsetail, labrador tea, Indian hemp, trembling aspen, mock orange, oregon grape, maple leaves, cranberries, blueberries, blackberries, wapato, bulrushes/reeds (*stth’equn*), as well as seaweed. With respect to berry plants at *Tl’uqtinus* specifically, a 1979 map produced by Environment Canada noted an “Indian residence” at this location, accompanied by the caption (not attributed to any specific Aboriginal group): “It is known that the Indians who lived here for several thousand years harvested berries from the bogs and used fire to maintain open areas for the berry bushes by preventing encroachment from pine trees”.
- Cowichan Nation Alliance has indicated that they wish to see existing bogs on Lulu Island near the Highway 99 corridor – specifically, one near Williams Road (which runs perpendicular to Highway 99) and another near the Richmond Nature Park (bisected by Highway 99 at Westminster Highway) – protected to support future use of traditional resources, like berries and other bog ecosystem flora. At *Tl’uqtinus*, which is currently surrounded by blueberry farms, Cowichan Nation Alliance has raised the potential for their former berry grounds to be re-established.

3.1.5 Archaeology and Cultural Heritage Interests

- Locations along the South Arm of the Fraser River of importance to the Cowichan Nation Alliance in the vicinity of the Project include, but are not limited to, *Tl’uqtinus*, spanning the north shore from opposite Deas Island to opposite Tilbury Island, and *Hwlhits’um* or *Xwulit’sum*, on Canoe Pass. Both of these areas are considered by Cowichan Nation Alliance member bands as ancestral village and resource sites.
- Cowichan Nation Alliance has specifically noted the importance of archaeological site DgRs-17.

3.1.6 Other Related Interests

- Cowichan Nation Alliance has stated that it asserts Aboriginal title to *Tl’uqtinus*, and given where *Tl’uqtinus* is reportedly situated, to the Project footprint. The Cowichan Nation Alliance has expressed its view that this title includes the right to manage the land, determine the uses to which it can be put, and obtain any economic benefits from it. Cowichan Nation Alliance has advised that it is also working to re-establish culturally

integral practices (e.g., harvesting fish, waterfowl, plants) on the South Arm and at the mouth of the Fraser River, including at and about *Tl’uq̓tinus*.

- The Cowichan Nation Alliance has previously reported that for the last generation its member First Nations have been rejuvenating their access to the waterways that once served as the highways for their ancestors, working with the currents and tides to travel for FSC purposes. The Cowichan Nation Alliance has expressed concern regarding the contaminants and the sustainability of vital habitats that are necessary to support their members.

4.0 Potential Effects

This section provides a summary of the methodology used to identify potential adverse effects of the proposed Project on the exercise of Aboriginal Interests by Aboriginal Groups during Project construction and operation, followed by a summary of potential effects on Stz’uminus’ Aboriginal Interests, specifically. For a more detailed description, refer to **Section 10.1.3.3.**

Potential Effects.

4.1 Methodology for Identification of Potential Effects

The first step in the effects assessment on Aboriginal interests was the identification of potential adverse effects on traditional use activities and related interests as a result of Project construction or operation. To evaluate these potential adverse effects, the findings of the following Valued Component (VC) chapters in Part B of the Application were considered, including identified mitigation measures, residual effects, cumulative effects and follow up strategies:

- **Section 4.4 Fish and Fish Habitat**
- **Section 4.6 Marine Mammals**
- **Section 4.7 Vegetation**
- **Section 4.8 Terrestrial Wildlife**
- **Section 5.2 Marine Use**
- **Section 5.3 Land Use**
- **Section 5.5 Visual Quality**
- **Section 6.1 Heritage Resources**
- **Section 7.1 Human Health**

The findings of the following Intermediate Component (IC) chapters were also considered in the assessment:

- **Section 4.1 River Hydraulics and River Morphology**
- **Section 4.2 Sediment and Water Quality**

- **Section 4.9 Air Quality**
- **Section 4.10 Atmospheric Noise**

The assessment of potential adverse effects of the Project on the exercise of Aboriginal Interests, including measures to address those effects, are presented in **Section 10.1.3.3** through **Section 10.1.3.5**, and largely applies the same methods used in Part B of the Application for the IC and VC assessments, as outlined in **Section 3.0 Assessment Methodology**.

In addition to information from the VC and IC assessments that support the assessment of potential effects on Aboriginal Interests, information from a Health Impact Assessment (HIA) undertaken to support Project planning, including mitigation recommendations, has been integrated into the assessment of potential effects on Aboriginal Interests. The HIA for the Project can be found at <https://engage.gov.bc.ca/masseytunnel>. A summary of the key findings is provided in **Section 7.2 Health Impact Assessment**.

4.2 Selection of Indicators

Four parameters were chosen as indicators to understand and evaluate potential Project-related effects on the exercise of Aboriginal Interests. The rationale for their selection is presented in the following table.

Table 2 Indicators for the Aboriginal Interests Assessment

| Indicator | Rationale for Selection |
|--|---|
| Access to preferred locations for the exercise of Aboriginal Interests | Project components or activities could result in changes in access to or patterns of travel between traditional use locations on land or water |
| Availability of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in distribution or movement, relative abundance, or habitat area or composition of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in the real or perceived quality of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in |

| Indicator | Rationale for Selection |
|---|---|
| | public sources specific to the exercise of their Aboriginal Interests) |
| Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests | Project components or activities could result in: (1) direct sensory disturbance to traditional users (e.g., from noise, vibration); and/or (2) indirect changes to cultural practices, customs or traditions – i.e., cultural heritage or the expression and transfer of cultural values or ways of knowing (e.g., language, laws/governance, stories, spiritual beliefs) – tied to the cultural landscape or to the traditional use of specific traditional use locations or resources within that landscape. |

Potential adverse effects on the indicators noted above were analyzed in terms of the type and level of effect that Project components and activities may be expected to have on the exercise of Aboriginal Interests.

For the purposes of this assessment, no effect was understood to mean that no interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests would be expected. Where it was determined that an interaction, and potential effect, could occur, the following definitions were used to guide the characterization of the effect as negligible or measurable:

- Negligible – An interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests may occur, but modifications to the use of preferred options would not be expected.
- Measurable – Modifications to the exercise of Aboriginal Interests at preferred locations or in relation to preferred resources may be needed, and may be considered to be:
 - Minor (minimal or temporary modifications may be required to use preferred options),
 - Moderate (more frequent or longer term modifications may be required to use preferred options), or
 - Serious (permanent or indefinite modifications may be required potentially resulting in the loss of preferred options).

4.3 Identified Potential Effects

As noted above, the first step in evaluating potential adverse effects on Aboriginal Interests was a consideration of the findings for relevant Part B VCs, including identified mitigation measures, residual effects, cumulative effects and follow up strategies. The residual effects with the potential to result in an adverse effect on Aboriginal Interests are then carried forward in the assessment. Using the four indicators noted in the previous section, the potential Project-

related effects and level of effect predicted in relation to Stz’uminus’ exercise of Aboriginal Interests remaining after Part B mitigation are as follows:

Table 3 Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|---|--------------|------------|------------|------------|----------------------------|
| | Negligible | Measurable | Negligible | Measurable | |
| River locations for traditional use as a result of changes to physical characteristics of these locations | ✓ | | ✓ | | |
| Instream locations for traditional use | ✓ | | ✓ | | |
| Upland locations for traditional use | ✓ | | ✓ | | |

4.4 Potential Project-Related Effects on Stz’uminus’ Aboriginal Interests

Using the methodology presented in **Section 10.1.3.3 Potential Effects**, Table 7 provides the potential incremental Project-related effects, following mitigation of Project-related effects on Part B VCs and ICs as described in Part B, related to Stz’uminus’ Aboriginal Interests as summarized in Existing Conditions were identified for Project Construction and Operation. A discussion of potential Project-related effects on fishing, hunting/trapping, gathering and archaeology and cultural heritage follows the table.

Table 7 Summary of Potential Project-Related Effects

| Indicator | Potential Project-Related Effect |
|--|---|
| Project Construction | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • Potential temporary direct (minor) effect on quality of experience related to construction-related noise • Potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance |
| Project Operation | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |

| Indicator | Potential Project-Related Effect |
|--|---|
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • Potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses • Potential permanent direct (minor) effect on quality of experience related to traffic noise • Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses |

4.5 Fishing

Stz’uminus harvested the following s historically on the South Arm of the Fraser River included sockeye and pink salmon, sturgeon, shellfish, and marine mammals. Cowichan Nation Alliance has previously reported that now filled-in sloughs and streams in or near Highway 99 once supported coho and eulachon, which were also harvested while resident on the Fraser River. Certain species (e.g., sockeye and pink salmon, sturgeon, eulachon, trout, flounder) could only be obtained in, or were preferred to be taken at, Fraser River-based locations. Member First Nations of the Cowichan Nation Alliance have been attempting to restore former fisheries within the Fraser River through Fisheries and Oceans Canada (DFO).

The proposed Project has the potential to affect fishing practices through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred fishing locations by Stz’uminus, as a result of changes in river hydraulics or morphology, are expected to be negligible before mitigation. Potential changes in access to instream locations for fishing by Stz’uminus during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to fishing locations by Stz’uminus from instream construction activities are expected to be negligible. While it is acknowledged that Cowichan Nation Alliance has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Mitigation measures identified in the fish and fish habitat assessment to address Project-related effects on fish are expected to be effective at addressing potential effects on the availability of fishing resources preferred by Stz’uminus. Further, as residual effects on fish identified in the fish and fish habitat assessment are not anticipated to affect population integrity, potential residual effects as a result of Project construction activities, would not be expected to measurably affect the availability of preferred fish resources.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of fishing resources preferred by Stz’uminus; therefore, Potential Project-related effects on Stz’uminus fishing would be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when fishing are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in in Section 4.10 Atmospheric Noise are expected to largely address a potential Project-related effect to the quality of experience while fishing. At preferred fishing locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Stz’uminus.

Section 5.5 Visual Quality predicts that residual effects to visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Stz’uminus is fishing. As this landscape has been previously modified, the potential Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Stz’uminus’ Aboriginal Interests related to fishing are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.6 Hunting/Trapping

Stz’uminus reported that Highway 99 was built on what was once a prime harvesting location for deer, ducks, and geese, among other species. Along the Fraser River, including Canoe Pass, as well as elsewhere in their collective territory, brant goose, canvasback duck, common merganser, and mallard have been specifically identified as harvested species by Cowichan Tribes, and that this harvesting would have taken place in the fall. Canada goose, northern shoveler, and green-winged teal would have been available to the Cowichan people year-round. The south shore of Lulu Island, along the South Arm of the Fraser River, has been reported as a prime spot for trapping beaver, mink, and muskrat; bear, grouse, elk, squirrel, and porcupine were also hunted by the Cowichan people on the South Arm.

The proposed Project has the potential to affect hunting and trapping through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred hunting and trapping locations by Stz’uminus as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for hunting and trapping by Stz’uminus during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to hunting and trapping locations by Stz’uminus from instream construction activities, are expected to be negligible. While it is acknowledged that Cowichan Nation Alliance has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for hunting and trapping by Stz’uminus resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with hunting and trapping locations.

Mitigation measures identified in the marine mammal and terrestrial wildlife assessments are expected to be effective at addressing potential effects on the availability of hunting and trapping resources preferred by Stz’uminus. Therefore, Project-related effects on hunting and trapping related to potential changes in the availability of resources would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for hunting and trapping by Stz’uminus; therefore, Potential Project-related effects on Stz’uminus fishing would be expected to be negligible.

Project operation is not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when hunting and trapping are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** to address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while hunting and trapping. At preferred hunting and trapping locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Stz’uminus.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Stz’uminus is hunting and trapping. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Stz’uminus’ Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.7 Gathering

Cowichan Nation Alliance report that in the marshy areas south of Canoe Passage near Brunswick Point – in the area of *Xwulits’um*, or place for cutting (cattails) – as well as in the area of *Tl’uqtinus* and across the Fraser River on Tilbury Island, several varieties of cattails and rushes (*stth’equn*) were once harvested. Berries and other plants were gathered and cultivated by the ancestors of the Cowichan Nation Alliance member bands at *Tl’uqtinus*, and were harvested from other locations in the Project area. These plants included wild rose, rose hips, crabapples, elderberries, horsetail, labrador tea, Indian hemp, trembling aspen, mock orange, oregon grape, maple leaves, cranberries, blueberries, blackberries, wapato, bulrushes/reeds (*stth’equn*), as well as seaweed. Tree species available in the vicinity of the Fraser River and traditionally used by the Cowichan Tribes for manufacturing include crabapple, willow, alder, cottonwood, cedar, spruce, aspen, yew, hemlock, and vine maple.

The proposed Project has the potential to affect gathering through changes in access to preferred locations, changes in availability of preferred resources, changes in quality of preferred resources and changes in quality of experience when gathering.

Potential changes in access to preferred gathering locations by Stz’uminus as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for gathering by Stz’uminus during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to gathering locations by Stz’uminus from instream construction activities, are expected to be negligible. While it is acknowledged that Cowichan Nation Alliance has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for gathering by Stz’uminus resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with gathering locations.

Mitigation measures identified in the vegetation assessment to address Project-related effects on terrestrial vegetation are expected to be effective at addressing potential effects on the availability of resources for the exercise of Aboriginal Interests related to gathering. Therefore, Project-related effects on gathering related to potential changes in the availability of vegetation would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for gathering by Stz’uminus; therefore, Potential Project-related effects on gathering related to potential changes in the quality of resources would therefore be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when gathering are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while gathering. At preferred gathering locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Stz’uminus.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Stz’uminus is gathering. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Stz’uminus’ Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.8 Archaeology and Cultural Heritage Interests

Locations along the South Arm of the Fraser River of importance to the Stz’uminus in the vicinity of the Project include, but are not limited to, *Tl’uqtinus*, spanning the north shore from opposite Deas Island to opposite Tilbury Island, and *Hwlhitsu’um* or *Xwulit’sum*, on Canoe Pass. Both of these areas are considered by Cowichan Nation Alliance member bands as ancestral village and resource sites.

The proposed Project has the potential to affect Stz’uminus’s Aboriginal Interests related to archaeology and cultural heritage through changes in access to preferred locations and changes in quality of experience.

Potential changes in access to locations related to Stz’uminus’s archaeological and cultural heritage interests as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations related to Stz’uminus’s interests related to archaeology and cultural heritage during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to locations related to Stz’uminus’s archaeological and cultural heritage interests from instream construction activities are expected to be negligible. While it is acknowledged that Cowichan Nation Alliance has reported a desire for higher levels of use in

this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations related to Stz’uminus’s archaeological and cultural heritage interests resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and not expected to overlap with locations related to Stz’uminus’s archaeological and cultural heritage interests.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** would also be expected to address the potential Project-related effect to the quality of experience while undertaking activities related to cultural heritage. At locations related to Stz’uminus’s archaeological and cultural heritage interests that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Stz’uminus.

As reported in **Section 6.1 Heritage Resources**, no archaeological or historical sites were identified within the Project area during fieldwork; however, there may be other locations with intangible cultural value or meaning to Stz’uminus (e.g., spiritual or storied sites, named places) potentially affected by the Project. In addition, physical alterations to the landscape may affect archaeological or historical sites, and how this landscape is experienced culturally.

As a result, mitigation measures proposed in Part B are not expected to address a potential incremental and permanent Project-related effect tied to Stz’uminus’s Aboriginal Interests related to archaeology and cultural heritage that may be associated with the introduction of a new prominent feature to the cultural landscape. As this landscape has been previously modified by anthropogenic changes, the potential incremental Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal, but permanently disruptive for Stz’uminus, who have identified a historical connection to, and continued or desired use of, sites or places that help define the cultural landscape in the Project area.

Additional mitigation to address this potential incremental effect that is not otherwise addressed in the Application is proposed in **Section 10.1.3.4** and summarized below under Mitigation.

5.0 Mitigation

This section provides a summary of mitigation measures identified to address potential Project-related effects on the exercise of Aboriginal Interests by Stz’uminus. For a more detailed discussion, refer to **Section 10.1.3.4 Mitigation**.

Mitigation measures identified for the relevant VCs and ICs in Part B of the Application were reviewed to assess their effectiveness at addressing potential Project-related effects on the exercise of Aboriginal Interests related to those VCs. Examples of mitigation that are proposed in the Application to address potential effects on VCs and ICs, with the potential to result in an effect on Aboriginal Interests, include:

- Avoiding fisheries sensitive timing windows during key Project activities.
- Developing a Marine Access Management Plan to ensure marine use activities, including those supporting Aboriginal Interests, can continue during Project construction.
- Scheduling activities with the potential to generate underwater noise to avoid potential effects on marine mammals.
- Development and implementation of a Terrestrial Vegetation and Wildlife Management Plan with measures to minimize disturbance and loss of vegetation, prevent soil compaction, and minimize clearing in order to minimize effects on vegetation.

These measures are expected to be largely effective at avoiding, reducing, or otherwise managing potential Project-related effects on the exercise of Aboriginal Interests during Project construction and operation.

Recognizing some measurable effects on Stz’uminus’s Aboriginal Interests could remain following the application of mitigation to address potential effects on the relevant VCs and ICs in Part B, the following additional measures have been identified to address such effects:

- Ongoing consultation with Stz’uminus regarding proposed measures, management plans, and monitoring programs related to intermediate components and valued components assessments; and
- Development of a Cultural Heritage Management Plan.

6.0 Residual Effects

With the implementation of mitigation measures identified in Section 10.1.3.4 and summarized above, residual adverse effects of the proposed Project on the exercise of Aboriginal Interests are expected to be negligible (i.e., not measurable or detectable), and are not further assessed.

7.0 Summary and Conclusion

Part C of the Application builds on consultation undertaken to date to understand Stz’uminus’s Aboriginal Interests and provides for an assessment of potential Project-related effects of the Project on Aboriginal Interests.

The Ministry began consultations with Stz’uminus prior to the submission of the Project Description, which is the end of the Initial Consultation Phase. Both EAO and the Ministry consulted with Stz’uminus during the Pre-Application Phase, which concluded with the submission of the Application. The main concerns expressed by Stz’uminus during consultations include:

- Potential impacts to Stz’uminus title, rights and culture;
- Consideration for future uses should include Stz’uminus’s plans;
- Aboriginal participation and Project-related opportunities (e.g., potential employment, training, contracting and economic development opportunities);
- Potential effects to air quality, particularly in relation to terrestrial wildlife;
- Effects to fish and fish habitat, and importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon;
- Potential effects of pile driving, blasting and underwater noise generated by Tunnel decommissioning and other construction activities;
- Adequacy of EA methodology to address social and cultural effects;
- EA process and associated timelines;
- Strength of claim;
- Social effects of the Project on Stz’uminus’s ability to transfer knowledge, language and participate in socio-cultural practices;
- Cumulative effects;
- Concerns related to dredging, potential for increased vessel traffic and larger vessels resulting from Tunnel decommissioning;
- Potential effects on Fraser River flow rates after Tunnel removal; and
- Potential effects of run off and drainage.

Based on information provided by Stz’uminus and other publicly-available sources, the Ministry developed a summary of past, present and desired future use of the proposed Project area and its surroundings for the purposes of fishing, hunting/trapping, gathering, archaeology and cultural heritage interests and other related interests. This summary indicates that Stz’uminus has, does and intends to continue to use the Fraser River for cultural purposes.

Relying first on the results of the effects assessments for related VCs and ICs in Part B, the assessment of potential effects of Stz’uminus’s Aboriginal Interests considered four indicators:

1. Access to preferred locations for the exercise of Aboriginal Interests;
2. Availability of preferred resources for the exercise of Aboriginal Interests;
3. Quality of preferred resources for the exercise of Aboriginal Interests; and
4. Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests.

As reviewed in **Section 10.1.3.3** and **Section 10.1.3.4**, the mitigation measures, management plans, and monitoring programs identified in Part B of the Application for ICs or VCs linked to the exercise of Aboriginal Interests are expected to be largely effective at addressing the incremental Project-related effects noted above on the exercise of Aboriginal Interests by Stz’uminus, except in the following potentially measurable cases:

- Project construction:
 - Potential temporary direct (minor) effect on quality of experience related to construction-related noise and a potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance
- Project operation:
 - Potential permanent direct (minor) effect on quality of experience related to traffic noise and a potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses
 - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses.

The following additional measures have been identified to address the above-noted effects:

- Ongoing consultation with Stz’uminus regarding proposed measures, management plans, and monitoring programs related to VC and IC assessments; and
- Development of a Cultural Heritage Management Plan.

With the implementation of mitigation proposed to address potential effects on VCs and ICs, as well as additional mitigation proposed to address potential residual effects on Aboriginal Interests, no effects on the exercise of Aboriginal Interests by Stz’uminus, as a result of the Project, are expected.

ENVIRONMENTAL ASSESSMENT PROCESS

An environmental assessment of the Project is required under the B.C. Environmental Assessment Act (B.C. EAA), S.B.C. 2002, c. 43, and permits to construct and operate can only be received once the environmental assessment process is complete and an Environmental Assessment Certificate (EAC) has been issued. If the Project is approved, an EAC will be awarded to and held by the Ministry. The Reviewable Projects Regulation B.C. Reg. 370/2002 under the B.C. EAA sets out the criteria for reviewable projects.

On December 16, 2015, the B.C. Environmental Assessment Office (EAO) issued a Section 10(1)(c) Order confirming that the Project is a reviewable project pursuant to the B.C. EAA, and that it requires an EAC.

The Project as proposed is not subject to review under the Canadian Environmental Assessment Act, 2012, S.C. 2012, c. 19, s. 52, since it does not meet the definition of a physical activity under the Schedule of Physical Activities in the Regulations Designating Physical Activities SOR/2012-147.

EAO is a neutral agency that manages the review of proposed major projects in British Columbia, as required by the Environmental Assessment Act.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------------|-------------------------|
| Social and cultural effects and the adequacy of EA methodology | <p>Concerns related to the adequacy of Environmental Assessment are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> <p>Social and cultural effects of the project are considered in Part C of the Environmental Assessment Application (Application). Where Aboriginal Groups values and perspectives have been provided to the Proponent regarding environmental, economic, social, heritage or health valued components (VCs), they have been incorporated, where applicable into the Part B assessment of those VCs.</p> | Referred to EAO | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------------------------|-------------------------|
| Strength of Claim assessment and related depth of consultation. | Concerns related to the strength of claim assessment have been referred to EAO and MARR. | Referred to EAO and MARR | None |
| Project’s EA Process and its associated timelines. | Concerns relating to the EA process and its associates timelines were referred to EAO. EAO issued a memo to members of the Working Group on March 18, 2016 in response to questions and concerns related to the EA process and its associated timelines. The Ministry understands that EAO responded to Stz’uminus First Nation’s queries regarding the EA Process and associated timelines. | Referred to EAO | None |
| Effectiveness and nature of the EA process as well as current volume of EAs underway | Concerns relating to the broad concern related to the effectiveness and nature of the Environmental Assessment Process have been referred to EAO. While the Ministry is unable to address the concern related to the current volume of EA’s underway, the Ministry has and will continue to work with Stz’uminus First Nation to support their participation in this particular Project’s review process and to plan for consultation activities in a manner that is mindful of the current volume of referrals that Stz’uminus First Nation is working on. Support to date has included Pre-Application capacity funding. | Referred to EAO | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------|--------------------------------------|
| Lack of resources and funding for First Nations communities. | The Ministry provided funding for the Pre-Application Phase and has committed to providing funding for the Application Review Phase. | Addressed | Funding for Application Review Phase |

ABORIGINAL INTERESTS

There are potential Project related impacts to Stz’uminus First Nation’s title, Rights and culture. Potential effects and the level of effect predicted include:

1. Access to preferred locations for the exercise of Aboriginal Interests (access to river locations for traditional use as a result of changes to physical characteristics of these locations).
2. Availability of preferred resources for the exercise of Aboriginal Interests (availability of fish, marine mammal, vegetation and terrestrial wildlife resources for Traditional Use).
3. Quality of preferred resources for the exercise of Aboriginal Interests (quality of water used for cultural purposes, quality of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use).
4. Quality of experience of exercising, or tied to the exercise, of Aboriginal Interests (quality of experience tied to the traditional use of river locations as a result of changes to the physical characteristics of the location; quality of experience tied to access of instream and upland areas locations for traditional use; quality of experience tied to use of water for traditional purposes; quality of experience tied to the traditional use of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use; and quality of experience while engaged in or tied to traditional use as a result of changes in air quality, noise, ground-borne vibration and to the cultural landscape).

Measureable Effects

Access for traditional use

- Cultural landscape

Quality of experience while engaged in or tied to traditional use

- cultural landscape

No, Negligible or Moderate Effects

Quality of experience while engaged in or tied to traditional use

- Noise

Negligible Effects

Access for traditional use

- Instream locations
- River locations
- Upland locations

ABORIGINAL INTERESTS

Quality for Traditional Use

- Water
- Fish resources
- Marine mammal resources
- Vegetation resources

Quality of experience while engaged in or tied to traditional use

- Fish resources
- Instream locations
- Marine mammal resources
- River locations
- Terrestrial wildlife resources
- Upland locations
- Water
- Vegetation resources

Availability for Traditional Use

- fish resources
- Marine mammal resources
- Terrestrial wildlife resources
- Vegetation resources

No to Negligible Effects

Quality of experience while engaged in or tied to traditional use

- changes to the cultural landscape

No or Negligible Effects

Quality of experience while engaged in or tied to traditional use

- Air quality
- Ground-borne vibration

ABORIGINAL INTERESTS

High, Short-term Probability of Effect

- Disturbance to residential, commercial and industrial land uses
- Disturbance to recreational uses near the new bridge

Moderate, Long-term Probability of Effect

- Disturbance to visual quality

Low, Short-term Probability of Effect

- Barn swallow habitat loss (construction period)
- Physical injury or mortality to fish through crushing or entrainment (construction period)

Low, Long-term Probability of Effect

- Barn owl mortality

No Significant Residual or Cumulative Effects

- Air quality
- Fish and fish habitat
- Heritage resources
- Marine access
- Marine mammals
- River hydraulics and river morphology
- Sediment and water quality
- Terrestrial Wildlife
- Vegetation

The Ministry has developed mitigation measures to address these Potential effects. Residual effects on the exercise of Aboriginal Interests by Stz’uminus First Nation as a result of the Project are not expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Potential impacts to Stz’uminus First Nation’s title, Rights and culture. Identification of future developments should include potential Stz’uminus First Nation’s title and rights resulting from treaty negotiations or proof of title.</p> | <p>Potential Project related impacts to Stz’uminus First Nation’s title, Rights and culture, the level of effect predicted, and mitigation measures are outlined the Application. The Ministry will continue to consult with Stz’uminus First Nation’s to ensure any effects are minimized.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in all Sections of the Application</p> |
| <p>Identification of “other requirements that are relevant to the Project, including international agreements or other agreements” should be included in the Crown’s Constitutional obligations to First Nations“</p> | <p>The Crown’s constitutional obligations are fundamental to consultation with Stz’uminus First Nation and the EA process. The obligations within the context of the EA are addressed in Part C of the Application.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation</p> |
| <p>“Consideration for future uses should include Cowichan Nation Alliance’s plans to re-establish a site on Łæqtinəs/Tl’uqtinus site for residential and/or commercial purposes.”</p> | <p>Noted</p> | <p>Noted</p> | <p>Ongoing consultation</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|---|
| <p>Stz’uminus First Nation’s access to the Fraser River and the potential to displace fishing vessels. Potential interference with Aboriginal fisheries during decommissioning of the Tunnel.</p> | <p>Stz’uminus First Nation’s access to the Fraser River and the potential to displace fishing vessels (access to river locations for traditional use as a result of changes to physical characteristics of these locations) is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined. A measurable direct effect on access to instream locations for traditional use and a negligible effect to upland locations for traditional use has been determined.</p> | <p>Addressed</p> | <p>Ongoing consultation and implementation measures outlined in Section 5.2.4</p> |
| <p>Social effects of the Project such as Stz’uminus First Nation’s knowledge transmission, language loss, dependency and social interaction.</p> | <p>Social effects of the Project on Stz’uminus First Nation’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation measures outlined in all sections of the Application</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| | <p>predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of the Application.</p> | | |
| <p>Protection of Stz’uminus First Nation’s rights to harvest within the Project area.</p> | <p>Stz’uminus First Nation’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures outlined in Table 10.3-1 and Section 10.1.3.4, residual effects on the exercise of Aboriginal Interests by Stz’uminus First Nation as a result of the Project are not expected.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and Implementation of measures outlined in Section 10.1.3.4</p> |
| <p>Assessment of cumulative effects in regards to the inclusion of other reasonably foreseeable projects and activities.</p> | <p>The Ministry’s cumulative effects assessment looked at potential incremental environmental effects of construction and operation of the Project in conjunction with other present and reasonably foreseeable projects that could interact with the potential effects of this Project. The process and methodology used to conduct the cumulative effects assessment, including the identification of potential cumulative effects, identification of additional mitigation measures, and evaluation of any (residual) cumulative effects is outlined in Part B of the Application. Other Projects that are considered in the assessment of Project-related cumulative effects are also listed.</p> | <p>Addressed</p> | <p>None</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|-----------|-------------------------|
| Concern that the overlapping construction period of GMT and Pattullo projects needs to be considered in the assessment. | Rehabilitation of the Pattullo Bridge will be completed by October 2016. The replacement of the Pattullo bridge is in planning stages and a construction period has yet to be established. | Addressed | None |
| Consideration of cumulative effects on aboriginal rights, including measurement against a pre-industrial baseline | The Application will include historical context as outlined relating to changes in use over time by Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by First Nations or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests. | Addressed | None |
| Absence of a comprehensive study of cumulative effects on the Fraser River | While the Ministry acknowledges that Stz’uminus First Nation is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project. | Addressed | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|-----------|-------------------------|
| Length of time tolls are in place | <p>The Province intends to fund the Project, at least in part, through user tolls. This is consistent with the provincial tolling guidelines. Tolling recognizes that those directly benefitting from the new infrastructure in terms of time savings and reliability should help pay for the Project. This ensures that the needed improvements can proceed now, rather than years in the future when improvements will be even more overdue. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application.</p> | Addressed | None |
| Revenue sharing opportunities from tolling | <p>Revenue from tolling is only used to defray the costs of designing, constructing, operating and maintaining highways. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application.</p> | Addressed | None |

| ABORIGINAL CONSULTATION | | | |
|---|---|---------------|---|
| <p>Aboriginal Interests, defined as asserted or determined Aboriginal rights, including title, and treaty rights, are known to overlap or lie in the vicinity of the Project corridor. Potential adverse effects on the exercise of Aboriginal Interests as a result of Project construction and operation have been identified.</p> <p>Mitigation measures to address potential Project-related effects on intermediate components (ICs) and valued components (VCs) associated with the exercise of Aboriginal Interests are expected to be effective. With the application of mitigation, potential effects on the exercise of Aboriginal Interests are predicted to be negligible except in specific cases during Project construction and operation. To address potential effects during Project construction and operation, the development of an Archaeological and Heritage Resources Management Plan is proposed.</p> <p>In addition to mitigation measures proposed to address potential effects on ICs and VCs, ongoing engagement between the Ministry and Schedule B Aboriginal Groups will be undertaken. Such engagement will take place during Application Review and, if the Project is approved, following the issuance of an Environmental Assessment Certificate (EAC). Engagement will involve consultation on management plans and monitoring programs, related to the exercise of Aboriginal Interests.</p> <p>Ongoing engagement is also proposed to address other matters of environmental, economic, social, heritage, and health concern raised Aboriginal Groups during the pre-Application period. With this ongoing engagement, residual effects on the exercise of Aboriginal Interests or other matters of concern as a result of the Project are not expected.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Capacity funding to facilitate participation in the Project review process | Stz’uminus First Nation received funding for the Pre-Application Phase. The Ministry will provide further funding for the Application Review Phase. | Addressed | Consultation regarding funding for the Application Review Phase |
| Appropriate use of information shared by Stz’uminus First Nation as it relates to confidentiality and dissemination | The Ministry understands and respects that certain information shared by Stz’uminus First Nation may be considered confidential. The Ministry is subject to the provisions of the Freedom of Information and Protection of Privacy Act. However, subject to the requirements of applicable laws, the Ministry will respect Stz’uminus First Nation requests to keep information confidential. | Addressed | Appropriate use of confidential information |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|-----------|---|
| Funding for Traditional Use Study | The Ministry signed a funding agreement with Stz’uminus First Nation which provided funding for a Traditional Use Study. | Addressed | None |
| Capacity funding to facilitate participation in the Project review process | Stz’uminus First Nation received funding for the Pre-Application Phase. The Ministry will provide further funding for the Application Review Phase. | Addressed | Consultation regarding funding for the Application Review Phase |
| Appropriate use of information shared by Stz’uminus First Nation as it relates to confidentiality and dissemination | The Ministry understands and respects that certain information shared by Stz’uminus First Nation may be considered confidential. The Ministry is subject to the provisions of the Freedom of Information and Protection of Privacy Act. However, subject to the requirements of applicable laws, the Ministry will respect Stz’uminus First Nation requests to keep information confidential. | Addressed | Appropriate use of confidential information |
| Funding for Traditional Use Study | The Ministry signed a funding agreement with Stz’uminus First Nation which provided funding for a Traditional Use Study. | Addressed | None |

ABORIGINAL PARTICIPATION AND PROJECT RELATED OPPORTUNITIES

The Ministry is actively exploring opportunities to provide benefits, economic and non-economic, to Aboriginal Groups that are directly affected by the Project. Opportunities include employment, training, and contracting as well as participation in environmental enhancement and other components of the Project.

Prior to the Pre-Application Phase of the Project, the Ministry worked with Schedule B Aboriginal Groups to determine appropriate tools to support consultation. Consultation activities were based on the specific needs and preferences of these Aboriginal Groups and the Consultation Plan included individualized plans that were co-developed and reviewed.

The Project’s Aboriginal Consultation Plan has been developed in consultation with Schedule B Aboriginal Groups, in order to meet the Aboriginal consultation requirements as delegated by EAO and to maintain and, where possible, enhance positive working relationships between the Ministry and the respective Aboriginal Groups.

The objectives and requirements of the Aboriginal Consultation Plan are to:

Provide relevant Project-related information in a timely and effective manner that supports an understanding of the nature of the Project and its potential adverse effects on Aboriginal Interests

Plan and implement mutually acceptable consultation activities that support effective participation of Aboriginal communities in the EA as well as related regulatory and permitting processes

Establish and maintain dialogue throughout the EA as a means of providing opportunities to respond to outstanding concerns

Provide opportunities for Aboriginal Groups to share views of the Project with the Ministry and EAO within reasonable timeframes

Provide opportunities for Aboriginal Groups to identify potential adverse effects of the proposed Project on Aboriginal Interests, including cumulative effects and, to the extent appropriate, develop ways to mitigate or otherwise accommodate potential adverse effects

Involve Aboriginal Groups, where possible, in relevant studies including, but not limited to, archaeological fieldwork.

Incorporate community and traditional knowledge in Project components

Document and report to EAO on the Ministry’s Aboriginal consultation program at times specified by EAO.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|------------------|--|
| <p>Opportunities for cultural recognition and naming</p> | <p>The Ministry is exploring opportunities for cultural recognition and naming and will to work with Stz’uminus First Nation on this matter.</p> | <p>Ongoing</p> | <p>Further engagement with Stz’uminus First Nation is planned to explore opportunities related to cultural recognition and naming, art and interpretive signage</p> |
| <p>Project-related employment, training, contracting, and economic development opportunities. Equity and revenue sharing for Stz’uminus First Nation and importance of initiating related discussions with Stz’uminus First Nation during Pre-Application Stage. Aboriginal procurement policy.</p> | <p>The Ministry is committed to working with Stz’uminus First Nation to identify potential opportunities to benefit from the Project. The Ministry acknowledges that Stz’uminus First Nation wants to prepare its membership for employment opportunities and will work with Stz’uminus First Nation to identify ways to support community preparedness.</p> | <p>Ongoing</p> | <p>The Ministry will share information including identification of potential employment, training, contracting and economic development opportunities as it becomes available to support community preparedness. The Ministry welcomes input from Stz’uminus First Nation on the type of information that would be useful.</p> |
| <p>Interest in land recovery at Green Slough</p> | <p>As part of the Project, agricultural land will be protected as much as practical. Once the project is completed, there will be a determination of surplus lands, if any, and disposition will follow the appropriate process including consultation.</p> | <p>Addressed</p> | <p>Determination of surplus lands and consultation</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------|--|
| Adequate training time to take full advantage of potential future Project work activities | The Ministry is committed to working with Stz’uminus First Nation to identify potential opportunities to benefit from the Project. Ministry acknowledges that Aboriginal Groups want to prepare their membership for employment opportunities and will work with Stz’uminus First Nation to identify ways to support community preparedness. | Ongoing | The Ministry will share information as it becomes available to support community preparedness and welcomes input from Aboriginal Groups on the type of information that would be useful. |

4.1 RIVER HYDRAULICS

The proposed bridge will have a clear-span, which eliminates potential changes to river hydraulics or river morphology resulting from the new structure. The Fraser River South Arm is dynamic with scour in the order of several metres during freshet and migrating sand dunes with heights of up to four metres. Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. Tunnel removal is expected to result in temporary bed lowering between the Tunnel and Lulu Island-Delta water main; however, no permanent effect on the Lulu Island-Delta watermain is expected.

Effects

A negligible effect to access to river locations for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of river locations has been determined.

Mitigation

Development of a mitigation plan to ensure protection to the Lulu-island-Delta water main.

Monitor the riverbed within 100 metres upstream and downstream of the watermain.

Stockpile appropriately-sized rock near the Project site, for priority scour protection repairs at the water main crossing.

Establish on-call contracts with a qualified registered professional and a qualified marine contractor prior to Tunnel removal, to ensure that scour protection repairs can be designed and implemented on short notice

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|--|
| <p>Change in flow rates after Tunnel removal</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects to river hydraulics and river morphology within the Fraser River South Arm.</p> <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor.</p> <p>River Hydraulics and River Morphology are addressed in Section 4.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4</p> |
| <p>Factoring in extreme weather events in River Hydraulics model</p> | <p>Extreme weather events are considered and planned for. River Hydraulics and River Morphology are addressed in Section 4.1.4.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|------------------|--|
| <p>Potential for contaminants in the tunnel and how this may affect tunnel decommissioning.</p> | <p>The Ministry will consult with Fisheries and Oceans Canada and Port Metro Vancouver regarding Tunnel decommissioning, and will incorporate the requirements of these agencies in the planning and implementation of decommissioning activities.</p> <p>If potentially hazardous building materials are identified in the Tunnel, a detailed plan for removing and appropriately disposing of such material will be developed prior to initiating decommissioning activities. Any potentially hazardous material identified will be managed in accordance with applicable legislation, including the B.C. Hazardous Waste Regulation, B.C. Reg. 63/88, and the Workers’ Compensation Board of B.C. Occupational Health and Safety Regulation, B.C. Reg. 296/97.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in 4.1.4 and 4.2.4</p> |

4.2 SEDIMENT AND WATER QUALITY

The proposed bridge will have a clear-span, which reduces potential effects to sediment and water quality within the Fraser River South Arm. During Tunnel decommissioning, a minor, temporary increase in turbidity, as compared with baseline conditions, is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.

Project activities undertaken in the upland ditch systems will follow Standards and Best Practices for Instream Works.

Effects

A negligible effect on quality of water used for cultural purposes has been determined.

A negligible effect on quality of experience tied to use of water for cultural purposes has been determined.

Mitigation

Avoid effects through Project design.

Incorporate a stormwater collection and distribution system (stormwater detention ponds and biofiltration swales) into bridge design that will convey and discharge stormwater runoff to appropriate upland infrastructure for proper treatment.

Develop Construction Environmental Management and Operational Environmental Management plans.

Control suspended sediment during Tunnel decommissioning. Employment of construction methods that minimize levels of Project-induced turbidity. Use spoil barges equipped with sediment containment system (filter cloth, concrete lock blocks, straw bales) to transport removed material off-site.

Control suspended sediment during Project construction in and adjacent to Deas and Green Sloughs. Use of sediment control measures such as turbidity curtains and de-watered cofferdams.

Monitor water quality during construction.

Use timing windows for undertaking in-stream works.

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology or sediment and water quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------------------------|---|
| Potential effects of run off and drainage | The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciative change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected. Sediment and Water Quality is addressed in Section 4.2 of the Application. | Addressed in Application | Implementation of mitigation measures outlined in Section 4.2.4 |
| Effect of the Tunnel on dissolved oxygen content within the river. | The Ministry is following up with Stz’uminus First Nation to obtain further clarification regarding their concern regarding the effect of the Tunnel on dissolved oxygen content within the river. | Ongoing | Clarification regarding concern |
| Impact of potential pollutants and contaminants within the tunnel walls on the river if left in place. | The tunnel decommissioning is anticipated to involve the removal of the four in-river sections of the Tunnel. | Addressed | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|--|
| <p>Improved ditches will result in less filtering of deleterious materials</p> | <p>Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.2.4</p> |
| <p>Use and disposal of dredged and other, material in the river as well as general concerns related to dredging of the Fraser River.</p> | <p>Dredging to deepen the river is not a component of this Project and the Ministry is unaware of any plans by others to dredge the river deeper. The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. This is outlined in Sections 1.1.7.2 (Construction), 4.1 (River Hydraulics) and 4.2 (Water Quality and Sediment) of the Application.</p> | <p>Addressed in Application</p> | <p>None</p> |

4.4 FISH AND FISH HABITAT

The proposed bridge will have a clear span over the Fraser River South Arm and Deas Slough, avoiding or minimizing Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Given the disturbed nature of much of the Project alignment, re-vegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by improvements to local water quality; removal of non-native species; and replanting with species that provide habitat value for fish and wildlife.

Effects

- A negligible effect on the availability of fish resources for traditional use has been determined.
- A negligible effect on quality of fish resources for traditional use has been determined.
- A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

Mitigation

- Avoid effects through Project design.
- Apply best management and environmental management practices.
- Develop Construction Environmental Management and Operational Environmental Management plans.
- Use timing windows for undertaking in-stream works.
- Erosion and sediment control.
- Habitat enhancement and offsetting.

Residual & Cumulative Effects

- There is a low, short-term potential of physical injury or mortality to fish through crushing or entrainment during the construction period.
- No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|--------------------------|---|
| Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon | The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon and salmon to Stz’uminus First Nation. Potential Project-related effects on fish and fish habitat are presented in Section 4.4 of the Application. | Addressed in Application | Implementation of mitigation measures outlined in 4.4.4 |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|--|
| <p>Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon</p> | <p>Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources can be mitigated effectively by scheduling such activities during periods of low tide, when work can be completed under shall water conditions or in the dry, thereby minimizing potential effects. No Project-related residual or cumulative effects on underwater noise conditions are expected. Underwater Noise and Fish and Fish Habitat are addressed in Sections 4.3 and 4.4 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.3.4 and 4.4.4</p> |

4.6 MARINE MAMMALS

Marine mammals, specifically harbor seals and sea lions, are known to use marine areas within the Project alignment. Other species of conversation interest, including southern resident killer whales, do not occur in the Fraser River. Underwater noise during construction is the key area of focus for potential Project-related effects on marine mammals. Underwater noise in the Fraser River South Arm from existing sources currently exceeds thresholds for disturbance to marine mammals approximately 20% of the time. The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.

Effects

A negligible effect on the availability of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

Mitigation

Apply standard industry and best management practices to activities such as pile driving that have the potential to generate underwater noise to ensure sound thresholds for the protection of marine mammals are adhered to.
 Marine Mammal Management Plan to be incorporated into the Construction Environmental Management Plan
 Monitor underwater noise.

Cumulative Effects

No significant Project-related residual or cumulative effects on marine mammals are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Stz’uminus First Nation has not voiced any specific issues or concerns with respect to Marine Mammals. | | | |

4.7 VEGETATION

The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development.

Project components and activities will be primarily located within the existing Highway 99 right-of-way, where the vegetation consists mainly of grassy, mowed verges. Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary marsh that occur in the vicinity of the Project. No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.

Effects

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to best management and environmental, terrestrial vegetation and wildlife management practices. Apply best practices such as flagging of at-risk ecosystems to avoid encroachment during construction.

Offset and enhance habitat. Create comparable habitat within the Project alignment to offset unavoidable potential Project-related effect, limited to a small reduction in area of the cattail marsh that overlaps with Project components. Replant disturbed areas with native species.

Invasive species management plan will included in the Construction Environmental Management Plan

Cumulative Effects

No significant Project-related residual or cumulative effects on vegetation are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------------------------|---|
| Invasive plant species and proposed plans to manage presence during construction | Mitigation and management of invasive species are presented in Section 4.7 of the Application. The Ministry will develop and implement an Invasive Species Management Plan as part of the Construction Environmental Management Plan. | Addressed in Application | Implementation of mitigation measures outlined in Section 4.7.4 |
| Culturally significant plants should be used in planting plans | Planting plans will be developed during later stages of Project planning and design. Opportunities for inclusion of culturally significant plants in in planting plans will be considered at that time. The Ministry will consult Aboriginal Groups on the development of these plans. | Addressed | The Ministry will develop planting plans with consultation from Aboriginal Groups |

4.8 TERRESTRIAL WILDLIFE

The Highway 99 corridor is a highly developed area and terrestrial wildlife has generally adapted to this current condition. Terrestrial wildlife along Highway 99 consists primarily of raptors, riverine birds, and small mammals. Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge. No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.

Effects

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to terrestrial vegetation and wildlife management best practices such as spatial and temporal avoidance, pre-construction surveys and nest survey protocols, wildlife salvage and translocation, flagging and management of sensitive areas, and timing window restrictions.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term probability of barn swallow habitat loss during the construction period. The new bridge will provide new nesting opportunities for barn swallows.

There is a low, long-term probability of barn owl mortality.

No significant Project-related residual or cumulative effects on terrestrial wildlife are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|--|
| <p>Potential light and noise effects on wildlife and fish.</p> | <p>The Ministry understands that Stz’uminus First Nation is concerned with the potential effects of light and noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |
| <p>Potential effects of the bridge structure on species such as waterfowl and migratory birds.</p> | <p>The Ministry understands that Stz’uminus First Nation is concerned with the potential effects of the new bridge structure on species such as mammals, waterfowl, bats, eagles and migratory birds. Installation of flight deflectors such as hedgerows at appropriate locations along the highlight will mitigate potential Project-related increase in traffic collision risk. Terrestrial Wildlife in addressed in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |

4.9 AIR QUALITY

Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in.

Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include a 35% reduction in particulate matter emissions, as compared with a 14% reduction without the Project; a 47% reduction in volatile organic compound emissions, as compared with a 40% reduction without the Project; and no exceedances of the current most stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.

The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.

Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.

Effects

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

Mitigation

Minimize effects through Project design.

Implement recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.

Measure and monitor vehicle emissions and road dust during Project operation.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--------|---------------------------|--------|-------------------------|
|--------|---------------------------|--------|-------------------------|

| | | | |
|--|---|---------------------------------|--|
| <p>Potential effects to air quality, particularly as it relates to terrestrial wildlife.</p> | <p>The Ministry understands that Cowichan Tribes is concerned with the potential effects of air quality, particularly on terrestrial wildlife species. Projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in. Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in improvement in air quality. The new bridge will allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as the Tunnel portals, where they accumulate today. Effects on air quality during Project construction will be minimized through implementation of recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |
|--|---|---------------------------------|--|

4.10 ATMOSPHERIC NOISE

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the highway but do not exceed what is acceptable for residential, educational or institutional facilities.

Effects

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

Mitigation

Minimize effects through Project design.

Adhere to construction best practices and the Ministry’s 2014 *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways*.

Develop and implement a Noise Management Plan.

Noise monitoring program.

Site specific schedules and activities.

Residual & Cumulative Effects

With the application of mitigation, no significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|---|
| <p>Increase in traffic and consequent increase in associated noise and vibration due to the increases capacity of the new bridge.</p> | <p>The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new Bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment, after mitigation, are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the Highway but do not exceed what is acceptable for residential, educational or institutional facilities. Atmospheric Noise is addressed in Section 4.10 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.10.4</p> |
| <p>Choice of building materials in relation to noise and vibration</p> | <p>The Ministry confirms that appropriate building materials will be used to mitigate noise and vibration. Mitigation in accordance with the Ministry’s 2014 Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways will be implemented, as warranted, at select locations to avoid or minimize potential Project-related increase in post-construction noise levels. Atmospheric Noise is addressed in Section 4.10 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.10.4</p> |

5.2 MARINE USE

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, and sorting and booming, as well as commercial, recreational and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place within the vicinity of the Project.

A clear span crossing of the Fraser River is proposed to avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span to improve navigation in and out of the slough.

Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.

Effects

During construction, a measureable effect on access to instream locations for traditional use has been determined.

During construction, a measurable effect on quality of experience tied to access of instream locations for traditional has been determined.

During operation, a negligible effect on access to instream locations for traditional use has been determined.

During construction, a negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Develop and implement a Marine Access Management Plan to ensure that important marine use activities can be reconciled with temporary constraints associated with Project construction.

Establish communications protocols to advise in-stream construction activities.

Ensure appropriate lighting and marking for safe navigation.

Establish navigation protection zones during construction to avoid or minimize impact on marine use.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|---|
| <p>Potential effects of construction during fishing season on fishing activities. Impacts of Tunnel decommissioning on Aboriginal fisheries, specifically as it relates to timing.</p> <p>“The proposed project has a direct impact on how we are able to use and navigate the areas surrounding the proposed project, and the impact of the project as it limits this ability needs to be considered in the Aboriginal Interests Assessment.”</p> <p>“Future exercise of our Aboriginal rights to fish (and also to harvest) including in-water and upland of the South arm of the Fraser should be considered when assessing project impacts of our interests.”</p> | <p>Potential interference with Stz’uminus First Nation fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> <p>The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4</p> |
| <p>Facilitation of increased shipping in the river</p> | <p>The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river.</p> | <p>Addressed</p> | <p>None</p> |

5.3 LAND USE

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta.

The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect regional growth trends or current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.

Once the new bridge becomes operational, recreational experience in its vicinity is expected to change due to improvements in local air quality, shoreline restoration of Deas Island, and re-vegetation of areas currently supporting highway infrastructure; improved connectivity across the Deas Island Regional Park resulting from removal of the Tunnel portals; and shading adjacent to the bridge, overhead noise, and changes in local viewsapes.

The Project will not result in changes to existing land use beyond small amounts of land, outside of the existing right-of-way, that area required for the Project.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Residual & Cumulative Effects

There is a low, short-term probability of disturbance to residential, commercial and industrial land use during construction.

There is a moderate , short-term probability of disturbance to recreational users near the new bridge during construction

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---------------------------|--------|-------------------------|
| Stz’uminus First Nation has not voiced any specific issues or concerns with respect to Land Use | | | |

6.1 HERITAGE RESOURCES

The Project is located in an area where substantial historical development has occurred and the majority of the Project alignment is characterized as having low archaeological potential. No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.

Effects
 A negligible effect on access to upland locations for traditional use has been determined.
 A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.
 No to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.
 A measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation
 Develop and implement a Heritage Resources Management Plan, which will include a chance find procedure, to avoid impacts to previously unknown heritage resources that may be encountered during Project construction and operation.
 Undertake additional archaeological surveys.

Residual & Cumulative Effects
 No significant Project-related residual or cumulative effects on heritage resources are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|--------------------------|--|
| Protection of archaeological and heritage resources, including intangible heritage sites and specific concern for any effects on the Łæqtinəs/Tl’uqtinus site and potential archaeological values at interchanges | Ministry acknowledges that protection of archaeological sites as well as intangible heritage sites are of utmost importance to Stz’uminus First Nation. All Aboriginal Groups have been provided with a comprehensive list of these sites, the Archaeological Overview Assessment, the Archaeological Impact, and Heritage Resources Overview Assessment. Appropriate measures will be taken to ensure the protection of archaeological and heritage resources as outlined in Section 6.1. | Addressed in Application | Implementation of mitigation measures as outlined in Section 6.1.4 |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|-----------|--|
| Participation in archaeological fieldwork and review of archaeological draft reports | Stz’uminus First Nation participated in all archaeological field work to date and was provided the opportunity to review draft archaeological reports. | Addressed | Stz’uminus First Nation will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports. |
| Ethnographical content in reports does not accurately reflect Stz’uminus First Nation’s historical presence within the Project area | The Ministry noted Stz’uminus First Nation’s concern that ethnographical content in Project reports does not accurately reflect Stz’uminus First Nation’s historical presence within the Project area. The Ministry continues to work with Stz’uminus First Nation to address this concern. | Ongoing | Ongoing consultation |

7.0 HUMAN HEALTH

Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health. The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options. The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased active and public transportation, improved traffic safety, improvement connectivity and access, improved emergency response, and economic development opportunities.

Future Project-related consultation with Aboriginal groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.

Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations, and emergency response.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

A negligible effect on access to instream locations for traditional use has been determined.

7.0 HUMAN HEALTH

A negligible effect on quality of experience tied to access of instream locations for traditional has been determined.
 A negligible effect on access to upland locations for traditional use has been determined.
 A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation
 Implement proven mitigation measures, effectively used during construction of projects such as the South Fraser Perimeter Road and Port Mann / Highway 1 Improvement, to ensure that temporary increases in ambient noise levels and air emissions during construction do not result in health effects.
 Implementation of mitigation measures outlined in Fish and Fish Habitat, Marine Mammals, Vegetation, Terrestrial Wildlife, Air Quality, Atmospheric Noise, Marine Use and Land Use.

Residual & Cumulative Effects
 No significant Project-related residual or cumulative effects on human health are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---|-------------------------|
| Aboriginal health is not currently being considered in the assessment | Aboriginal health was considered in the assessment of potential Project-related effects on human health, including community and social factors. Human Health is addressed in Section 7.1 of the Application. | Addressed in Assessment and Application | None |
| Current conditions along the foreshore and in the Fraser River are not properly understood and have not been considered in the Human Health Assessment | Current conditions along the foreshore were considered in the assessment of potential Project-related effects on human health, including community and social factors. Human Health is addressed in Section 7.1 of the Application. | Addressed in Assessment and Application | None |

8.0 ACCIDENTS AND MALFUNCTIONS

Adherence to the practices and procedures contained in the Construction Environmental Management Plan will minimize the potential for accidents and malfunctions to occur.
 In general, replacement of the Tunnel with a new crossing and the proposed highway improvements are expected to lower the risk of accidents and malfunctions during highway operations and maintenance

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|--------------------------|--|
| Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations | As outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan), an Emergency Response and Spill Contingency Plan will be developed. The Plan will outline how construction personnel will prevent, prepare for, respond to, and clean up spills. | Addressed in Application | Implementation of mitigation measures outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan) |
| Contaminants from automobile emission currently captured in Tunnel. New Bridge will send emissions directly into the air and Fraser River and settle on the foreshore | Automobile emissions are currently released from the Tunnel through a series of vents. Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in. Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. The new bridge will allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as the Tunnel portals, where they accumulate today. Effects on air quality during Project | Addressed | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|------------------|-------------------------|
| | <p>construction will be minimized through implementation of recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.</p> | | |
| <p>New Bridge could “unleash pent-up demand” and create even more congestion</p> | <p>The Project has been designed to address issues related to current and future traffic safety, congestion and reliability, and to help achieve regional mode share targets by facilitating travel across the Fraser River by transit, HOVs, cycling and walking. During operations, the Project will provide travel time savings for commuters or 25-35 minutes per day, improve safety with a forecast 35 percent reduction in collisions, and support provincial and regional strategies to encourage mode shift to transit and carpooling. As proposed, Project-related improvements, including tolling, will moderate traffic growth while effectively serving forecast demand at the crossing.</p> | <p>Addressed</p> | <p>None</p> |

APPENDIX N

Tsawwassen First Nation

1.0 Introduction

This appendix provides a summary of the information presented in Part C Aboriginal Consultation (Part C) of the Application for an Environmental Assessment Certificate (the Application) regarding the assessment of effects on Aboriginal Interests. Aboriginal Interests are defined as asserted or determined Aboriginal rights, including title, or treaty rights. This appendix presents the information specific to Tsawwassen First Nation (Tsawwassen).

The organization of the information presented generally follows Part C and includes the following sections:

- Consultation;
- Community Profile;
- Existing Conditions;
- Potential Effects;
- Mitigation;
- Residual Effects; and
- Summary and Conclusion.

For more detailed information on the effects assessment on Aboriginal Interests related to Tsawwassen, refer to the following sections of Part C:

- Consultation with Tsawwassen (**Section 10.1.2.10**);
- Tsawwassen community profile (**Section 10.1.1.10**);
- Description of existing Tsawwassen Aboriginal Interests (**Section 10.1.3.2**);
- Assessment of potential effects of the Project on the exercise of Tsawwassen Aboriginal Interests (**Section 10.1.3.3**);
- Mitigation relating to potential effects on Aboriginal Interests (**Section 10.1.3.4**); and
- Residual effects on Tsawwassen Aboriginal Interests following application of mitigation (**Section 10.1.3.5**).

A summary of the Aboriginal Interests Assessment for Tsawwassen is also provided in **Section 10.1.3.8**.

The summary presented in this appendix also incorporated information found in the Tsawwassen Overview Table (**Appendix N2**), which provides detailed information regarding:

- Tsawwassen’s issues and concerns identified to date;
- Identification of potential effects on VCs and ICs that relate to the assessment of effects on Tsawwassen’s Aboriginal Interests;
- The Ministry’s response to specific issues and concerns raised by Tsawwassen;
- The status of these issues and concerns; and
- Next steps required to address outstanding issues and concerns.

2.0 Consultation

This section provides information regarding the consultation activities that the EAO and Ministry carried out prior to submission of the Application.

2.1 EAO-led Consultation Activities

2.1.1 Capacity Funding

When a provincial agency is a proponent of a project going through a provincial EA under the British Columbia *Environmental Assessment Act* (BCEAA), that agency provides funding to Aboriginal Groups to support their involvement in pre-Application and Application review phases in place of EAO providing such funding. The Ministry’s provision of capacity funding is discussed in the following section, Proponent-led Consultation Activities.

2.1.2 Participation in Working Group

EAO invited Tsawwassen and all other Aboriginal groups identified in Schedule B of the Section 11 Order to participate as members of a Working Group.

During the Pre-Application stage, EAO led two Working Group meetings where the Ministry presented information on the Project and the environmental assessment process and received and responded to comments on those presentations. Tsawwassen attended the first of the two Working Group meeting; materials were provided for the Working Group meeting they did not attend.

The first Working Group meeting, held January 2016, focused on the environmental assessment process, Project overview and update, Key Areas of Study, draft Application Information Requirements overview, and preliminary conclusions from study results.

Tsawwassen also participated in the completeness review of the Application that considered whether the Application included information requirements set out in the Application Information Requirements.

It is assumed that Tsawwassen will continue as an active member of the Working Group through the environmental assessment process.

2.2 Proponent-led Consultation Activities

The Ministry began consultation with Tsawwassen in early 2013 in order to identify the nature and scope of Tsawwassen's Aboriginal Interests and how they might be impacted by the Project. Following is a summary of consultation activities led by the Ministry with Tsawwassen. A more detailed discussion is provided under the Tsawwassen section in **Section 10.1.2.10 Overview of Consultation with each Schedule B Aboriginal Group**. The following sections represent the main activities undertaken in support of Proponent-led consultation and include the following:

- Provision of capacity funding;
- Traditional use, traditional knowledge and other studies;
- Initial Consultation Phase Activities;
- Pre-Application Phase Activities; and
- Concerns Identified to Date.

2.2.1 Capacity Funding

The Ministry entered into a Participation Funding Agreement, including the Initial Consultation and Pre-Application phases for consultation, with Tsawwassen. The Ministry has been working with Tsawwassen regarding their needs for capacity funding to facilitate their participation in the Application Review Phase. Consultation activities that are anticipated to be undertaken during the Application Review phase that will be supported by capacity funding include participation in technical reviews and analyses, involvement in ongoing consultation activities, and presentation of key information regarding their respective Aboriginal Interests.

2.2.2 Traditional Use, Traditional Knowledge & Other Studies

The Ministry provided additional funding to Tsawwassen for the preparation and submission of the traditional use study: *George Massey Tunnel Replacement: Project Impact Study: An assessment of potential impacts of the George Massey Tunnel Replacement Project on aspects of the TFN Final Agreement, and other considerations*. The purpose of such studies is to

identify Aboriginal input and traditional knowledge for inclusion in the EA. In addition, studies were funded to enhance the Ministry's understanding of Aboriginal Interests and Aboriginal Group's past, present and desired future use as it pertains to the exercise of Aboriginal Interests within the Project area and the potential adverse effects on identified Aboriginal Interests.

2.2.3 Examples of Consultation Activities

A number of consultation activities were undertaken with Tsawwassen during both the Initial Consultation Phase and the Pre-Application Consultation Phase as follows:

Initial Consultation Phase Activities – The Ministry recognized the importance and value of early engagement with Schedule B Aboriginal Groups and undertook an Initial Consultation Phase prior to the Pre-Application Phase. The Initial Consultation Phase concluded in December 16, 2015 with submission of the Project Description and Key Areas of Study document. The focus of the Initial Consultation Phase was collection of baseline information and sharing of draft EA-related documents (i.e. Project Description and Key Areas of Study, Application Information Requirements (AIR)). The main consultation activities the Ministry undertook with Tsawwassen included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Tsawwassen;
- Funding for Tsawwassen's participation in Project consultation activities and EA process;
- Tsawwassen participation in field studies;
- Site visit;
- Review of draft EA documents such as the Project Description and Key Areas of Study, Heritage Resources Overview Assessment/Archaeological Overview Assessment, Heritage Resources Assessment, draft AIR, and Aboriginal Consultation Plan;
- Meetings with Tsawwassen leadership, staff, consultants, elders and membership; and
- Response and follow up with Tsawwassen regarding the identification and resolution of issues.

Pre-Application Consultation Phase Activities - The Pre-Application Consultation Phase began with the filing of the Project Description and Key Areas of Study on December 16, 2015 and concluded with the submission of the Application. This phase included the issuance of Section 11 Order, AIR development and collection of baseline information (may include submission of permit applications). The main consultation activities the Ministry undertook with Tsawwassen included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Tsawwassen;
- Funding for Tsawwassen’s participation in Project consultation activities and EA process;
- Meetings with Tsawwassen leadership, staff, consultants, elders and membership;
- Tsawwassen participation in fieldwork;
- Tsawwassen participation in the EA Working Group;
- Review of draft EA documents such as the Application Information Requirements, Aboriginal Consultation Plan, and Aboriginal Consultation Reports;
- Review of draft Part C content for the Application; and
- Response and follow up with Tsawwassen regarding the identification and resolution of issues.

2.2.4 Concerns Identified to Date

As outlined above, Tsawwassen’s concerns, identified through consultation undertaken to-date, are presented in **Appendix N2 Tsawwassen First Nation Overview Table**. The Ministry’s response to Tsawwassen’s key concerns regarding potential impacts on Tsawwassen’s Aboriginal Interests are outlined below:

Table 1 **Concerns Identified to Date**

| Concerns Identified to Date | Response |
|--|---|
| Obligations to Tsawwassen as a Treaty Nation must be recognized and consultation must be undertaken as set out in the Tsawwassen Final Agreement. | The Ministry recognizes and respects the obligations to Tsawwassen as a Treaty Nation and will continue to undertake consultation according to the requirements outlined in the Tsawwassen Final Agreement. |
| Potential effects to Tsawwassen Right to Harvest <ul style="list-style-type: none"> • Fish • Marine Mammals • Vegetation • Terrestrial Wildlife | Tsawwassen’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife), residual effects on the exercise of Aboriginal Interests by Tsawwassen as a result of the Project are not expected. |
| Aboriginal participation and Project-related opportunities <ul style="list-style-type: none"> • Potential employment, training, contracting and economic development opportunities • Community preparedness • Cultural recognition and naming • Revenue sharing opportunities from tolling | The Ministry is committed to working with Tsawwassen to identify potential employment, training, contracting and economic development opportunities and to identify ways to support community preparedness. The Ministry is exploring opportunities for cultural recognition and naming and will work with Tsawwassen on these opportunities. The provincial tolling strategy stipulates that revenue from tolling may only be used to defray the costs of designing, constructing, operating and maintaining highways. |

| Concerns Identified to Date | Response |
|--|---|
| <p>Effects to fish and fish habitat</p> <ul style="list-style-type: none"> • Importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon • Potential effects of pile driving, blasting and underwater noise generated by Tunnel decommissioning and other construction activities • Accommodation of construction windows for fish cycle spikes (i.e. 4 year sockeye and 2 year pink) | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon, salmon to Tsawwassen and is committed to avoiding or mitigating any potential effects.</p> <p>The Ministry designed a clear span bridge over the Fraser River South Arm and Deas Slough to avoid or minimize Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat.</p> <p>Tsawwassen’s Fisheries Department continues to be very helpful in the review of Green Slough concepts.</p> <p>As outlined in Section 4.3 (Underwater Noise), sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources will be effectively mitigated by scheduling activities during period of low tide, when work can be completed under shallow water conditions or in the dry.</p> <p>To the extent that is technically feasible and viable, sediment removal will be undertaken between July 16th and February 28th, the least-risk timing window for the protection of juvenile salmon and eulachon.</p> |
| <p>Environmental Assessment (EA):</p> <ul style="list-style-type: none"> • Adequacy of methodology to address social and cultural effects • Process and associated timelines • CEAA review | <p>The Ministry acknowledges the importance of Tsawwassen’s involvement in the environmental assessment process and is committed to funding Tsawwassen’s participation in the Initiation Consultation and Application Review phases.</p> <p>Tsawwassen’s concerns related to Environmental Assessment including the adequacy of methodology to address social and cultural effects, process and associated timelines are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> <p>The Ministry reviewed the need for a federal review with the federal government. The Project did not meet the Canadian Environmental Assessment Agency (CEAA) requirements for a federal review. Federal agencies, including Environment and Climate Change Canada, are members of the Technical Working Group.</p> |

| Concerns Identified to Date | Response |
|---|---|
| <p>Social effects of the Project on Tsawwassen’s ability to transfer knowledge, language and participate in socio-cultural practices</p> | <p>Social effects of the Project on Tsawwassen’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of Part C of the Application.</p> |
| <p>Cumulative effects:</p> <ul style="list-style-type: none"> • Consideration of cumulative effects on Aboriginal rights • Absence of comprehensive study on cumulative effects on the Fraser River | <p>The Application includes historical context relating to changes in use over time by Tsawwassen and other Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by Tsawwassen or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests.</p> <p>While the Ministry acknowledges that Tsawwassen is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project.</p> |
| <p>Potential increase in vessel traffic on the Fraser River as a result of the decommissioning of the Tunnel</p> | <p>The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river.</p> |

| Concerns Identified to Date | Response |
|---|---|
| Potential effects on Fraser River flow rates after Tunnel removal | Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Flow rates are discussed in Section 4.1 (River Hydraulics). |
| Potential effects of run off and drainage | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will ensure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected.</p> <p>Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> |

3.0 Community Profile – Tsawwassen First Nation

Tsawwassen First Nation is based on the southern aspect of Fraser River delta, on the west side of the peninsula that separates Boundary Bay from the Strait of Georgia. Pursuant to the Tsawwassen First Nation Final Agreement (TFNFA), which came into effect on April 3, 2009, Tsawwassen is a self-governing community led by a chief and council that are elected every three years. The current three-year term for the five-member council expires in April 2019.

Under the TFNFA, Tsawwassen acquired 724 ha of treaty settlement lands, including 290 ha of former reserves and 372 ha of former Provincial Crown Land. These 662 ha of Tsawwassen Lands are located on the upland areas between the ferry terminal at Tsawwassen and the container port at Roberts Bank. Tsawwassen Lands are owned by and under the jurisdiction of Tsawwassen First Nation, and are guided by the Tsawwassen First Nation Land Use Plan. An additional 62 ha of fee simple land near Boundary Bay and on the Fraser River (along Canoe Pass) are owned by the Tsawwassen First Nation, but are under the jurisdiction of the Corporation of Delta. Roughly half (184) of the Tsawwassen First Nation's registered population (365) reside on Tsawwassen Lands. The Project area does not overlap any of the treaty settlement lands of the Tsawwassen First Nation.

In addition to fee simple interests, the TFNFA secures harvesting rights to Tsawwassen members in areas located within Tsawwassen Territory, defined as the area of land that Tsawwassen identified in its Statement of Intent to the British Columbia Treaty Commission. This territory extends from the southern Gulf Islands to the area around Pitt Lake. Rights under the TFNFA are limited by measures necessary for conservation, public health, or public safety.

The Project area lies within Tsawwassen Territory, and is situated in or near several harvesting areas defined in the TFNFA relating to fishing, wildlife and migratory bird harvesting, and plant gathering.

3.1 Tsawwassen Aboriginal Interests: Existing Conditions

This section provides a high level of summary of past, present, and desired future use of the proposed Project area and surroundings for traditional purposes that are or may be connected with the exercise of Tsawwassen's Aboriginal Interests. A more detailed discussion, including sources used, is provided under Tsawwassen in **Section 10.1.3.2 Existing Conditions**.

Tsawwassen has confirmed treaty rights under the TFNFA, which are limited by measures necessary for conservation, public health, and public safety. These treaty rights include:

- Tsawwassen First Nation Fishing Right, including harvesting aquatic plants;

- Tsawwassen First Nation Right to Harvest Wildlife;
- Tsawwassen First Nation Right to Harvest Migratory Birds;
- Tsawwassen First Nation Right to Gather Plants;
- Tsawwassen First Nation Right to Harvest Renewable Resources; and
- Tsawwassen First Nation Right to Practice Tsawwassen First Nation Culture.

3.1.1 Fishing

- The Tsawwassen Fishing Area, which applies to fish and aquatic plants but excludes intertidal bivalves includes the waters of the Main Arm of the Fraser River westerly of the power lines downstream of the Port Mann Bridge, the waters of the North Arm of the Fraser River from the junction of the Main Arm downstream to the Arthur Laing Bridge, the Middle Arm of the Fraser River, the South Arm of the Fraser River, and parts of the waters of the Strait of Georgia and Boundary Bay. Tsawwassen report that they actively fish in the South Arm of the Fraser River and within the Project area.
- Fish, as defined under the TFNFA, includes fish, intertidal bivalves and other shellfish, crustaceans, and marine animals (excluding cetaceans), the parts of these fish, as well as their the eggs, sperm, spawn, larvae, spat, juvenile stages and adult stages.
- The right to harvest fish allows designated members of the Tsawwassen to exercise the right for domestic purposes and to trade or barter those fish among themselves or with other Aboriginal people resident in BC. Domestic allocations for sockeye, chum, pink, chinook, and coho salmon, which are centrally important to Tsawwassen, are calculated using formulas described in the TFNFA.
- In addition to domestic fishing, the Tsawwassen First Nation Harvest Agreement, which is a separate contractual arrangement between the parties to the TFNFA that does not “create, recognize or affirm aboriginal or treaty rights”, is intended to increase commercial fishing capacity for Tsawwassen. The Tsawwassen First Nation Harvest Agreement provides for an annual commercial allocation for salmon.
- Fraser River eulachon, a traditional species, are fished in Canoe Passage in limited quantities for specific domestic purposes. Tsawwassen report that eulachon, once very abundant, in particular in Canoe Passage, is now only available for distribution to Elders.
- Canoe Passage was once a key sturgeon harvesting area, but now sturgeon cannot be kept due to conservation concerns.
- Groundfish (i.e., rockfish, lingcod, halibut, dogfish, and sole) may also be harvested year-round for domestic purposes under the TFNFA, but this harvest has not occurred since the TFNFA came into effect. Tsawwassen report the return of halibut to the Roberts Bank area, and the harvesting of dogfish has occurred in the shallows near the Roberts Bank terminal. Sole, and flounder, present in Canoe Passage, are reported to be small, and some flounder appear to be diseased.

- Since the TFNFA came into effect, four to five licences have been issued for the domestic crab harvest, targeting Dungeness, graceful, and red rock species; domestic harvests of crab are currently not subject to allocation limits and are permitted throughout the year. Tsawwassen report commercial crab harvesting currently occurs in Crab Management Area I, from June through November.
- Shrimp and prawn may be harvested for domestic purposes at any time of year under the TFNFA; however, although a harvest document was issued in 2010, no recorded harvests have been made since the TFNFA came into effect. Tsawwassen members report an interest in harvesting prawn on the eastern side of the Strait of Georgia.
- Intertidal bivalves may be harvested in the Tsawwassen Intertidal Bivalve Fishing Area. There has been no harvest of intertidal bivalves in the designated areas since the TFNFA came into effect. Tsawwassen has expressed interest in developing shellfish aquaculture.
- Tsawwassen report that from Sturgeon Bank south to Point Roberts, clams, cockles, mussels, oysters and abalone were once harvested by their members for food and other purposes such as trade and ceremonial regalia. Boundary Bay was considered an important harvesting area for bivalves, especially clams, cockles, and oysters, while scallops, sea cucumbers were taken from Boundary Bay through to Canoe Passage. Tsawwassen Elders report barnacles, which were harvested by being scraped from rocks, have reduced in size over the years. They also note that abalone, along with a large oyster bed (lying just south of the B.C. Ferries Terminal), began to disappear after development in the Roberts Bank area (i.e. Roberts Bank terminals and B.C. Ferry Terminal). The Elders have also reported that they stopped harvesting shellfish from the area before DFO put in place the existing biotoxin and sanitary closures, which restricts Elders from harvesting what was formerly a mainstay of their diet along the eastern side of the Strait of Georgia.
- Aquatic plants (including attached and detached kelp and seaweeds) may be harvested for domestic purposes in the Tsawwassen Fishing Area at any time of day or year. These plants are specifically defined in the TFNFA as all benthic and detached algae, brown algae, red algae, green algae, golden algae and phytoplankton, and all marine and freshwater flowering plants, ferns and mosses, growing in water or soils that are saturated during most of the growing season (see “Gathering” section, below). Harvesting of these plants has not occurred since the TFNFA came into effect.
- Tsawwassen have previously reported that bulrushes have been harvested for basketry, and also for their medicinal properties. Tsawwassen members have also previously reported that at one time, seaweed grew “all over” and would be, along with sea asparagus, harvested “all along the shoreline” of Tsawwassen’s main community, although there is currently little to none reportedly left in these areas.

- Marine mammals, including porpoise, seals, and sea lions, were once harvested by the Tsawwassen within the mouth and estuary of the Fraser River. These marine animals (with the exception of porpoise, a cetacean) fall within the meaning of fish under the TFNFA. Tsawwassen have indicated that the community does not currently harvest marine mammals and that there is no desire to harvest marine mammals; however, they remain culturally important to the community.

3.1.2 Hunting/Trapping

- The extent of the Tsawwassen Wildlife Harvest Area and Tsawwassen Migratory Bird Harvest Area is the same as the Tsawwassen Territory, which overlaps the Project area. Specific species and harvesting sites (except Burns Bog for wildlife) are not identified in the TFNFA; however, locations near the Project area have been previously identified as preferred wildlife and migratory bird harvesting areas, particularly for deer, beaver, ducks, and geese. These locations include the south side of Lulu Island, the small islands, sloughs, marshes, and tidal flats of the Lower Fraser River, as well as the tidal flats at Boundary Bay.
- Wildlife, as defined under the TFNFA, includes all vertebrate and invertebrate animals, including mammals, birds, reptiles, and amphibians, and the eggs, juvenile stages, and adult stages of these animals. The definition excludes fish (see previous section) and migratory birds. Migratory birds, under the TFNFA, means birds, as defined under federal law enacted further to international conventions, and includes their eggs.
- The Tsawwassen’s rights to harvest wildlife and migratory birds allows designated members to harvest wildlife and migratory bird resources for domestic purposes and to trade or barter wildlife, wildlife parts, and migratory birds among themselves or with other Aboriginal people resident in BC. Harvested wildlife, wildlife parts (including meat and furs), migratory birds, and inedible migratory bird by-products (including down) may also be sold if the sale is permitted by federal, provincial, and Tsawwassen law. Wildlife and migratory bird harvesting rights may be exercised on private land (with the owner’s permission) and, in the case of migratory birds, within National Wildlife Areas (with Canada’s permission). With respect to wildlife harvesting specifically, the TFNFA acknowledges the “limited existing opportunity to harvest Wildlife and the likely future diminution or loss of any meaningful opportunity to harvest Wildlife in the Tsawwassen Wildlife Harvest Area”.
- At present, Tsawwassen is not harvesting any wildlife or migratory bird species for which a conservation risk has been identified. Harvesting of migratory birds is permitted throughout the year.

- Tsawwassen hunters have previously described locations throughout their traditional territory as preferred harvesting areas for wildfowl, including all of what are now Tsawwassen Lands and nearby fields, the shoreline from west of the Roberts Bank causeway up to and including Brunswick Point, and areas in and around Westham Island. Species harvested in the past include mallards, snow geese, and brant along the foreshore, and pintails, teals and wigeons in the back fields. Pheasants were previously taken “all over”, and quail was also eaten. Other species identified as valuable are gadwall, goldeneye, bufflehead, and canvasback ducks; as well as Canada geese, gulls, and songbirds.
- Tsawwassen explain that birds are no longer as abundant as they once were, with some species, such as the pheasant, now scarcely found and others, such as geese, preferring Boundary Bay over Roberts Bank to nest.
- Ducks and geese remain an important winter food and source of feathers, used for ceremonial purposes. Tsawwassen report the number of hunters has diminished and along with it the opportunities for transference of knowledge to youth.
- Tsawwassen explain deer and bear were once hunted from Point Roberts through Tsawwassen to Burns Bog, as well as on the Gulf Islands. Members had traplines for muskrat, otters, beaver, raccoon and rabbits from present-day Tsawwassen Lands to Westham Island. Currently, they pursue large game (e.g., deer and elk), in areas far removed from their Lands. Although they did not report current hunting or trapping of small animals, they did note there are fewer reporting requirements for small game harvesting than for other species, and thus some degree of harvesting is probable.

3.1.3 Gathering

- Plants, as defined under the TFNFA, includes all flora and fungi but does not include aquatic plants (included in the definition for fish) or trees except for their bark, branches and roots.
- Tsawwassen’s right to harvest plants allows members to harvest plants for domestic purposes and includes the right to trade or barter plants among themselves or with other Aboriginal people resident in BC, as well as to exchange regalia or traditional or artistic objects made of plants among themselves or with other Coast Salish people for ceremonial purposes.
- There are four Tsawwassen Plant Gathering Areas designated under the TFNFA, two of which are located considerably north of the Project area. The two areas located near the Project area are:
 - the South Arm Marshes Wildlife Management Area, immediately downstream of the Highway 99 Fraser River crossing; and
 - Provincial Crown Land within the Burns Bog Ecological Conservancy Area, north of the easternmost extent of the Project footprint.

- Specific species harvested in these areas are not identified in the TFNFA; however, plant species and timber resources in the Project area include *quxmin*, salal, bog blueberries, Indian hemp, cattails and rushes, St. John’s wort, western red cedar, Douglas fir, western hemlock, western yew, black cottonwood, red-osier dogwood, and red alder.
- Other plant species identified as important by Tsawwassen Elders or resource users include wild berries (e.g. blackberries, huckleberries, salmonberries, strawberries, snowberries, boysenberries, loganberries, raspberries, black caps, red caps), cherries, crabapples, wild onion, wild mint, rhubarb, Labrador tea, wild rose, thistle, Indian Consumption Plant, yellow or curly dock, devil’s club, ferns, cascara bark, barberry bark, and stinging nettle.
- Traditional timber resources also include cherry, hazelnut, and willow trees; driftwood was also collected from the beach to smoke fish, but no community smokehouses remain.
- Tsawwassen have reported that plants are mainly gathered in and around Tsawwassen Lands (where still available), and plans are currently underway to resume harvesting in designated areas and to support the transfer of traditional plant use knowledge to Tsawwassen youth.

3.1.4 Archaeology and Cultural Heritage Interests

- Tsawwassen’s right to practice their culture, as well as use of the Hən̓q̓əmi̓n̓əm̓ language, is identified in the TFNFA. Several Hən̓q̓əmi̓n̓əm̓ place names for important heritage sites in the vicinity of the Project area are also identified in the TFNFA, including the following:
 - ʔ'eqtinəs (or Tl'ektines), identified in the TFNFA as DgRs-17, which places it slightly upstream of the Project area on the north shore of the South Arm of the Fraser River;
 - čičiləxwqən (Ladner Landing, DgRs-41), downstream of the Project area; and
 - Xwlic'əm (Brunswick Point on Canoe Pass, DgRs-35), also downstream of the Project area.
- Tsawwassen emphasize the importance of the Fraser River to their members for fishing, transportation, recreation, and cultural purposes. Tsawwassen stress the importance of their continued ability to fish, along with and the significance of fishing and associated activities to their community’s culture and economy. Some traditional activities, such as spending time with Elders in the smokehouse, no longer occur, as the last smokehouse was demolished when Highway 17 was expanded.

- Tsawwassen report that disturbance of fish and fish habitat (e.g., sturgeon) as well as water quality are their biggest concerns. Tsawwassen Elders report changes to the foreshore north and south of their Lands (i.e., “our little beach”), to which they attribute access difficulties, decreases in species abundance, and compromised quality of resources, especially shellfish and crab. Accordingly, they say they have also experienced the loss of important and organic means for community gathering and socializing at this important location (i.e., *sćəwə’əən* and *ća yəm*), both internally and with other nations with whom they have traditionally traded. This has also meant the loss of opportunities to pass down traditions related to the use of the beachfront to their youth.
- Tsawwassen explain that participation in fishing, an integral element of Tsawwassen culture, is decreasing, due to diminishing stocks, increasing harvesting restrictions, and higher costs related to having to travel farther to harvest traditional resources.

3.1.5 Other Related Interests

- Tsawwassen identify the lack of a local dock as contributing to higher costs. While public docks are available at the southeastern end of B.C. Ferries Terminal and at Brunswick Point in Canoe Passage, these docks are reportedly very busy, particularly in the summer months.
- Further, Tsawwassen report that physical access to Fraser River fisheries has changed. Chilukthan Slough, which at one time ran between Roberts Bank and the Fraser River, from north of Tsawwassen Lands to the Ladner area, was considered Tsawwassen’s “short cut” to the Fraser River; the slough was filled along ago as a result of farm development, and was described as a “huge” loss by Tsawwassen Elders. Access to the Fraser River by water now involves a longer route around the existing Roberts Bank terminals and B.C. Ferries Terminal.
- For canoe journeys, Tsawwassen members must navigate as close as possible to the terminals to and from the river to avoid shipping lanes, large vessel traffic, and shallow waters.
- Tsawwassen members report that the changes to current flows and sediment build up between the Roberts Bank terminals and causeway to Westham Island are the reason that Canoe Passage, an important fishing area and travel corridor to and from the South Arm of the Fraser River, has become difficult to transit other than at high tide. They report Canoe Passage has become narrower, which means that fewer fishing vessels are able to harvest in the area at any one time.

4.0 Potential Effects

This section provides a summary of the methodology used to identify potential adverse effects of the proposed Project on the exercise of Aboriginal Interests by Aboriginal Groups during Project construction and operation, followed by a summary of potential effects on Tsawwassen's Aboriginal Interests, specifically. For a more detailed description, refer to **Section 10.1.3.3.**

Potential Effects.

4.1 Methodology for Identification of Potential Effects

The first step in the effects assessment on Aboriginal interests was the identification of potential adverse effects on traditional use activities and related interests as a result of Project construction or operation. To evaluate these potential adverse effects, the findings of the following Valued Component (VC) chapters in Part B of the Application were considered, including identified mitigation measures, residual effects, cumulative effects and follow up strategies:

- **Section 4.4 Fish and Fish Habitat**
- **Section 4.6 Marine Mammals**
- **Section 4.7 Vegetation**
- **Section 4.8 Terrestrial Wildlife**
- **Section 5.2 Marine Use**
- **Section 5.3 Land Use**
- **Section 5.5 Visual Quality**
- **Section 6.1 Heritage Resources**
- **Section 7.1 Human Health**

The findings of the following Intermediate Component (IC) chapters were also considered in the assessment:

- **Section 4.1 River Hydraulics and River Morphology**
- **Section 4.2 Sediment and Water Quality**
- **Section 4.9 Air Quality**
- **Section 4.10 Atmospheric Noise**

The assessment of potential adverse effects of the Project on the exercise of Aboriginal Interests, including measures to address those effects, are presented in **Section 10.1.3.3** through **Section 10.1.3.5**, and largely applies the same methods used in Part B of the Application for the IC and VC assessments, as outlined in **Section 3.0 Assessment Methodology**.

In addition to information from the VC and IC assessments that support the assessment of potential effects on Aboriginal Interests, information from a Health Impact Assessment (HIA) undertaken to support Project planning, including mitigation recommendations, has been integrated into the assessment of potential effects on Aboriginal Interests. The HIA for the Project can be found at <https://engage.gov.bc.ca/masseytunnel>. A summary of the key findings is provided in **Section 7.2 Health Impact Assessment**.

4.2 Selection of Indicators

Four parameters were chosen as indicators to understand and evaluate potential Project-related effects on the exercise of Aboriginal Interests. The rationale for their selection is presented in the following table.

Table 2 Indicators for the Aboriginal Interests Assessment

| Indicator | Rationale for Selection |
|---|---|
| Access to preferred locations for the exercise of Aboriginal Interests | Project components or activities could result in changes in access to or patterns of travel between traditional use locations on land or water |
| Availability of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in distribution or movement, relative abundance, or habitat area or composition of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in the real or perceived quality of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests | Project components or activities could result in: (1) direct sensory disturbance to traditional users (e.g., from noise, vibration); and/or (2) indirect changes to cultural practices, customs or traditions – i.e., cultural heritage or the expression and transfer of cultural values or ways of knowing (e.g., language, laws/governance, stories, spiritual beliefs) – tied to the cultural landscape or to the traditional use of specific traditional use locations or resources within that landscape. |

Potential adverse effects on the indicators noted above were analyzed in terms of the type and level of effect that Project components and activities may be expected to have on the exercise of Aboriginal Interests.

For the purposes of this assessment, no effect was understood to mean that no interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests would be expected. Where it was determined that an interaction, and potential effect, could occur, the following definitions were used to guide the characterization of the effect as negligible or measurable:

- Negligible – An interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests may occur, but modifications to the use of preferred options would not be expected.
- Measurable – Modifications to the exercise of Aboriginal Interests at preferred locations or in relation to preferred resources may be needed, and may be considered to be:
 - Minor (minimal or temporary modifications may be required to use preferred options),
 - Moderate (more frequent or longer term modifications may be required to use preferred options), or
 - Serious (permanent or indefinite modifications may be required potentially resulting in the loss of preferred options).

4.3 Identified Potential Effects

As noted above, the first step in evaluating potential adverse effects on Aboriginal Interests was a consideration of the findings for relevant Part B VCs, including identified mitigation measures, residual effects, cumulative effects and follow up strategies. The residual effects with the potential to result in an adverse effect on Aboriginal Interests are then carried forward in the assessment. Using the four indicators noted in the previous section, the potential Project-related effects and level of effect predicted in relation to Tsawwassen's exercise of Aboriginal Interests remaining after Part B mitigation are as follows:

Table 3 Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|---|--------------|------------|------------|------------|---|
| | Negligible | Measurable | Negligible | Measurable | |
| River locations for traditional use as a result of changes to physical characteristics of these locations | ✓ | | ✓ | | |
| Instream locations for traditional use | | ✓ | | ✓ | Construction - Potential temporary direct (minor to moderate) effect on access related to instream construction activities Operation - Potential indirect (minor to moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses |
| Upland locations for traditional use | ✓ | | ✓ | | |

Table 4 Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |

| Cultural landscape | | ✓ | | ✓ | Construction - Potential temporary indirect (minor to moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance Operation - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses |

4.4 Potential Project-Related Effects on Tsawwassen's Aboriginal Interests

Using the methodology presented in **Section 10.1.3.3 Potential Effects**, Table 7 provides the potential incremental Project-related effects, following mitigation of Project-related effects on Part B VCs and ICs as described in Part B, related to Tsawwassen's Aboriginal Interests as summarized in Existing Conditions were identified for Project Construction and Operation. A discussion of potential Project-related effects on fishing, hunting/trapping, gathering and archaeology and cultural heritage follows the table.

Table 7 Summary of Potential Project-Related Effects

| Indicator | Potential Project-related Effect |
|--|---|
| Project Construction | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • Potential temporary direct (minor to moderate) effect on access related to instream construction activities |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • For instream locations for traditional use, potential temporary indirect (minor to moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses dependent on that access • Potential temporary direct (minor to moderate) effect on quality of experience related to construction-related noise • Potential temporary indirect (minor to moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance |
| Project Operation | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified |
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • Potential indirect (minor to moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses • Potential permanent direct (minor to moderate) effect on quality of experience related to traffic noise • Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses |

4.5 Fishing

The Tsawwassen Fishing Area, which applies to fish and aquatic plants but excludes intertidal bivalves includes the waters of the Main Arm of the Fraser River westerly of the power lines downstream of the Port Mann Bridge, the waters of the North Arm of the Fraser River from the junction of the Main Arm downstream to the Arthur Laing Bridge, the Middle Arm of the Fraser River, the South Arm of the Fraser River, and parts of the waters of the Strait of Georgia and Boundary Bay. Tsawwassen report that they actively fish in the South Arm of the Fraser River and within the Project area.

The proposed Project has the potential to affect fishing practices through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred fishing locations by Tsawwassen, as a result of changes in river hydraulics or morphology, are expected to be negligible before mitigation. Potential changes in access to instream locations for fishing by Tsawwassen during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to fishing locations by Tsawwassen from instream construction activities are expected to be negligible. While it is acknowledged that Tsawwassen has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Mitigation measures identified in the fish and fish habitat assessment to address Project-related effects on fish are expected to be effective at addressing potential effects on the availability of fishing resources preferred by Tsawwassen. Further, as residual effects on fish identified in the fish and fish habitat assessment are not anticipated to affect population integrity, potential residual effects as a result of Project construction activities, would not be expected to measurably affect the availability of preferred fish resources.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of fishing resources preferred by Tsawwassen; therefore, Potential Project-related effects on Tsawwassen fishing would be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when fishing are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** are expected to largely address a potential Project-related effect to the quality of experience while fishing. At preferred fishing locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Tsawwassen.

Section 5.5 Visual Quality predicts that residual effects to visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Tsawwassen is fishing. As this landscape has been previously modified, the potential Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Tsawwassen's Aboriginal Interests related to fishing are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.6 Hunting/Trapping

The extent of the Tsawwassen Wildlife Harvest Area and Tsawwassen Migratory Bird Harvest Area is the same as the Tsawwassen Territory, which overlaps the Project area. Specific species and harvesting sites (except Burns Bog for wildlife) are not identified in the TFNFA; however, locations near the Project area have been previously identified as preferred wildlife and migratory bird harvesting areas, particularly for deer, beaver, ducks, and geese. These locations include the south side of Lulu Island, the small islands, sloughs, marshes, and tidal flats of the Lower Fraser River, as well as the tidal flats at Boundary Bay.

The proposed Project has the potential to affect hunting and trapping through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred hunting and trapping locations by Tsawwassen as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for hunting and trapping by Tsawwassen during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to hunting and trapping locations by Tsawwassen from instream construction activities, are expected to be negligible. While it is acknowledged that Tsawwassen has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for hunting and trapping by Tsawwassen resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with hunting and trapping locations.

Mitigation measures identified in the marine mammal and terrestrial wildlife assessments are expected to be effective at addressing potential effects on the availability of hunting and trapping resources preferred by Tsawwassen. Therefore, Project-related effects on hunting and trapping related to potential changes in the availability of resources would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for hunting and trapping by Tsawwassen; therefore, Potential Project-related effects on Tsawwassen fishing would be expected to be negligible.

Project operation is not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when hunting and trapping are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** to address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while hunting and trapping. At preferred hunting and trapping locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Tsawwassen.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Tsawwassen is hunting and trapping. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Tsawwassen's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.7 Gathering

Plants, as defined under the TFNFA, includes all flora and fungi but does not include aquatic plants, which are included in the definition for fish or trees except for their bark, branches and roots. There are four Tsawwassen Plant Gathering Areas designated under the TFNFA, two of which are located considerably north of the Project area. The two areas located near the Project area are:

- the South Arm Marshes Wildlife Management Area, immediately downstream of the Highway 99 Fraser River crossing; and
- Provincial Crown Land within the Burns Bog Ecological Conservancy Area, north of the easternmost extent of the Project footprint.

However, the specific species harvested in these areas are not identified in the TFNFA.

The proposed Project has the potential to affect gathering through changes in access to preferred locations, changes in availability of preferred resources, changes in quality of preferred resources and changes in quality of experience when gathering.

Potential changes in access to preferred gathering locations by Tsawwassen as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for gathering by Tsawwassen during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to gathering locations by Tsawwassen from instream construction activities, are expected to be negligible. While it is acknowledged that Tsawwassen has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for gathering by Tsawwassen resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with gathering locations.

Mitigation measures identified in the vegetation assessment to address Project-related effects on terrestrial vegetation are expected to be effective at addressing potential effects on the availability of resources for the exercise of Aboriginal Interests related to gathering. Therefore, Project-related effects on gathering related to potential changes in the availability of vegetation would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for gathering by Tsawwassen; therefore, Potential Project-related effects on gathering related to potential changes in the quality of resources would therefore be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when gathering are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while gathering. At preferred gathering locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Tsawwassen.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Tsawwassen is gathering. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Tsawwassen's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.8 Archaeology and Cultural Heritage Interests

Tsawwassen's right to practice their culture, as well as use of the Hən̓q̓əmiñəm language, is identified in the TFNFA. Several Hən̓q̓əmiñəm place names for important heritage sites in the vicinity of the Project area are also identified in the TFNFA.

The proposed Project has the potential to affect Tsawwassen's Aboriginal Interests related to archaeology and cultural heritage through changes in access to preferred locations and changes in quality of experience.

Potential changes in access to locations related to Tsawwassen's archaeological and cultural heritage interests as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations related to Tsawwassen's interests related to archaeology and cultural heritage during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to locations related to Tsawwassen's archaeological and cultural heritage interests from instream construction activities are expected to be negligible. While it is acknowledged that Tsawwassen has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations related to Tsawwassen's archaeological and cultural heritage interests resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and not expected to overlap with locations related to Tsawwassen's archaeological and cultural heritage interests.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** would also be expected to address the potential Project-related effect to the quality of experience while undertaking activities related to cultural heritage. At locations related to Tsawwassen's archaeological and cultural heritage interests that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Tsawwassen.

As reported in **Section 6.1 Heritage Resources**, no archaeological or historical sites were identified within the Project area during fieldwork; however, there may be other locations with intangible cultural value or meaning to Tsawwassen (e.g., spiritual or storied sites, named places) potentially affected by the Project. In addition, physical alterations to the landscape may affect archaeological or historical sites, and how this landscape is experienced culturally.

As a result, mitigation measures proposed in Part B are not expected to address a potential incremental and permanent Project-related effect tied to Tsawwassen's Aboriginal Interests related to archaeology and cultural heritage that may be associated with the introduction of a new prominent feature to the cultural landscape. As this landscape has been previously modified by anthropogenic changes, the potential incremental Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal, but permanently disruptive for Tsawwassen, who have identified a historical connection to, and continued or desired use of, sites or places that help define the cultural landscape in the Project area.

Additional mitigation to address this potential incremental effect that is not otherwise addressed in the Application is proposed in **Section 10.1.3.4** and summarized below under Mitigation.

5.0 Mitigation

This section provides a summary of mitigation measures identified to address potential Project-related effects on the exercise of Aboriginal Interests by Tsawwassen. For a more detailed discussion, refer to **Section 10.1.3.4 Mitigation**.

Mitigation measures identified for the relevant VCs and ICs in Part B of the Application were reviewed to assess their effectiveness at addressing potential Project-related effects on the exercise of Aboriginal Interests related to those VCs. Examples of mitigation that are proposed in the Application to address potential effects on VCs and ICs, with the potential to result in an effect on Aboriginal Interests, include:

- Avoiding fisheries sensitive timing windows during key Project activities.
- Developing a Marine Access Management Plan to ensure marine use activities, including those supporting Aboriginal Interests, can continue during Project construction.
- Scheduling activities with the potential to generate underwater noise to avoid potential effects on marine mammals.
- Development and implementation of a Terrestrial Vegetation and Wildlife Management Plan with measures to minimize disturbance and loss of vegetation, prevent soil compaction, and minimize clearing in order to minimize effects on vegetation.

These measures are expected to be largely effective at avoiding, reducing, or otherwise managing potential Project-related effects on the exercise of Aboriginal Interests during Project construction and operation.

Recognizing some measurable effects on Tsawwassen's Aboriginal Interests could remain following the application of mitigation to address potential effects on the relevant VCs and ICs in Part B, the following additional measures have been identified to address such effects:

- Ongoing consultation with Tsawwassen regarding proposed measures, management plans, and monitoring programs related to intermediate components and valued components assessments; and
- Development of a Cultural Heritage Management Plan.

6.0 Residual Effects

With the implementation of mitigation measures identified in **Section 10.1.3.4** and summarized above, residual adverse effects of the proposed Project on the exercise of Aboriginal Interests are expected to be negligible (i.e., not measurable or detectable), and are not further assessed.

7.0 Summary and Conclusion

Part C of the Application builds on consultation undertaken to date to understand Tsawwassen's Aboriginal Interests and provides for an assessment of potential Project-related effects of the Project on Aboriginal Interests.

The Ministry began consultations with Tsawwassen prior to the submission of the Project Description, which is the end of the Initial Consultation Phase. Both EAO and the Ministry consulted with Tsawwassen during the Pre-Application Phase, which concluded with the submission of the Application. The main concerns expressed by Tsawwassen during consultations include:

- Recognition of Tsawwassen First Nation as a Treaty Nation and consultation must be undertaken as set out in the Tsawwassen First Nation Final Agreement;
- Potential effects to Tsawwassen First Nation's Fishing Right and Rights to Harvest Wildlife, Migratory Birds and Plants as set out in Tsawwassen First Nation Final Agreement;
- Potential effects on ability of Members to participate in commercial fisheries and/or as participants in the general commercial fishery;
- Potential effects on fish, wildlife, birds and plants and their habitats;

- Potential effects on ability to harvest fish, wildlife, birds and plants and on harvesting locations;
- Aboriginal participation and Project-related opportunities and importance of professional development and career planning in relation to career opportunities;
- Changes to river hydrology;
- Social effects of the Project on Tsawwassen 's ability to transfer knowledge, language and participate in socio-cultural practices;
- Use of Fraser River for traditional, recreational and cultural purposes and effects on movements and activities resulting from Tunnel decommissioning;
- Potential economic, cultural and health effects resulting from changes to quality and availability of natural resources for Tsawwassen and Aboriginal Groups' Tsawwassen engages with, now and into the future;
- Protection of archaeological and heritage resources, including intangible heritage sites and participation in archaeological fieldwork and review of archaeological draft reports;
- Construction environmental best management practices;
- Trend in development of the lower Fraser River;
- Adequacy of Environmental Assessment (EA) methodology to address social and cultural effects;
- EA Process for the Project and its associated timelines;
- Absence of a comprehensive study of cumulative effects on the Fraser River;
- Participation of federal government in EA;
- Concerns regarding spills and potential contamination;
- Effects on air quality resulting from increase in traffic volume due to the Project;
- Concerns related to dredging, potential for increased vessel traffic and larger vessels resulting from Tunnel decommissioning;
- Potential effects on flow rates after Tunnel removal; and
- Potential effects of run off and drainage along the highway corridor, including heavy metal transport from traffic to water and land, management of runoff from the bridge.

Based on information provided by Tsawwassen and other publicly-available sources, the Ministry developed a summary of past, present and desired future use of the proposed Project area and its surroundings for the purposes of fishing, hunting/trapping, gathering, archaeology and cultural heritage interests and other related interests. This summary indicates that Tsawwassen has, does and intends to continue to use the Fraser River for cultural purposes.

Relying first on the results of the effects assessments for related VCs and ICs in Part B, the assessment of potential effects of Tsawwassen's Aboriginal Interests considered four indicators:

1. Access to preferred locations for the exercise of Aboriginal Interests;
2. Availability of preferred resources for the exercise of Aboriginal Interests;
3. Quality of preferred resources for the exercise of Aboriginal Interests; and
4. Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests.

As reviewed in **Section 10.1.3.3** and **Section 10.1.3.4**, the mitigation measures, management plans, and monitoring programs identified in Part B of the Application for VCs or ICs linked to the exercise of Aboriginal Interests are expected to be largely effective at addressing the incremental Project-related effects noted above on the exercise of Aboriginal Interests by Tsawwassen, except in the following potentially measurable cases:

- Project Construction:
 - Potential temporary direct (minor to moderate) effect on access related to instream construction activities and a potential temporary indirect (minor to moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses dependent on that access
 - Potential temporary direct (minor to moderate) effect on quality of experience related to construction-related noise and a potential temporary indirect (minor to moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance
- Project Operation:
 - Potential permanent direct (minor to moderate) effect on quality of experience related to traffic noise and a potential indirect (minor to moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses
 - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses

The following additional measures have been identified to address the above-noted effects:

- Ongoing consultation with Tsawwassen regarding proposed measures, management plans, and monitoring programs related to VCs and ICs; and
- Development of a Cultural Heritage Management Plan.

With the implementation of mitigation proposed to address potential effects on VCs and ICs, as well as additional mitigation proposed to address potential residual effects on Aboriginal Interests, no effects on the exercise of Aboriginal Interests by Tsawwassen, as a result of the Project, are expected.

Note: Concerns listed in this table include those outlined in the GMT Project Impact Study prepared and submitted by Tsawwassen First Nation.

| ENVIRONMENTAL ASSESSMENT PROCESS | | | |
|---|---|-----------------|--------------------------------|
| <p>An environmental assessment of the Project is required under the B.C. <i>Environmental Assessment Act</i> (B.C. <i>EAA</i>), S.B.C. 2002, c. 43, and permits to construct and operate can only be received once the environmental assessment process is complete and an Environmental Assessment Certificate (EAC) has been issued. If the Project is approved, an EAC will be awarded to and held by the Ministry. The Reviewable Projects Regulation B.C. Reg. 370/2002 under the B.C. <i>EAA</i> sets out the criteria for reviewable projects.</p> <p>On December 16, 2015, the B.C. Environmental Assessment Office (EAO) issued a Section 10(1)(c) Order confirming that the Project is a reviewable project pursuant to the B.C. <i>EAA</i>, and that it requires an EAC.</p> <p>The Project as proposed is not subject to review under the <i>Canadian Environmental Assessment Act, 2012</i>, S.C. 2012, c. 19, s. 52, since it does not meet the definition of a physical activity under the Schedule of Physical Activities in the Regulations Designating Physical Activities SOR/2012-147.</p> <p>EAO is a neutral agency that manages the review of proposed major projects in British Columbia, as required by the <i>Environmental Assessment Act</i>.</p> | | | |

| TSAWWASSEN TREATY AND OTHER INTERESTS | | | |
|--|--|---------------------------------|--|
| <p>The Tsawwassen First Nation Final Agreement (TFNFA) secures harvesting rights to the Tsawwassen First Nation in areas located within Tsawwassen Territory, which is defined as the area of land that Tsawwassen First Nation identified in its Statement of Intent to the British Columbia Treaty Commission, and included as a map in Appendix A to the agreement (TFN et al. 2009b). This territory extends from the southern Gulf Islands to the area around Pitt Lake. Rights under the TFNFA are limited by measures necessary for conservation, public health, or public safety (TFN et al. 2009a).</p> <p>The Project area lies within Tsawwassen Territory, and is situated in or near several harvesting areas defined in the TFNFA relating to fishing, wildlife and migratory bird harvesting, and plant gathering (TFN et al. 2009a,b).</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| <p>Obligations to Tsawwassen as a Treaty Nation must be recognized and consultation must be undertaken as set out in the Tsawwassen Final Agreement</p> | <p>The Ministry recognizes and respects the obligations to Tsawwassen as a Treaty Nation and will continue to undertake consultation according to the requirements outlined in the Tsawwassen Final Agreement. Potential effects to Tsawwassen treaty rights and other interests are discussed in Part C of the Application.</p> | <p>Ongoing</p> | <p>Ongoing consultation</p> |
| <p>Potential effects to Tsawwassen Fishing Right: Project activities may affect ability of Members to participate in commercial fisheries and/or as participants in the general commercial fishery Direct impacts on fish or fish habitat and impact on water quality could affect fisheries resources Impact on fishing locations Interference or displacement of fishing opportunities within the Project area</p> | <p>The Ministry will work closely with Tsawwassen to ensure negative effects are avoided. Potential interference with Tsawwassen fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Sections 4.4.4 (Fish and Fish Habitat Mitigation Measures) and 5.2.4 (Marine Use Mitigation Measures)</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|--|
| <p>Potential effects to Tsawwassen Right to Harvest Wildlife: Spills contaminating habitat, directly killing or poisoning animals. Human presence and activities can lead to safety concerns related to the use of firearms for hunting wildlife resulting in loss of opportunity for TFN Members to exercise treaty rights. Increased wildlife mortality as a result of vehicle collisions and collision with infrastructure. Loss or restriction of harvesting activities over the status quo. Disturbance or displacement of species. Loss or degradation of wildlife habitat.</p> | <p>Tsawwassen’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife), residual effects on the exercise of Aboriginal Interests by Tsawwassen as a result of the Project are not expected.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife)</p> |
| <p>Potential effects to Tsawwassen’s Right to Harvest Migratory Birds: Increased wildlife mortality as a result of vehicle collisions and collision with infrastructure. Loss or restriction of harvesting activities over the status quo. Disturbance or displacement of migratory birds Loss or degradation of bird habitat. Human presence and activities can lead to safety concerns related to the use of firearms for hunting migratory birds resulting in loss of opportunity for members to exercise treaty rights.</p> | <p>Tsawwassen’s rights to harvest terrestrial wildlife within the Project area are addressed in Section 4.8 (Terrestrial Wildlife) of the Application. With the implementation of mitigation measures, residual effects on the exercise of Aboriginal Interests by Tsawwassen as a result of the Project are not expected.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4 (Terrestrial Wildlife Mitigation Measures)</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Potential effects to Tsawwassen’s Right to Harvest Plants: Changes in river hydrology affecting shorelines, tidal wetlands, mudflats, drainage channel and uplands of the south arm marshes wildlife management area and adjoining areas that may lead to changes impacting members’ ability to gather and use plants. Loss or degradation of plant harvesting areas, including damage by invasive plants. Human activities directly killing biota (collisions, pile driving and dredging). Spills contaminating habitat, directly killing or poisoning plants.</p> | <p>Tsawwassen’s rights to harvest vegetation within the Project area are addressed in Section 4.7 (Vegetation) of the Application. With the implementation of mitigation measures, residual effects on the exercise of Aboriginal Interests by Tsawwassen as a result of the Project are not expected.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.7.4 (Vegetation Mitigation Measures)</p> |
| <p>Need for Proponent to understand that Tsawwassen’s Treaty rights are not limited to how the right is currently being exercised. Instead, impacts can include the potential loss of future opportunities for activities that were either not always practiced historically or that may or may not be currently being exercised.</p> | <p>Noted and reflected in Part C of the Application.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation</p> |

| | <p>outlined in Part B of the Application. Other Projects that are considered in the assessment of Project-related cumulative effects are also listed.</p> <p>While the Ministry acknowledges that Tsawwassen is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project.</p> | | |

| ABORIGINAL CONSULTATION | | | |
|---|--|---------------|---|
| <p>Aboriginal Interests, defined as asserted or determined Aboriginal rights, including title, and treaty rights, are known to overlap or lie in the vicinity of the Project corridor. Potential adverse effects on the exercise of Aboriginal Interests as a result of Project construction and operation have been identified.</p> <p>Mitigation measures to address potential Project-related effects on intermediate components (ICs) and valued components (VCs) associated with the exercise of Aboriginal Interests are expected to be effective. With the application of mitigation, potential effects on the exercise of Aboriginal Interests are predicted to be negligible except in specific cases during Project construction and operation. To address potential effects during Project construction and operation, the development of an Archaeological and Heritage Resources Management Plan is proposed.</p> <p>In addition to mitigation measures proposed to address potential effects on ICs and VCs, ongoing engagement between the Ministry and Schedule B Aboriginal Groups will be undertaken. Such engagement will take place during Application Review and, if the Project is approved, following the issuance of an Environmental Assessment Certificate (EAC). Engagement will involve consultation on management plans and monitoring programs, related to the exercise of Aboriginal Interests.</p> <p>Ongoing engagement is also proposed to address other matters of environmental, economic, social, heritage, and health concern raised Aboriginal Groups during the pre-Application period. With this ongoing engagement, residual effects on the exercise of Aboriginal Interests or other matters of concern as a result of the Project are not expected.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Capacity funding to facilitate participation in the Project review process. | Tsawwassen received funding for the Pre-Application Phase. The Ministry will provide further funding for the Application Review Phase. | Addressed | Consultation regarding funding for the Application Review Phase |
| Importance of ensuring appropriate use of information shared by Aboriginal Groups' as it relates to confidentiality and dissemination. | The Ministry understands and respects that certain information shared by Tsawwassen may be considered confidential. The Ministry is subject to the provisions of the Freedom of Information and Protection of Privacy Act. Subject to the requirements of applicable laws, the Ministry will respect Tsawwassen requests to keep information confidential. | Addressed | Appropriate use of confidential information |
| Funding for Project Related Study | Tsawwassen received funding for a Project related Study. | Addressed | None |

ABORIGINAL PARTICIPATION AND PROJECT-RELATED OPPORTUNITIES

The Ministry is actively exploring opportunities to provide benefits, economic and non-economic, to Aboriginal Groups that are directly affected by the Project. Opportunities include employment, training, and contracting as well as participation in environmental enhancement and other components of the Project.

Prior to the Pre-Application Phase of the Project, the Ministry worked with Schedule B Aboriginal Groups to determine appropriate tools to support consultation. Consultation activities were based on the specific needs and preferences of these Aboriginal Groups and the Consultation Plan included individualized plans that were co-developed and reviewed.

The Project's Aboriginal Consultation Plan has been developed in consultation with Schedule B Aboriginal Groups, in order to meet the Aboriginal consultation requirements as delegated by EAO and to maintain and, where possible, enhance positive working relationships between the Ministry and the respective Aboriginal Groups.

The objectives and requirements of the Aboriginal Consultation Plan are to:

- Provide relevant Project-related information in a timely and effective manner that supports an understanding of the nature of the Project and its potential adverse effects on Aboriginal Interests
- Plan and implement mutually acceptable consultation activities that support effective participation of Aboriginal communities in the EA as well as related regulatory and permitting processes
- Establish and maintain dialogue throughout the EA as a means of providing opportunities to respond to outstanding concerns
- Provide opportunities for Aboriginal Groups to share views of the Project with the Ministry and EAO within reasonable timeframes
- Provide opportunities for Aboriginal Groups to identify potential adverse effects of the proposed Project on Aboriginal Interests, including cumulative effects and, to the extent appropriate, develop ways to mitigate or otherwise accommodate potential adverse effects
- Involve Aboriginal Groups, where possible, in relevant studies including, but not limited to, archaeological fieldwork.
- Incorporate community and traditional knowledge in Project components

Document and report to EAO on the Ministry's Aboriginal consultation program at times specified by EAO

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------|--|
| Opportunities for cultural recognition and naming | The Ministry is exploring opportunities for cultural recognition and naming and will work with Tsawwassen on this matter. | Ongoing | Discussion with Tsawwassen to explore opportunities related to cultural recognition and naming, art and interpretive signage |
| Project-related employment, training, contracting, and economic development opportunities Adequate training time to take full advantage of potential future Project work activities | The Ministry is committed to working with Tsawwassen to identify potential opportunities to benefit from the Project. The Ministry acknowledges that Tsawwassen want to prepare their membership for employment opportunities and will work with Tsawwassen to identify ways to support community preparedness. | Ongoing | The Ministry will share information as it becomes available to support community preparedness and welcomes input from Aboriginal Groups on the type of information that would be useful. |
| Interest in revenue sharing opportunities from tolling | Revenue from tolling is only used to defray the costs of designing, constructing, operating and maintaining highways. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application. | | None |

4.1 RIVER HYDRAULICS

The proposed bridge will have a clear-span, which eliminates potential changes to river hydraulics or river morphology resulting from the new structure. The Fraser River South Arm is dynamic with scour in the order of several metres during freshet and migrating sand dunes with heights of up to four metres. Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. Tunnel removal is expected to result in temporary bed lowering between the Tunnel and Lulu Island-Delta water main; however, no permanent effect on the Lulu Island-Delta watermain is expected.

Effects

A negligible effect to access to river locations for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of river locations has been determined.

Mitigation

Development of a mitigation plan to ensure protection to the Lulu-island-Delta water main.

Monitor the riverbed within 100 metres upstream and downstream of the watermain.

Stockpile appropriately-sized rock near the Project site, for priority scour protection repairs at the water main crossing.

Establish on-call contracts with a qualified registered professional and a qualified marine contractor prior to Tunnel removal, to ensure that scour protection repairs can be designed and implemented on short notice

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |

| <p>Change in flow rates after Tunnel removal</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects to river hydraulics and river morphology within the Fraser River South Arm.</p> <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. River Hydraulics and River Morphology are addressed in Section 4.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4 (River Hydraulics Mitigation Measures)</p> |
| <p>Potential effect of removing the Tunnel on marshes along the river</p> | <p>Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary march, that occur in the vicinity of the Project.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4 (River Hydraulics Mitigation Measures)</p> |

4.2 SEDIMENT AND WATER QUALITY

The proposed bridge will have a clear-span, which reduces potential effects to sediment and water quality within the Fraser River South Arm. During Tunnel decommissioning, a minor, temporary increase in turbidity, as compared with baseline conditions, is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.

Project activities undertaken in the upland ditch systems will follow Standards and Best Practices for Instream Works.

Effects

A negligible effect on quality of water used for cultural purposes has been determined.

A negligible effect on quality of experience tied to use of water for cultural purposes has been determined.

Mitigation

Avoid effects through Project design.

Incorporate a stormwater collection and distribution system (stormwater detention ponds and biofiltration swales) into bridge design that will convey and discharge stormwater runoff to appropriate upland infrastructure for proper treatment.

Develop Construction Environmental Management and Operational Environmental Management plans.

Control suspended sediment during Tunnel decommissioning. Employment of construction methods that minimize levels of Project-induced turbidity. Use spoil barges equipped with sediment containment system (filter cloth, concrete lock blocks, straw bales) to transport removed material off-site.

Control suspended sediment during Project construction in and adjacent to Deas and Green Sloughs. Use of sediment control measures such as turbidity curtains and de-watered cofferdams.

Monitor water quality during construction.

Use timing windows for undertaking in-stream works.

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology or sediment and water quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|------------------|---|
| <p>Potential effects of run off and drainage</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected. Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in Section 4.2.4 (sediment and water quality mitigation measures)</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|------------------|---|
| <p>Management of run off from the bridge</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. 4.4 FISH AND FISH HABITAT

The proposed bridge will have a clear span over the Fraser River South Arm and Deas Slough, avoiding or minimizing Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Given the disturbed nature of much of the Project alignment, re-vegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by improvements to local water quality; removal of non-native species; and replanting with species that provide habitat value for fish and wildlife.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

Mitigation

Avoid effects through Project design.

Apply best management and environmental management practices.

Develop Construction Environmental Management and Operational Environmental Management plans.

Use timing windows for undertaking in-stream works.

Erosion and sediment control.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term potential of physical injury or mortality to fish through crushing or entrainment during the construction period.

No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|--------------------------|---|
| Potential effects to Tsawwassen Right to Harvest | <p>Tsawwassen's rights to harvest within the Project area are addressed in Part C of the Application.</p> <p>With the implementation of mitigation measures in Section 4.4 (Fish and Fish Habitat), residual effects on the exercise of Aboriginal Interests by Tsawwassen as a result of the Project are not expected.</p> | Addressed in Application | Implementation of mitigation measures in Section 4.4 (Fish and Fish Habitat) |
| Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon. Effects of the Project on sturgeon, eulachon, and salmon spawning grounds | The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon and salmon to Tsawwassen. Potential Project-related effects on fish and fish habitat are presented in Section 4.4 of the Application. | Addressed | Implementation of mitigation measures outlined in 4.4.4 (Fish and Fish Habitat Mitigation Measures) |
| Effects of lighting on fish | Potential Project-related effects on fish and fish habitat are presented in Section 4.4 of the Application. | Addressed | Implementation of mitigation measures outlined in 4.4.4 (Fish and Fish Habitat Mitigation Measures) |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|---|
| <p>Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon</p> | <p>Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources can be mitigated effectively by scheduling such activities during periods of low tide, when work can be completed under shall water conditions or in the dry, thereby minimizing potential effects. No Project-related residual or cumulative effects on underwater noise conditions are expected. Underwater Noise and Fish and Fish Habitat are addressed in Sections 4.3 and 4.4 of the Application.</p> | | <p>Implementation of mitigation measures outlined in 4.3.4 (Underwater Noise Mitigation Measures) and 4.4.4 (Fish and Fish Habitat Mitigation Measures)</p> |
| <p>Accommodation of construction windows for fish cycle spikes (i.e. 4 year sockeye and 2 year pink)</p> | <p>To the extent that is technically feasible and viable, sediment removal will be undertaken between July 16th and February 28th, the least-risk timing window for the protection of juvenile salmon and eulachon.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.4.4 (Fish and Fish Habitat Mitigation Measures)</p> |
| <p>Requirement for HAAD (Harmful Alteration, Disruption and Destruction) permit</p> | <p>All required permits will be obtained.</p> | <p>Addressed</p> | <p>Obtain required permits</p> |

4.6 MARINE MAMMALS

Marine mammals, specifically harbor seals and sea lions, are known to use marine areas within the Project alignment. Other species of conversation interest, including southern resident killer whales, do not occur in the Fraser River. Underwater noise during construction is the key area of focus for potential Project-related effects on marine mammals. Underwater noise in the Fraser River South Arm from existing sources currently exceeds thresholds for disturbance to marine mammals approximately 20% of the time. The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.

Effects

A negligible effect on the availability of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

Mitigation

Apply standard industry and best management practices to activities such as pile driving that have the potential to generate underwater noise to ensure sound thresholds for the protection of marine mammals are adhered to.
 Marine Mammal Management Plan to be incorporated into the Construction Environmental Management Plan
 Monitor underwater noise.

Cumulative Effects

No significant Project-related residual or cumulative effects on marine mammals are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|--------------------------|---|
| Potential effects to Tsawwassen Right to Harvest | Tsawwassen’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures in Section 4.6 (Marine Mammals), residual effects on the exercise of Aboriginal Interests by Tsawwassen as a result of the Project are not expected. | Addressed in Application | Implementation of mitigation measures in Section 4.6 (Marine Mammals) |

4.7 VEGETATION

The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development.
 Project components and activities will be primarily located within the existing Highway 99 right-of-way, where the vegetation consists mainly of grassy, mowed verges. Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary marsh that occur in the vicinity of the Project. No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.

Effects

A negligible effect on the availability of vegetation resources for traditional use has been determined.
 A negligible effect on quality of vegetation resources for traditional use has been determined.
 A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

Mitigation

Minimize potential effects through Project design.
 Adhere to best management and environmental, terrestrial vegetation and wildlife management practices. Apply best practices such as flagging of at-risk ecosystems to avoid encroachment during construction.
 Offset and enhance habitat. Create comparable habitat within the Project alignment to offset unavoidable potential Project-related effect, limited to a small reduction in area of the cattail marsh that overlaps with Project components. Replant disturbed areas with native species.
 Invasive species management plan will included in the Construction Environmental Management Plan

Cumulative Effects

No significant Project-related residual or cumulative effects on vegetation are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|--------------------------|---|
| Potential effects to Tsawwassen Right to Harvest | Tsawwassen’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures in Section 4.7 (Vegetation), residual effects on the exercise of Aboriginal Interests by Tsawwassen as a result of the Project are not expected. | Addressed in Application | Implementation of mitigation measures in Section 4.7 (Vegetation) |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|-----------|--|
| Invasive plant species and proposed plans to manage presence during construction | Mitigation and management of invasive species are presented in Section 4.7 of the Application. The Ministry will develop and implement an Invasive Species Management Plan as part of the Construction Environmental Management Plan. | Addressed | Implementation of mitigation measures outlined in Section 4.7.4 (Vegetation Mitigation Measures) |
| Use of culturally significant plants in planting plans | Planting plans will be developed during later stages of Project planning and design. Opportunities for inclusion of culturally significant plants in in planting plans will be considered at that time. The Ministry will consult Aboriginal Groups on the development of these plans. | Addressed | The Ministry will develop planting plans with consultation from Aboriginal Groups |

4.8 TERRESTRIAL WILDLIFE

The Highway 99 corridor is a highly developed area and terrestrial wildlife has generally adapted to this current condition. Terrestrial wildlife along Highway 99 consists primarily of raptors, riverine birds, and small mammals. Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge. No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.

Effects

- A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.
- A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.
- A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

Mitigation

- Minimize potential effects through Project design.
- Adhere to terrestrial vegetation and wildlife management best practices such as spatial and temporal avoidance, pre-construction surveys and nest survey protocols, wildlife salvage and translocation, flagging and management of sensitive areas, and timing window restrictions.
- Habitat enhancement and offsetting.

Residual & Cumulative Effects

- There is a low, short-term probability of barn swallow habitat loss during the construction period. The new bridge will provide new nesting opportunities for barn swallows.
- There is a low, long-term probability of barn owl mortality.
- No significant Project-related residual or cumulative effects on terrestrial wildlife are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|--------------------------|---|
| Potential effects to Tsawwassen Right to Harvest | Tsawwassen’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures in Section 4.8 (Terrestrial Wildlife), residual effects on the exercise of Aboriginal Interests by Tsawwassen as a result of the Project are not expected. | Addressed in Application | Implementation of mitigation measures in Section 4.8 (Terrestrial Wildlife) |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------|-------------------------|
| <p>Potential light and noise effects on wildlife</p> | <p>The Ministry understands that Tsawwassen is concerned with the potential effects of light and noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application.</p> | | |
| <p>Potential effects of the bridge structure on species such as waterfowl and migratory birds and bats</p> | <p>The Ministry understands that Tsawwassen is concerned with the potential effects of the new bridge structure on species such as mammals, waterfowl, bats, eagles and migratory birds. Installation of flight deflectors such as hedgerows at appropriate locations along the highlight will mitigate potential Project-related increase in traffic collision risk. Terrestrial Wildlife in addressed in Section 4.8 of the Application.</p> | | |

4.9 AIR QUALITY

Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in.

Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include a 35% reduction in particulate matter emissions, as compared with a 14% reduction without the Project; a 47% reduction in volatile organic compound emissions, as compared with a 40% reduction without the Project; and no exceedances of the current most stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.

The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.

Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.

Effects

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

Mitigation

Minimize effects through Project design.

Implement recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.

Development of an Air Quality and Dust Control Management Plan for inclusion of the Construction Environmental Management Plan.

Measure and monitor vehicle emissions and road dust during Project operation.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|------------------|-------------------------|
| <p>Effects of change in air quality resulting from increase in traffic volume due to the Project</p> | <p>Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in. Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. The new bridge will allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as the Tunnel portals, where they accumulate today. Effects on air quality during Project construction will be minimized through implementation of recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.</p> | <p>Addressed</p> | <p>None</p> |

4.10 ATMOSPHERIC NOISE

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the highway but do not exceed what is acceptable for residential, educational or institutional facilities.

Effects

No, negligible or measureable effect on quality of experience while engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

Mitigation

Minimize effects through Project design.

Adhere to construction best practices and the Ministry's 2014 *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways*.

Develop and implement a Noise Management Plan.

Noise monitoring program.

Site specific schedules and activities.

Residual & Cumulative Effects

With the application of mitigation, no significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|-------------------------------------|---|-----------|--|
| Potential noise effects on wildlife | The Ministry understands that Tsawwassen is concerned with the potential effects of noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application. | Addressed | Implementation of mitigation measures outlined in Section 4.8.4 (Terrestrial Wildlife Mitigation Measures) |

5.2 MARINE USE

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, and sorting and booming, as well as commercial, recreational and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place within the vicinity of the Project.

A clear span crossing of the Fraser River is proposed to avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span to improve navigation in and out of the slough.

Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.

Effects

A negligible effect on access to instream locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Development and implementation of a specific Tsawwassen First Nation marine use protocol through direct consultation with Tsawwassen First Nation.

Develop and implement a Marine Access Management Plan to ensure that important marine use activities can be reconciled with temporary constraints associated with Project construction.

Establish communications protocols to advise in-stream construction activities.

Ensure appropriate lighting and marking for safe navigation.

Establish navigation protection zones during construction to avoid or minimize impact on marine use.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on marine access are expected

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|-------------|---|
| Potential effects of construction during fishing season on fishing activities | <p>Potential interference with fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> <p>The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided.</p> | Addressed | Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4 (Marine Use Mitigation Measures) |
| Impacts of Tunnel decommissioning on Aboriginal fisheries, specifically as it relates to timing | <p>Potential interference with fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> <p>The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided.</p> | Addressed | Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4 (Marine Use Mitigation Measures) |
| Inappropriateness/inadequacy of Marine Users Group for consultation with Tsawwassen | <p>The Ministry is continuing to work with Tsawwassen to better understand how they would like to participate in the development and implementation of mitigation measures in particular, in relation to alternatives to a marine users group.</p> | In progress | Ongoing consultation |

5.3 LAND USE

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta.

The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect regional growth trends or current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.

Once the new bridge becomes operational, recreational experience in its vicinity is expected to change due to improvements in local air quality, shoreline restoration of Deas Island, and re-vegetation of areas currently supporting highway infrastructure; improved connectivity across the Deas Island Regional Park resulting from removal of the Tunnel portals; and shading adjacent to the bridge, overhead noise, and changes in local viewsapes.

The Project will not result in changes to existing land use beyond small amounts of land, outside of the existing right-of-way, that area required for the Project.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Address temporary effects on existing land use during construction and incorporate land use considerations into a Traffic Management Plan.

Incorporate land use considerations into a Marine Access Management Plan.

Reconnect recreational trails.

Residual & Cumulative Effects

There is a high, short-term probability of disturbance to residential, commercial and industrial land uses.

There is a high, short-term probability of disturbance to recreational uses near the new bridge.

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Tsawwassen has not voiced any concerns or issues with Land Use | | | |

5.5 VISUAL QUALITY

The new bridge will add noticeable visual features to the landscape and will change visual conditions adjacent to the Project alignment. Replacement of interchanges also has the potential to change visual conditions of these locations. At distances greater than one kilometer, the bridge deck will merge with the natural landscape and the main visual features will be the bridge towers. Changes in visual quality at interchanges will be minor as visual quality in such areas is currently influenced by existing transportation infrastructure.

Effects

During construction, no to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

During operation, a measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Minimize effects through Project design.

Use of vegetated buffers to minimize visual effects to residential developments within close proximity to the bridge in Delta.

Residual & Cumulative Effects

There is a moderate, long-term probability of disturbance to visual quality

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--------|---------------------------|--------|-------------------------|
|--------|---------------------------|--------|-------------------------|

| | | | |
|---|--|--|--|
| Tsawwassen has not voiced any concerns or issues with Visual Quality. | | | |
|---|--|--|--|

6.1 HERITAGE RESOURCES

The Project is located in an area where substantial historical development has occurred and the majority of the Project alignment is characterized as having low archaeological potential. No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

During construction, no to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

During operation, a measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Develop and implement a Heritage Resources Management Plan, which will include a chance find procedure, to avoid impacts to previously unknown heritage resources that may be encountered during Project construction and operation.

Undertake additional archaeological surveys.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on heritage resources are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------|--|
| Protection of archaeological and heritage resources, including intangible heritage sites | Ministry acknowledges that protection of archaeological sites as well as intangible heritage sites are of utmost importance to Tsawwassen. All Aboriginal Groups have been provided with a comprehensive list of these sites, the Archaeological Overview Assessment, the Archaeological Impact, and Heritage Resources Overview Assessment. Appropriate measures will be taken to ensure the protection of archaeological and heritage resources as outlined in Section 6.1. | Addressed | Implementation of mitigation measures as outlined in Section 6.1.4 |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------|---|
| Participation in archaeological fieldwork and review of archaeological draft reports | Tsawwassen participated in all archaeological field work to date and was provided the opportunity to review draft archaeological reports. | Addressed | Tsawwassen will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports. |

7.0 HUMAN HEALTH

Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health. The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options. The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased active and public transportation, improved traffic safety, improvement connectivity and access, improved emergency response, and economic development opportunities.

Future Project-related consultation with Aboriginal groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.

Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations, and emergency response.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

During construction, a measureable effect on access to instream locations for traditional use has been determined.

7.0 HUMAN HEALTH

During construction, a measurable effect on quality of experience tied to access of instream locations for traditional has been determined.

During operation, a negligible effect on access to instream locations for traditional use has been determined.

During operation, a negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation

Implement proven mitigation measures, effectively used during construction of projects such as the South Fraser Perimeter Road and Port Mann / Highway 1 Improvement, to ensure that temporary increases in ambient noise levels and air emissions during construction do not result in health effects.

Implementation of mitigation measures outlined in Fish and Fish Habitat, Marine Mammals, Vegetation, Terrestrial Wildlife, Air Quality, Atmospheric Noise, Marine Use and Land Use.

Residual & Cumulative Effects

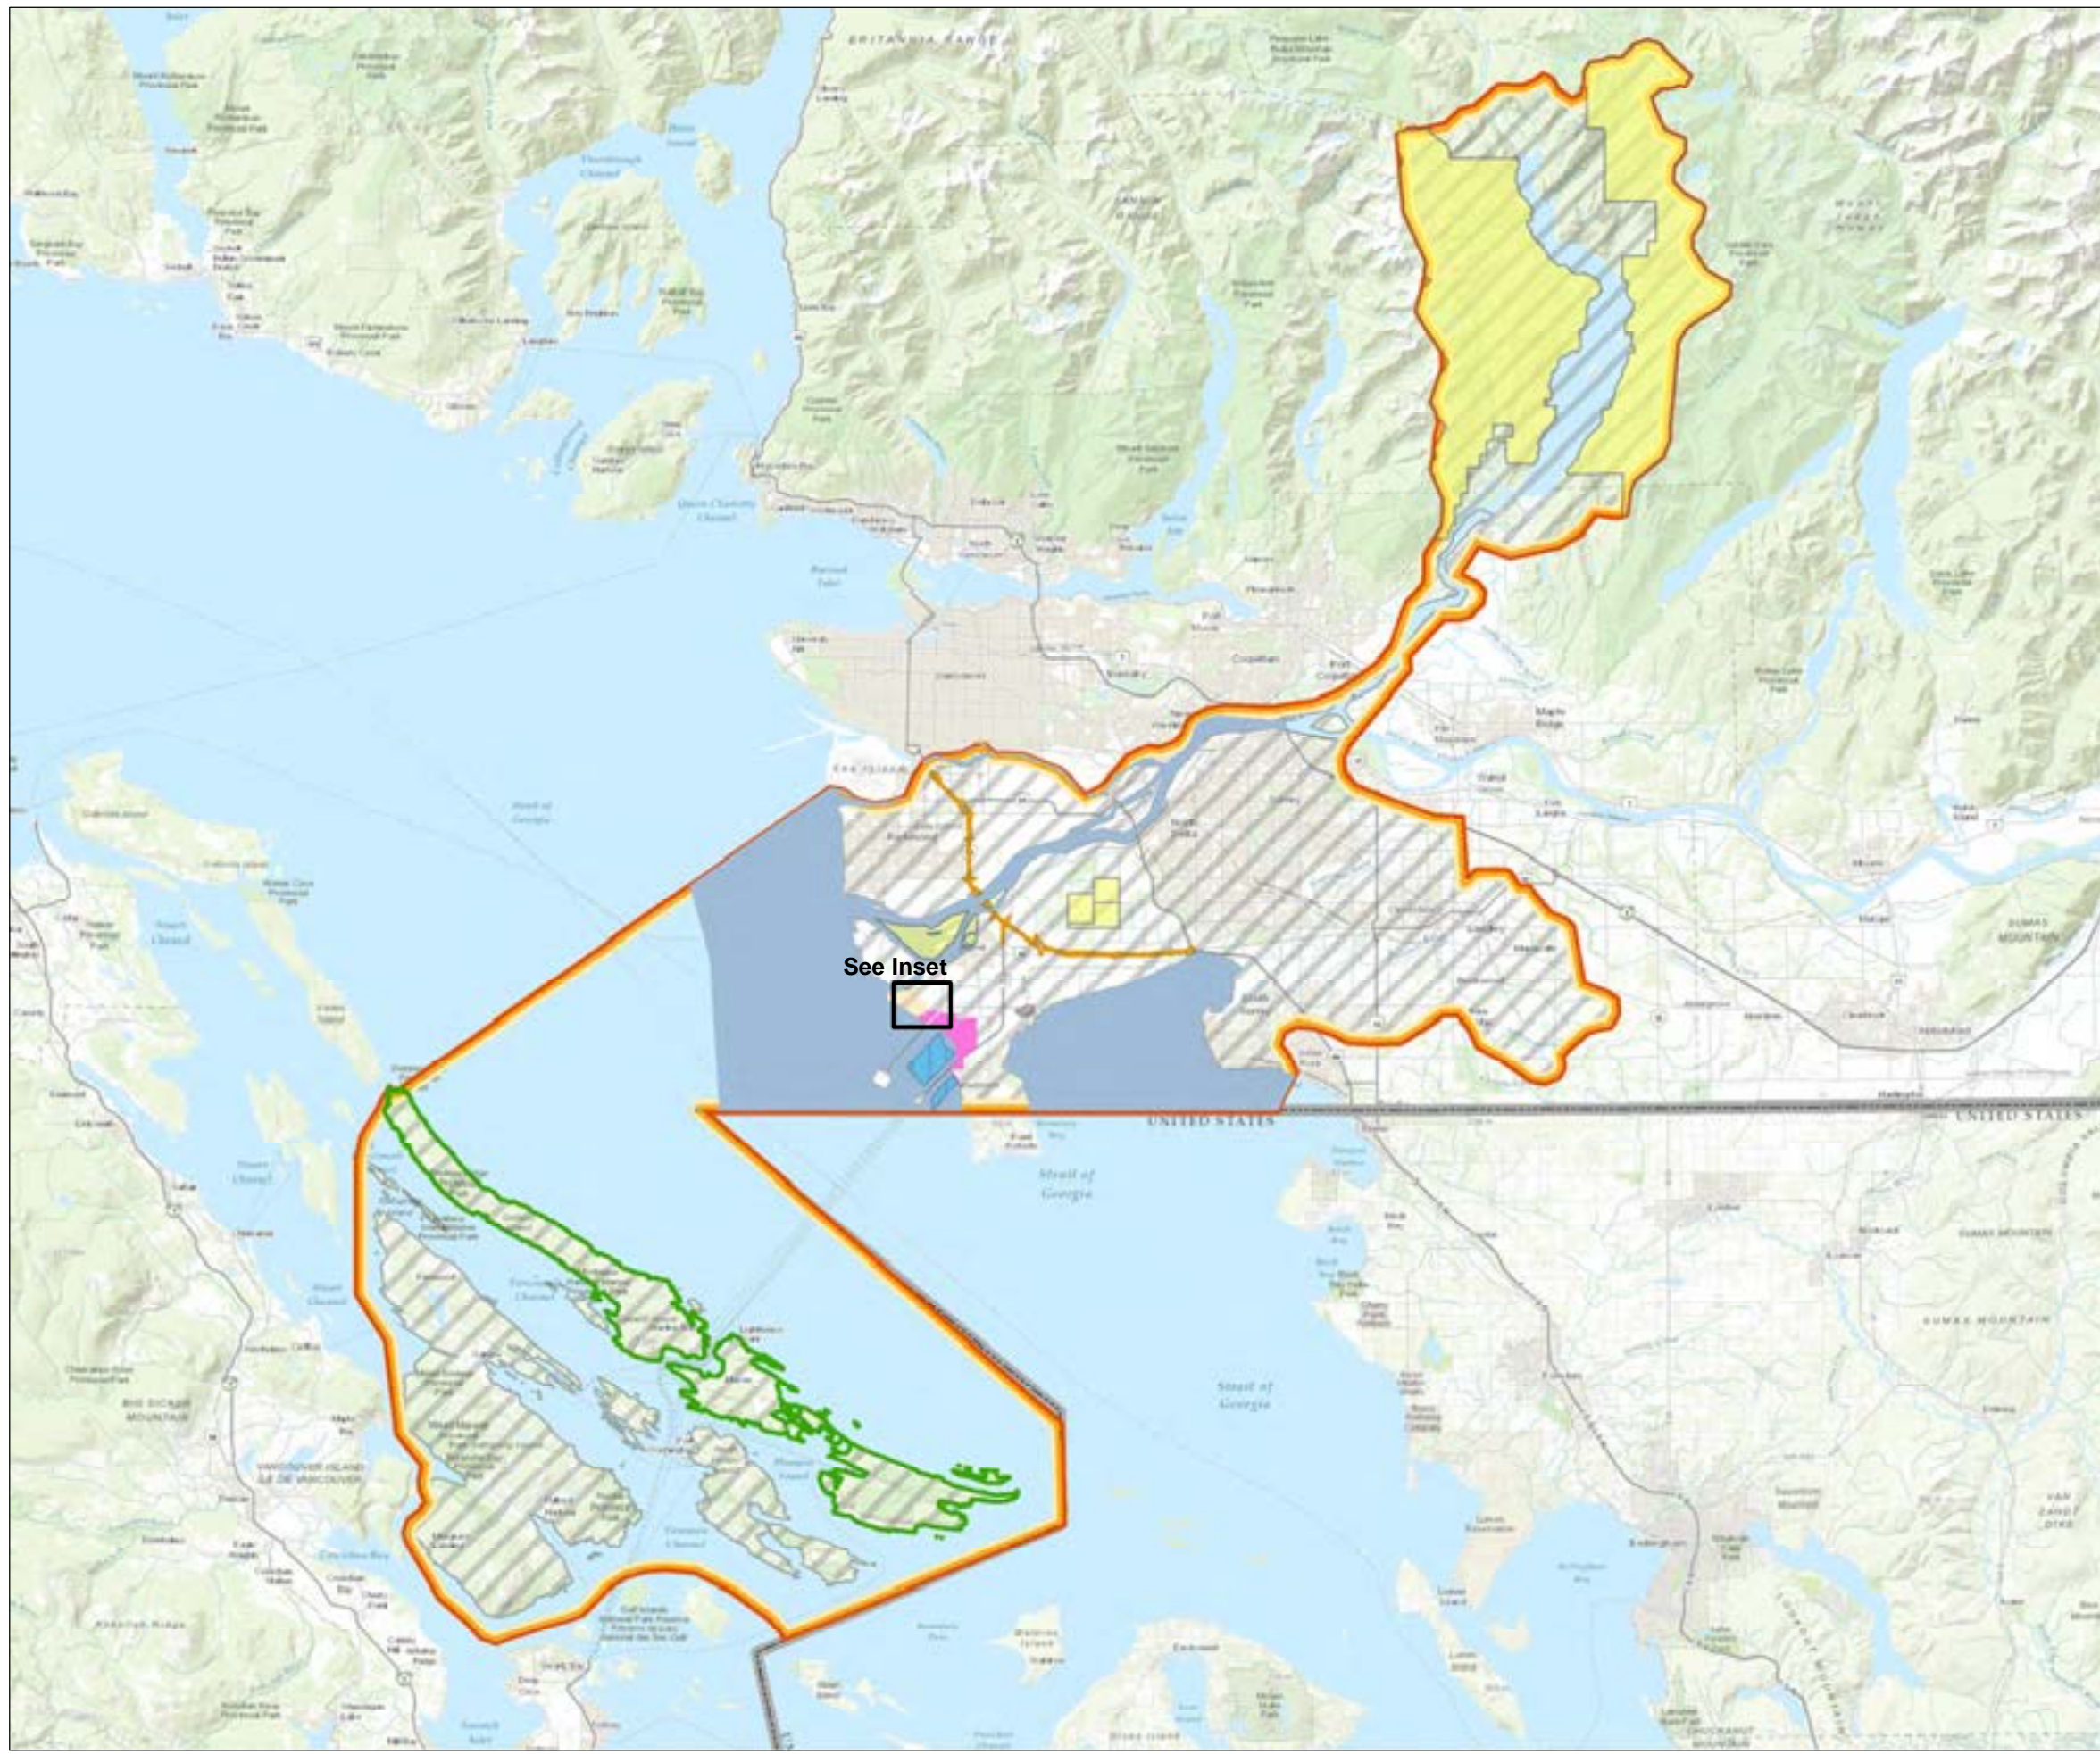

No significant Project-related residual or cumulative effects on human health are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------------------------|--|
| Contamination from harvested species will be passed along to members | Assessments of potential Project-related effects on human health are presented in Section 7.1 of the Application. The Ministry is taking every precaution to ensure that vegetation, fish and fish habitat, and terrestrial wildlife are not contaminated. | Addressed in Application | Implementation of mitigation measures outlined in Sections 4.4.4 (Fish and Fish Habitat Mitigation Measures), 4.7.4 (Vegetation Mitigation Measures), 4.8.4 (Terrestrial Wildlife Mitigation Measures), and 7.1 (Human Health) |

| 8.0 ACCIDENTS AND MALFUNCTIONS | | | |
|---|---|--------------------------|--|
| Adherence to the practices and procedures contained in the Construction Environmental Management Plan will minimize the potential for accidents and malfunctions to occur. In general, replacement of the Tunnel with a new crossing and the proposed highway improvements are expected to lower the risk of accidents and malfunctions during highway operations and maintenance | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations | An Emergency Response and Spill Contingency Plan will outline how construction personnel will prevent, prepare for, respond to, and clean up spills | Addressed in Application | Implementation of mitigation measures outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan) |
| Potential for contamination from fuel and battery acid leaks in soils adjacent to the highway | Any potentially hazardous material identified will be managed in accordance with applicable legislation, including the B.C. Hazardous Waste Regulation, B.C. Reg. 63/88, and the Workers' Compensation Board of B.C. Occupational Health and Safety Regulation, B.C. Reg. 296/97. Spill prevention and management during construction are described in Section 12 of the Application. | Addressed in Application | Adherence to the Construction Environmental Management Plan and applicable legislation |

| OTHER ISSUES | | | |
|---|---|---------------|--------------------------------|
| Consultation with Tsawwassen identified issues outside of the environmental assessment process, Aboriginal Interests, Aboriginal Consultation, Aboriginal Participation and Project-Related Opportunities, and sections of the Application. | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Maintaining access to points connecting to Tsawwassen, specifically access to Highway 17A | As indicated in the Section 16.1 (Draft Reference Concept), the Project will not impact Tsawwassen access. | Addressed | None |
| Length of time tolls are in place | The Province intends to fund the Project, at least in part, through user tolls. This is consistent with the provincial tolling guidelines. Tolling recognizes that those directly benefitting from the new infrastructure in terms of time savings and reliability should help pay for the Project. This ensures that the needed improvements can proceed now, rather than years in the future when improvements will be even more overdue. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application. | Addressed | None |
| Potential increase in vessel traffic on the Fraser River as a result of the decommissioning of the Tunnel | The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. | Addressed | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|------------------|-------------------------|
| <p>Use and disposal of dredged and other material in the river as well as general concerns related to dredging of the Fraser River</p> | <p>Dredging to deepen the river is not a component of this Project and the Ministry is unaware of any plans by others to dredge the river deeper. The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. This is outlined in Sections 1.1.7.2 (Construction), 4.1 (River Hydraulics) and 4.2 (Water Quality and Sediment) of the Application.</p> | <p>Addressed</p> | <p>None</p> |

APPENDIX O

Tsleil-Waututh Nation

1.0 Introduction

This appendix provides a summary of the information presented in Part C Aboriginal Consultation (Part C) of the Application for an Environmental Assessment Certificate (the Application) regarding the assessment of effects on Aboriginal Interests. Aboriginal Interests are defined as asserted or determined Aboriginal rights, including title, or treaty rights. This appendix presents the information specific to Tsleil-Waututh Nation (Tsleil-Waututh).

The organization of the information presented generally follows Part C and includes the following sections:

- Consultation;
- Community Profile;
- Existing Conditions;
- Potential Effects;
- Mitigation;
- Residual Effects; and
- Summary and Conclusion.

For more detailed information on the effects assessment on Aboriginal Interests related to Tsleil-Waututh, refer to the following sections of Part C:

- Consultation with Tsleil-Waututh (**Section 10.1.2.10**);
- Tsleil-Waututh community profile (**Section 10.1.1.11**);
- Description of existing Tsleil-Waututh Aboriginal Interests (**Section 10.1.3.2**);
- Assessment of potential effects of the Project on the exercise of Tsleil-Waututh's Aboriginal Interests (**Section 10.1.3.3**);
- Mitigation relating to potential effects on Aboriginal Interests (**Section 10.1.3.4**); and
- Residual effects on Tsleil-Waututh's Aboriginal Interests following application mitigation (**Section 10.1.3.5**).

A summary of the Aboriginal Interests Assessment for Tsleil-Waututh is also provided in **Section 10.1.3.8**.

The summary presented in this appendix also incorporated information found in the Tsleil-Waututh Overview Table (**Appendix O2**), which provides detailed information regarding:

- Tsleil-Waututh's issues and concerns identified to date;
- Identification of potential effects on VCs and ICs that relate to the assessment of effects on Tsleil-Waututh's Aboriginal Interests;
- The Ministry's response to specific issues and concerns raised by Tsleil-Waututh;
- The status of these issues and concerns; and
- Next steps required to address outstanding issues and concerns.

2.0 Consultation

This section provides information regarding the consultation activities that the EAO and Ministry carried out prior to submission of the Application.

2.1 EAO-led Consultation Activities

2.1.1 Capacity Funding

When a provincial agency is a proponent of a project going through a provincial EA under the British Columbia *Environmental Assessment Act* (BCEAA), that agency provides funding to Aboriginal Groups to support their involvement in pre-Application and Application review phases in place of EAO providing such funding. The Ministry's provision of capacity funding is discussed in the following section, Proponent-led Consultation Activities.

2.1.2 Participation in Working Group

EAO invited Tsleil-Waututh and all other Aboriginal groups identified in Schedule B of the Section 11 Order to participate as members of a Working Group.

During the Pre-Application stage, Tsleil-Waututh attended two EAO-led Working Group meetings where the Ministry presented information on the Project and the environmental assessment process and received and responded to comments on those presentations.

The first Working Group meeting, held January 2016, focused on the environmental assessment process, Project overview and update, Key Areas of Study, draft Application Information Requirements overview, and preliminary conclusions from study results.

The second working group meeting, held March 2016, focused on the environmental assessment process, list of materials available on the Project website, review of comments received on, and resulting changes to, the draft Application Information Requirements, and a description and rationale of the assessment areas. Working Group comments raised by Tsleil-Waututh in relation to the draft Application Information Requirements resulted in Aboriginal Groups being invited to participate in river-otter related fieldwork in April 2016. The objectives of this work were to document river otter presence or potential presence with the Regional Assessment Area, document and describe use of riparian and high use areas and identify potential Project-related effects.

Tsleil-Waututh also participated in the completeness review of the Application that considered whether the Application included information requirements set out in the Application Information Requirements.

It is anticipated that Tsleil-Waututh will continue as an active member of the Working Group through the environmental assessment process.

2.2 Proponent-led Consultation Activities

The Ministry began consultation with Tsleil-Waututh in early 2014 in order to identify the nature and scope of Tsleil-Waututh's Aboriginal Interests and how they might be impacted by the Project. Following is a summary of consultation activities led by the Ministry with Tsleil-Waututh. A more detailed discussion is provided under the Tsleil-Waututh section in **Section 10.1.2.10 Overview of Consultation with each Schedule B Aboriginal Group**. The following sections represent the main activities undertaken in support of Proponent-led consultation and include the following:

- Provision of capacity funding;
- Traditional use, traditional knowledge and other studies;
- Examples of Consultation Activities; and
- Concerns Identified to Date.

2.2.1 Capacity Funding

The Ministry entered into a Participation Funding Agreement, including the Initial Consultation and Pre-Application phases for consultation, with Tsleil-Waututh. The Ministry has been working with Tsleil-Waututh regarding their needs for capacity funding to facilitate their participation in the Application Review Phase. Consultation activities that are anticipated to be undertaken during the Application Review phase that will be supported by capacity funding include participation in technical reviews and analyses, involvement in ongoing consultation activities, and presentation of key information regarding their respective Aboriginal Interests.

2.2.2 Traditional Use, Traditional Knowledge & Other Studies

The Ministry provided additional funding to Tsleil-Waututh for the preparation and submission of the traditional use study: *Tsleil-Waututh Knowledge Study for the George Massey Tunnel Project*. The purpose of such studies is to identify Aboriginal input and traditional knowledge for inclusion and consideration in the EA. In addition, studies were funded to enhance the Ministry's understanding of Aboriginal Interests and Aboriginal Group's past, present and desired future use as it pertains to the exercise of Aboriginal Interests within the Project area and the potential adverse effects on identified Aboriginal Interests.

2.2.3 Examples of Consultation Activities

A number of consultation activities were undertaken with Tsleil-Waututh during both the Initial Consultation Phase and the Pre-Application Consultation Phase as follows:

Initial Consultation Phase Activities - The Ministry recognized the importance and value of early engagement with Schedule B Aboriginal Groups and undertook an Initial Consultation Phase prior to the Pre-Application Phase. The Initial Consultation Phase concluded in December 16, 2015 with submission of the Project Description and Key Areas of Study document. The focus of the Initial Consultation Phase was collection of baseline information and sharing of draft EA-related documents (i.e. Project Description and Key Areas of Study, Application Information Requirements (AIR)). The main consultation activities the Ministry undertook with Tsleil-Waututh included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Tsleil-Waututh;
- Funding for Tsleil-Waututh 's participation in Project consultation activities and EA process;
- Tsleil-Waututh participation in field studies;
- Site visit;
- Review of draft EA documents such as the Project Description and Key Areas of Study, Heritage Resources Overview Assessment/Archaeological Overview Assessment, Heritage Resources Assessment, AIR and Aboriginal Consultation Plan;
- Meetings with Tsleil-Waututh leadership, staff, consultants, elders and membership; and
- Response and follow up with Tsleil-Waututh regarding the identification and resolution of issues.

Pre-Application Consultation Phase Activities - The Pre-Application Consultation Phase began with the filing of the Project Description and Key Areas of Study on December 16, 2015 and concluded with the submission of the Application. This phase included the issuance of Section 11 Order, AIR development and collection of baseline information (may include submission of permit applications). The main consultation activities the Ministry undertook with Tsleil-Waututh included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Tsleil-Waututh;
- Funding for Tsleil-Waututh’s participation in Project consultation activities and EA process;
- Meetings with Tsleil-Waututh leadership, staff, consultants, elders and membership;
- Tsleil-Waututh participation in fieldwork;
- Tsleil-Waututh participation in the EA Working Group;
- Review of draft EA documents such as the Application Information Requirements and Aboriginal Consultation Reports;
- Review of components of draft Part C of the Application; and
- Response and follow up with Tsleil-Waututh regarding the identification and resolution of issues.

2.2.4 Concerns Identified to Date

As outlined above, Tsleil-Waututh’s concerns, identified through consultation undertaken to-date, are presented in **Appendix O2 Tsleil-Waututh Nation Overview Table**. The Ministry’s response to Tsleil-Waututh’s key concerns regarding potential impacts on Tsleil-Waututh’s Aboriginal Interests are outlined below:

Table 1 Concerns Identified to Date

| Concerns Identified to Date | Response |
|---|--|
| <p>Potential effects to Tsleil-Waututh Right to Harvest</p> <ul style="list-style-type: none"> • Fish • Marine Mammals • Vegetation • Terrestrial Wildlife | <p>Tsleil-Waututh’s rights to harvest within the Project area are addressed in Part C of the Application.</p> <p>With the implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife), residual effects on the exercise of Aboriginal Interests by Tsleil-Waututh as a result of the Project are not expected.</p> |
| <p>Aboriginal participation and Project-related opportunities</p> <ul style="list-style-type: none"> • Potential employment, training, contracting and economic development opportunities • Cultural recognition and naming • Revenue sharing opportunities from tolling | <p>The Ministry is committed to working with Tsleil-Waututh to identify potential employment, training, contracting and economic development opportunities and to identify ways to support community preparedness.</p> <p>The Ministry is exploring opportunities for cultural recognition and naming and will work with Tsleil-Waututh on these opportunities.</p> <p>The provincial tolling strategy stipulates that revenue from tolling may only be used to defray the costs of designing, constructing, operating and maintaining highways.</p> |

| Concerns Identified to Date | Response |
|--|--|
| <p>Effects to fish and fish habitat</p> <ul style="list-style-type: none"> • Importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon • Evaluation on impacts to ecological services for all ecosystems within the vicinity of the Project • Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon, salmon to Tsleil-Waututh and is committed to avoiding or mitigating any potential effects.</p> <p>Pacific salmon species selected for Project-related baseline studies include Chinook salmon, Chum salmon, Coho salmon, Pink salmon, and Sockeye salmon. Using existing scientific and literature, baseline conditions will be described for all life history stages of each salmon species, with emphasis on those life history stages that use aquatic habitats within the Project Area. Fish sampling focused on potential rearing values within drainage ditches in Richmond and Delta, for which limited existing inventory information exists, has been incorporated into the baseline studies.</p> <p>The Ministry designed a clear span bridge over the Fraser River South Arm and Deas Slough to avoid or minimize Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Tsleil-Waututh’s Fisheries Department continues to be very helpful in the review of Green Slough concepts.</p> <p>As outlined in Section 4.3 (Underwater Noise), sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources will be effectively mitigated by scheduling activities during period of low tide, when work can be completed under shallow water conditions or in the dry.</p> |

| Concerns Identified to Date | Response |
|--|---|
| <p>Environmental Assessment (EA):</p> <ul style="list-style-type: none"> • Adequacy of methodology to address social and cultural effects • Effectiveness of the EAO-led process • Inclusion of Economic Effects Assessment as part of EA • Consideration of cultural assessment methodology | <p>The Ministry acknowledges the importance of Tsleil-Waututh’s involvement in the environmental assessment process.</p> <p>Tsleil-Waututh’s concerns related to Environmental Assessment including the adequacy of methodology to address social and cultural effects, effectiveness of the EAO-led process, inclusion of economics effects assessment, and consideration of cultural assessment methodology are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> |
| <p>Social effects of the Project on Tsleil-Waututh’s ability to transfer knowledge, language and participate in socio-cultural practices</p> | <p>Social effects of the Project on Tsleil-Waututh’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of Part C of the Application.</p> |

| Concerns Identified to Date | Response |
|---|--|
| <p>Cumulative effects:</p> <ul style="list-style-type: none"> • Consideration of cumulative effects on Aboriginal rights • Absence of comprehensive study on cumulative effects on the Fraser River | <p>The Application includes historical context relating to changes in use over time by Tsleil-Waututh and other Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by Tsleil-Waututh or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests.</p> <p>While the Ministry acknowledges that Tsleil-Waututh is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project.</p> |
| <p>Disturbance to benthic and aquatic invertebrates and their habitat</p> | <p>Aquatic habitats, which include habitat for fish and other aquatic species (including benthic and aquatic invertebrates), will be a primary area of focus for the environmental assessment of the Project.</p> <p>Potential disturbance to benthic and aquatic invertebrates is not, on its own, proposed as a key area of study given the nature of the project and the aquatic habitats it overlaps with. Aquatic habitats overlapping with the Project occur within a section of the Fraser River that is dynamic, influenced by large flow variations and downstream transport of sand and organic matter. Therefore, aquatic and benthic invertebrate communities in the Project Area are expected to be resilient to physical disturbance. Given the temporary and short-term changes in flow and water quality expected from Project activities, it is anticipated that the benthic and aquatic invertebrates will recover rapidly from disturbance.</p> |
| <p>Effects on southern resident killer whales within 10 km of Project area</p> | <p>The Project is not anticipated to affect southern resident killer whales (SRKW). Based on the results of underwater noise modelling completed to date, underwater noise generated by Project-related activities is not predicted to extend outside of the Fraser River, and therefore will not affect SRKW. In addition, studies completed to date also indicate that SRKW prey (i.e., chinook salmon) in the Fraser River is not likely to be affected by the Project at a level that could affect the survival or recovery of SRKW.</p> |

| Concerns Identified to Date | Response |
|--|---|
| Interest in considering methods in addition to barriers, for suicide prevention. | <p>The Ministry is in the process of developing a policy in which new bridges in the Lower Mainland will require the installation of safety barriers. The Ministry is committed to including safety barriers as part of the design of the new bridge and will continue to discuss additional measures with Tsleil-Waututh.</p> <p>Assessment of potential Project-related effects on human health, including community and social factors, are presented in Section 7.1 of the Application.</p> |
| Consideration of smart technologies in Project design | <p>The Ministry is developing an Intelligent Transportation System Strategy for the Highway 99 corridor as part of the Project scope. Proposed infrastructure includes a fibre optic network connecting the highway to the Regional Transportation Management Centre, cameras providing coverage of the highway, vehicle detection sensors, changeable message signs and additional infrastructure to allow for expansion of the system as new technologies come into use.</p> |

3.0 Community Profile: Tsleil-Waututh Nation

Tsleil-Waututh is governed by a chief and council with two-year terms under an *Indian Act* electoral system. The current term for the six-member council expires in March 2017). The main Tsleil-Waututh community is located in North Vancouver, on the shore of Burrard Inlet, approximately 2 km east of the north end of the Second Narrows Bridge, on Burrard Inlet 3. Two other reserves, Inlailawatash 4 and Inlailawatash 4A, are located on Indian Arm. Of 578 registered members, 287 reside on Tsleil-Waututh reserves. The Project area does not overlap any current or former reserve lands of the Tsleil-Waututh Nation.

Tsleil-Waututh's Consultation Area extends from the vicinity of Mount Garibaldi in the north to the 49th parallel (and beyond) in the south, Gibsons in the west, and Coquitlam Lake in the east. Tsleil-Waututh Nation report that this Consultation Area encompasses all the waters and lands used by Tsleil-Waututh during extensive seasonal rounds of travel and resource harvest, and includes both areas exclusively occupied and governed by Tsleil-Waututh and areas to which Tsleil-Waututh is granted access according to Coast Salish protocols. The Project area lies fully within this Consultation Area.

Tsleil-Waututh established an Economic Development Department in 1992. The Nation owns and operates several businesses, including Takaya Developments Ltd. (real estate development), Takaya Tours (cultural tourism), TWN Wind Power Inc. (small wind turbine distribution), Inlailawatash Forestry Limited Partnership (natural and cultural resources consulting service), Salish Seas Limited (a partnership between Tsleil-Waututh Nation, Sliammon First Nation, and Tsleil-Waututh Indian Band), TWN and Aquilini Group, and SPAL General Constructors, a project management company co-owned with Tsawwassen First Nation. Other important related Tsleil-Waututh organizations and agreements include the First Nations Legacy Society (also involving Katzie First Nation, Kwantlen First Nation, Kwikwetlem First Nation, Tsleil-Waututh Indian Band, and Tsawwassen First Nation) and the MST Land Protocol.

3.1 Tsleil-Waututh Nation Aboriginal Interests: Existing Conditions

This section provides a high level of summary of past, present, and desired future use of the proposed Project area and surroundings for traditional purposes that are or may be connected with the exercise of Tsleil-Waututh's Aboriginal Interests. A more detailed discussion, including sources used, is provided under Tsleil-Waututh in **Section 10.1.3.2 Existing Conditions**.

3.1.1 General

- Tsleil-Waututh has Aboriginal Interests that are known to overlap or lie in the vicinity of the Project corridor, which includes a portion of the South Arm of the Fraser River.
- Tsleil-Waututh has identified past and ongoing effects that have altered and reduced use over time, constraining the current exercise of their Aboriginal Interests. Tsleil-Waututh has identified a desire to regain or increase, based on past patterns and levels of use, the exercise of Aboriginal Interests in relation to locations or resources that may be affected by Project components or activities.
- Tsleil-Waututh have previously stated that all the lands and waters draining into Burrard Inlet and Indian Arm constitute their core territory (a subset of their Consultation Area), and that their use of the South Arm of the Fraser River was dependent on kinship ties with other *Hə́n̓qə́m̓iḥə́m̓*-speakers (i.e., Tsawwassen, Tsleil-Waututh).
- While Tsleil-Waututh continue to access the Fraser River for sockeye, it is not believed the Tsleil-Waututh assert title in or near the Project area.

3.1.2 Fishing

- Marine resources were and remain central to Tsleil-Waututh for subsistence and cultural life. Salmon was a food staple, supported by the harvest of the full range of shellfish, including bivalves and crustaceans, sturgeon, a variety of groundfish (e.g., halibut, cod, sole, flounder, lingcod, rockfish, among others), eulachon, herring, and smelt, as well as aquatic plants, such as seaweeds. Seals, porpoises, and sea lions were also harvested. Tsleil-Waututh have said that access to different species of salmon was important because of their different qualities and requirements for preservation.
- Resources were used immediately, or processed and stored for use in the winter while resident in large villages in and around Burrard Inlet, where the present-day community still lives.
- Tsleil-Waututh report they hold a close cultural and spiritual connection to salmon; however, sockeye salmon do not run in the tributaries of Burrard Inlet. Tsleil-Waututh has previously reported that their ancestors historically accessed sockeye on the South Arm of the Fraser River through kinship ties, moving to the area in July and August, where they would reside at Tsleil-Waututh seasonal villages with other *Hə́n̓qə́m̓iḥə́m̓*-speaking groups (i.e., Tsawwassen). Historically, they would paddle back to Burrard Inlet village sites with thousands of preserved sockeye from the Fraser River to last throughout the year.
- Fraser River sockeye remain a primary traditional food source for Tsleil-Waututh families, and salmon, herring, and crab are among the species that still contribute to the contemporary economy of Coast Salish peoples.

- Sturgeon and eulachon were also harvested while resident on the river, which the Tsleil-Waututh also used as a travel corridor. Tsleil-Waututh report that, historically, billions of eulachon returned to the Fraser River to spawn, providing them with an important early season fishery. Typically they dried eulachon.
- Currently, they occasionally receive Fraser River eulachon through relatives and cultural protocols. Sturgeon, due to its decline, is no longer a component of Tsleil-Waututh diet. It is their goal to participate in the recovery of these species and their habitats for future generations.
- Tsleil-Waututh may fish for FSC purposes under communal licences issued by DFO. There are a number of PFMA subareas to which these licences apply, including subareas 29-13 and 29-14, which overlap the Project corridor.
- Tsleil-Waututh reports that they have an extensive Fraser River sockeye fishery each year, and for the most part, when there are no conservation concerns, Tsleil-Waututh says they fulfil their communal allocation. The largest fishing effort occurs in August. Tsleil-Waututh has also participated in, and continues to reserve the right, to a limited participation fishery for ceremonial purposes outside of the regular Tsleil-Waututh sockeye fishing season.
- Tsleil-Waututh have advised that, in every year since 2008, they have requested a communal licence for Chinook. With the exception of limited participation access in 2009, 2010, and 2014, Tsleil-Waututh Nation has not been granted a DFO communal licence for Chinook. In 2014, Tsleil-Waututh requested communal licences for Fraser River chum. As of 2016, Fraser River chum and pink salmon allocations have been added to Tsleil-Waututh Nation's Comprehensive Fisheries Agreement (CFA).
- In addition to communal licences issued by DFO, Tsleil-Waututh report that they may access food fish through other means, such as through cultural protocols and kinship ties with neighbouring communities, when DFO communal licences are unavailable.
- Tsleil-Waututh advise that they seek to access, protect, and restore traditional foods for future generations, and current and future desired use. For example, Tsleil-Waututh report that they have submitted multiple requests to DFO to access Fraser River eulachon – a species traditionally accessed by Tsleil-Waututh in the Fraser River – but has been denied an allocation.
- Tsleil-Waututh also report having access to PFMA 29 for communal crab licences, and have been working with DFO through an access request process to recognize PFMA 29 for prawn and crab communal fisheries in the Tsleil-Waututh Nation's CFA.
- Fishing is conducted under communal licences on behalf of the community; distributions of fresh fish are made within the community in season and by preserved methods during the winter months.

- In addition to communal FSC access, Tsleil-Waututh Nation’s 2013 CFA with DFO also provides the nation with communal commercial fisheries access through an allocation transfer program.
- Tsleil-Waututh participates in commercial fisheries through Salish Seas Limited Partnership, a business owned jointly with the Tsleil-Waututh Indian Band and Sliammon First Nation.

3.1.3 Hunting/Trapping

- Species hunted historically and continuously by Tsleil-Waututh include ungulates, such as deer and elk, bear, ducks, and other waterfowl.
- Tsleil-Waututh has previously reported that waterfowl were hunted while resident on the South Arm of the Fraser River in July and August. Current waterfowl harvesting by Tsleil-Waututh members in or near the Project area was not identified in sources reviewed.

3.1.4 Gathering

- On southern Lulu Island, around No. 5 Road, Tsleil-Waututh has stated that it harvested berries, and specifically cranberries, while resident on the Fraser River. Tsleil-Waututh has also advised that, in 1870, “Sleholdoo, chief of Slilooet (i.e., Sla-holt, chief of Tsleil-Waututh) was a signatory on a petition to colonial authorities opposing the sale of cranberry patches on the Lower Fraser River.” In addition to demonstrating that Tsleil-Waututh utilized these areas for harvesting cranberries, Tsleil-Waututh consider this to be recognition by other signatory First Nations of Tsleil-Waututh’s “rights of utilization” at this location (TWN 2016). Current gathering activities by Tsleil-Waututh members in or near the Project area were not identified in sources reviewed.

3.1.5 Archaeology and Cultural Heritage Interests

- Tsleil-Waututh have reported that all areas used for traditional purposes, such as fishing, hunting, and gathering, are regarded as sacred. They have explained that the landscape utilized for these purposes was shaped, in the very distant past, by the Transformers—or *Xáls*, *Xexá:ls*, or *Khaals*—who began their journey at the Fraser River delta travelling upstream and creating the world.

3.1.6 Other Related Interests

- Tsleil-Waututh have also explained that waterways within their asserted territory were the principal means of accessing places such as *ł'əqtinəs* (on the north shore of the Fraser River opposite Deas Island); *kwy-yowka* (on the south shore of Lulu Island), and *ʔələqsən* (on the northern end of Westham Island) within the seasonal round of land and resource use.

- Tsleil-Waututh report two historic canoe routes connecting Roberts Bank to Boundary Bay, Canoe Passage, the South Arm of the Fraser River, and Sturgeon Bank, and two fishing villages, one opposite Deas Island in the Fraser River (associated with *λ'əqtinəs*) and the other at Cannery Point, on the southeastern corner of Point Roberts peninsula.
- Tsleil-Waututh has advised that, in 1867, “Slehorte of Slelowet Burrard Inlet Villages” (i.e., Sla-holt, chief of Tsleil-Waututh)...was a signatory of a petition opposing restriction on First Nations travel on the Fraser River.” In addition to demonstrating that Tsleil-Waututh travelled the Fraser River, Tsleil-Waututh consider this to be recognition by other signatory First Nations of Tsleil-Waututh’s “right of unrestricted travel” within this waterway (TWN 2016).

4.0 Potential Effects

This section provides a summary of the methodology used to identify potential adverse effects of the proposed Project on the exercise of Aboriginal Interests by Aboriginal Groups during Project construction and operation, followed by a summary of potential effects on Tsleil-Waututh’s Aboriginal Interests, specifically. For a more detailed description, refer to **Section 10.1.3.3. Potential Effects**.

4.1 Methodology for Identification of Potential Effects

The first step in the effects assessment on Aboriginal interests was the identification of potential adverse effects on traditional use activities and related interests as a result of Project construction or operation. To evaluate these potential adverse effects, the findings of the following Valued Component (VC) chapters in Part B of the Application were considered, including identified mitigation measures, residual effects, cumulative effects and follow up strategies:

- **Section 4.4 Fish and Fish Habitat**
- **Section 4.6 Marine Mammals**
- **Section 4.7 Vegetation**
- **Section 4.8 Terrestrial Wildlife**
- **Section 5.2 Marine Use**
- **Section 5.3 Land Use**
- **Section 5.5 Visual Quality**
- **Section 6.1 Heritage Resources**
- **Section 7.1 Human Health**

The findings of the following Intermediate Component (IC) chapters were also considered in the assessment:

- **Section 4.1 River Hydraulics and River Morphology**
- **Section 4.2 Sediment and Water Quality**
- **Section 4.9 Air Quality**
- **Section 4.10 Atmospheric Noise**

The assessment of potential adverse effects of the Project on the exercise of Aboriginal Interests, including measures to address those effects, are presented in **Section 10.1.3.3** through **Section 10.1.3.5**, and largely applies the same methods used in Part B of the Application for the IC and VC assessments, as outlined in **Section 3.0 Assessment Methodology**.

In addition to information from the VC and IC assessments that support the assessment of potential effects on Aboriginal Interests, information from a Health Impact Assessment (HIA) undertaken to support Project planning, including mitigation recommendations, has been integrated into the assessment of potential effects on Aboriginal Interests. The HIA for the Project can be found at <https://engage.gov.bc.ca/masseytunnel>. A summary of the key findings is provided in **Section 7.2 Health Impact Assessment**.

4.2 Selection of Indicators

Four parameters were chosen as indicators to understand and evaluate potential Project-related effects on the exercise of Aboriginal Interests. The rationale for their selection is presented in the following table.

Table 2 Indicators for the Aboriginal Interests Assessment

| Indicator | Rationale for Selection |
|---|---|
| Access to preferred locations for the exercise of Aboriginal Interests | Project components or activities could result in changes in access to or patterns of travel between traditional use locations on land or water |
| Availability of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in distribution or movement, relative abundance, or habitat area or composition of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in the real or perceived quality of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests | Project components or activities could result in: (1) direct sensory disturbance to traditional users (e.g., from noise, vibration); and/or (2) indirect changes to cultural practices, customs or traditions – i.e., cultural heritage or the expression and transfer of cultural values or ways of knowing (e.g., language, laws/governance, stories, spiritual beliefs) – tied to the cultural landscape or to the traditional use of specific traditional use locations or resources within that landscape. |

Potential adverse effects on the indicators noted above were analyzed in terms of the type and level of effect that Project components and activities may be expected to have on the exercise of Aboriginal Interests.

For the purposes of this assessment, no effect was understood to mean that no interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests would be expected. Where it was determined that an interaction, and potential effect, could occur, the following definitions were used to guide the characterization of the effect as negligible or measurable:

- Negligible – An interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests may occur, but modifications to the use of preferred options would not be expected.

- Measurable – Modifications to the exercise of Aboriginal Interests at preferred locations or in relation to preferred resources may be needed, and may be considered to be:
 - Minor (minimal or temporary modifications may be required to use preferred options),
 - Moderate (more frequent or longer term modifications may be required to use preferred options), or
 - Serious (permanent or indefinite modifications may be required potentially resulting in the loss of preferred options).

4.3 Identified Potential Effects

As noted above, the first step in evaluating potential adverse effects on Aboriginal Interests was a consideration of the findings for relevant Part B VCs, including identified mitigation measures, residual effects, cumulative effects and follow up strategies. The residual effects with the potential to result in an adverse effect on Aboriginal Interests are then carried forward in the assessment. Using the four indicators noted in the previous section, the potential Project-related effects and level of effect predicted in relation to Tsleil-Waututh’s exercise of Aboriginal Interests remaining after Part B mitigation are as follows:

Table 3 Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|---|--------------|------------|------------|------------|----------------------------|
| | Negligible | Measurable | Negligible | Measurable | |
| River locations for traditional use as a result of changes to physical characteristics of these locations | ✓ | | ✓ | | |
| Instream locations for traditional use | ✓ | | ✓ | | |
| Upland locations for traditional use | ✓ | | ✓ | | |

| Cultural landscape | | ✓ | | ✓ | <p>Construction - Potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance</p> <p>Operation - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses.</p> |

4.4 Potential Project-Related Effects on Tseil Waututh’s Aboriginal Interests

Using the methodology presented in **Section 10.1.3.3 Potential Effects**, Table 7 provides the potential incremental Project-related effects, following mitigation of Project-related effects on Part B VCs and ICs as described in Part B, related to Tseil Waututh’s Aboriginal Interests of Fishing, Hunting/Trapping, Gathering, Archaeology and Cultural Heritage and Other Related Interests as summarized in Existing Conditions were identified for Project Construction and Operation. A discussion of potential Project-related effects on fishing, hunting/trapping, gathering and archaeology and cultural heritage follows the table.

Table 7 Summary of Potential Project-Related Effects

| Indicator | Potential Project-Related Effect | Potentially-Affected Aboriginal Interests |
|--|---|--|
| Project Construction | | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |

4.5 Fishing

Tsleil-Waututh report that marine resources were and remain central for subsistence and cultural life. Salmon was a food staple, and additional species harvested include the full range of shellfish, sturgeon, groundfish, eulachon, herring, and smelt, as well as aquatic plants. Seals, porpoises, and sea lions were also harvested. Tsleil-Waututh has previously reported that their ancestors historically accessed sockeye on the South Arm of the Fraser River through kinship ties, moving to the area in July and August

The proposed Project has the potential to affect fishing practices through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred fishing locations by Tsleil-Waututh, as a result of changes in river hydraulics or morphology, are expected to be negligible before mitigation. Potential changes in access to instream locations for fishing by Tsleil-Waututh during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to fishing locations by Tsleil-Waututh from instream construction activities are expected to be negligible. While it is acknowledged that Tsleil-Waututh has reported a desire for higher levels of use in this portion of the river based on historic use, the

episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Mitigation measures identified in the fish and fish habitat assessment to address Project-related effects on fish are expected to be effective at addressing potential effects on the availability of fishing resources preferred by Tsleil-Waututh. Further, as residual effects on fish identified in the fish and fish habitat assessment are not anticipated to affect population integrity, potential residual effects as a result of Project construction activities, would not be expected to measurably affect the availability of preferred fish resources.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of fishing resources preferred by Tsleil-Waututh; therefore, Potential Project-related effects on Tsleil-Waututh fishing would be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when fishing are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** are expected to largely address a potential Project-related effect to the quality of experience while fishing. At preferred fishing locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Tsleil-Waututh.

Section 5.5 Visual Quality predicts that residual effects to visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Tsleil-Waututh is fishing. As this landscape has been previously modified, the potential Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Tsleil-Waututh's Aboriginal Interests related to fishing are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.6 Hunting/Trapping

Tsleil-Waututh report hunting ungulates, such as deer and elk, bear, ducks, and other waterfowl historically and continuously. Waterfowl were hunted while resident on the South Arm of the Fraser River in summer. Current waterfowl harvesting by Tsleil-Waututh members in or near the Project area was not identified in sources reviewed.

The proposed Project has the potential to affect hunting and trapping through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred hunting and trapping locations by Tsleil-Waututh as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for hunting and trapping by Tsleil-Waututh during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to hunting and trapping locations by Tsleil-Waututh from instream construction activities, are expected to be negligible. While it is acknowledged that Tsleil-Waututh has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for hunting and trapping by Tsleil-Waututh resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with hunting and trapping locations.

Mitigation measures identified in the marine mammal and terrestrial wildlife assessments are expected to be effective at addressing potential effects on the availability of hunting and trapping resources preferred by Tsleil-Waututh. Therefore, Project-related effects on hunting and trapping related to potential changes in the availability of resources would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for hunting and trapping by Tsleil-Waututh; therefore, Potential Project-related effects on Tsleil-Waututh fishing would be expected to be negligible.

Project operation is not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when hunting and trapping are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** to address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while hunting and trapping. At preferred hunting and trapping locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Tsleil-Waututh.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Tsleil-Waututh is hunting and trapping. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Tsleil-Waututh's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.7 Gathering

Tsleil-Waututh report harvesting berries, and specifically cranberries, while resident on the Fraser River historically. Current gathering activities by Tsleil-Waututh members in or near the Project area were not identified in sources reviewed.

The proposed Project has the potential to affect gathering through changes in access to preferred locations, changes in availability of preferred resources, changes in quality of preferred resources and changes in quality of experience when gathering.

Potential changes in access to preferred gathering locations by Tsleil-Waututh as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for gathering by Tsleil-Waututh during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to gathering locations by Tsleil-Waututh from instream construction activities, are expected to be negligible. While it is acknowledged that Tsleil-Waututh has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for gathering by Tsleil-Waututh resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with gathering locations.

Mitigation measures identified in the vegetation assessment to address Project-related effects on terrestrial vegetation are expected to be effective at addressing potential effects on the availability of resources for the exercise of Aboriginal Interests related to gathering. Therefore, Project-related effects on gathering related to potential changes in the availability of vegetation would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for gathering by Tsleil-Waututh; therefore, Potential Project-related effects on gathering related to potential changes in the quality of resources would therefore be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when gathering are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while gathering. At preferred gathering locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Tsleil-Waututh.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Tsleil-Waututh is gathering. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Tsleil-Waututh's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.8 Archaeology and Cultural Heritage Interests

Tsleil-Waututh have reported that all areas used for traditional purposes, such as fishing, hunting, and gathering, are regarded as sacred. They have explained that the landscape utilized for these purposes was shaped, in the very distant past, by the Transformers—or *Xáls*, *Xexá:ls*, or *Khaals*—who began their journey at the Fraser River delta travelling upstream and creating the world.

The proposed Project has the potential to affect Tsleil-Waututh's Aboriginal Interests related to archaeology and cultural heritage through changes in access to preferred locations and changes in quality of experience.

Potential changes in access to locations related to Tsleil-Waututh's archaeological and cultural heritage interests as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations related to Tsleil-Waututh's interests related to archaeology and cultural heritage during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to locations related to Tsleil-Waututh's archaeological and cultural heritage interests from instream construction activities are expected to be negligible. While it is acknowledged that Tsleil-Waututh has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations related to Tsleil-Waututh's archaeological and cultural heritage interests resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and not expected to overlap with locations related to Tsleil-Waututh's archaeological and cultural heritage interests.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** would also be expected to address the potential Project-related effect to the quality of experience while undertaking activities related to cultural heritage. At locations related to Tsleil-Waututh's archaeological and cultural heritage interests that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Tsleil-Waututh.

As reported in **Section 6.1 Heritage Resources**, no archaeological or historical sites were identified within the Project area during fieldwork; however, there may be other locations with intangible cultural value or meaning to Tsleil-Waututh (e.g., spiritual or storied sites, named places) potentially affected by the Project. In addition, physical alterations to the landscape may affect archaeological or historical sites, and how this landscape is experienced culturally.

As a result, mitigation measures proposed in Part B are not expected to address a potential incremental and permanent Project-related effect tied to Tsleil-Waututh's Aboriginal Interests related to archaeology and cultural heritage that may be associated with the introduction of a new prominent feature to the cultural landscape. As this landscape has been previously modified by anthropogenic changes, the potential incremental Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal, but permanently disruptive for Tsleil-Waututh, who have identified a historical connection to, and continued or desired use of, sites or places that help define the cultural landscape in the Project area.

Additional mitigation to address this potential incremental effect that is not otherwise addressed in the Application is proposed in **Section 10.1.3.4** and summarized below under Mitigation.

5.0 Mitigation

This section provides a summary of mitigation measures identified to address potential Project-related effects on the exercise of Aboriginal Interests by Tsleil-Waututh. For a more detailed discussion, refer to **Section 10.1.3.4 Mitigation**.

Mitigation measures identified for the relevant VCs and ICs in Part B of the Application were reviewed to assess their effectiveness at addressing potential Project-related effects on the exercise of Aboriginal Interests related to those VCs. Examples of mitigation that are proposed in the Application to address potential effects on VCs and ICs, with the potential to result in an effect on Aboriginal Interests, include:

- Avoiding fisheries sensitive timing windows during key Project activities.
- Developing a Marine Access Management Plan to ensure marine use activities, including those supporting Aboriginal Interests, can continue during Project construction.
- Scheduling activities with the potential to generate underwater noise to avoid potential effects on marine mammals.
- Development and implementation of a Terrestrial Vegetation and Wildlife Management Plan with measures to minimize disturbance and loss of vegetation, prevent soil compaction, and minimize clearing in order to minimize effects on vegetation.

These measures are expected to be largely effective at avoiding, reducing, or otherwise managing potential Project-related effects on the exercise of Aboriginal Interests during Project construction and operation.

Recognizing some measurable effects on Tseil-Waututh's Aboriginal Interests could remain following the application of mitigation to address potential effects on the relevant VCs and ICs in Part B, the following additional measures have been identified to address such effects:

- Ongoing consultation with Tseil-Waututh regarding proposed measures, management plans, and monitoring programs related to intermediate components and valued components assessments; and
- Development of a Cultural Heritage Management Plan.

6.0 Residual Effects

With the implementation of mitigation measures identified in **Section 10.1.3.4** and summarized above, residual adverse effects of the proposed Project on the exercise of Aboriginal Interests are expected to be negligible (i.e., not measurable or detectable), and are not further assessed.

7.0 Summary and Conclusion

Part C of the Application builds on consultation undertaken to date to understand Tseil-Waututh's Aboriginal Interests and provides for an assessment of potential Project-related effects of the Project on Aboriginal Interests.

The Ministry began consultations with Tsleil-Waututh prior to the submission of the Project Description, which is the end of the Initial Consultation Phase. Both EAO and the Ministry consulted with Tsleil-Waututh during the Pre-Application Phase, which concluded with the submission of the Application. The main concerns expressed by Tsleil-Waututh during consultations include:

- Effects to fish and fish habitat, southern resident killer whales and benthic resources;
- Potential light and noise effects on wildlife and fish;
- Potential effects of the bridge structure on species such as waterfowl and migratory birds;
- Wetland assessment (ecological services, productivity and biodiversity), particularly with respect to at-risk amphibians;
- Habitat enhancement;
- Effects on the estuary and island complexes as well as Fraser River plume, particularly in relation to juvenile and returning salmon;
- Access to the Fraser River;
- Economic effects;
- Cultural assessment methodology;
- Capacity funding;
- Confidentiality of information sharing;
- Effectiveness of EAO-led process to address Tsleil-Waututh concerns;
- Social effects of the Project on Tsleil-Waututh Nation's ability to transfer knowledge, language and participate in socio-cultural practices;
- Absence of a comprehensive study of cumulative effects on the Fraser River and consideration of cumulative effects on Aboriginal rights;
- Project-related employment, training, contracting, and economic development opportunities;
- Use and disposal of dredged and other, material in the river as well as general concerns related to dredging of the Fraser River;
- Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations;
- Interest in climate change resiliency;
- Consideration of smart technologies in Project design;
- Interest in considering methods in addition to barriers, for suicide prevention;

- Interest in social determinants of health being assessed in the EA Application and Human Health being a VC;
- Potential effects of construction during fishing season on fishing activities. Impacts of Tunnel decommissioning on Aboriginal fisheries, specifically as it relates to timing;
- Change in flow rates after Tunnel removal;
- Impact of Project on Deas and Tilbury Sloughs and Duck, Barber and Woodward Island complexes;
- Traffic;
- Invasive plant management;
- Culturally significant plants;
- Stormwater management; and
- Water quality.

Based on information provided by Tsleil-Waututh and other publicly-available sources, the Ministry developed a summary of past, present and desired future use of the proposed Project area and its surroundings for the purposes of fishing, hunting/trapping, gathering, archaeology and cultural heritage interests and other related interests. This summary indicates that Tsleil-Waututh has, does and intends to continue to use the Fraser River for cultural purposes.

Relying first on the results of the effects assessments for related VCs and ICs in Part B, the assessment of potential effects of Tsleil-Waututh's Aboriginal Interests considered four indicators:

1. Access to preferred locations for the exercise of Aboriginal Interests;
2. Availability of preferred resources for the exercise of Aboriginal Interests;
3. Quality of preferred resources for the exercise of Aboriginal Interests; and
4. Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests.

As reviewed in **Section 10.1.3.3** and **Section 10.1.3.4**, the mitigation measures, management plans, and monitoring programs identified in Part B of the Application for ICs or VCs linked to the exercise of Aboriginal Interests are expected to be largely effective at addressing the incremental Project-related effects noted above on the exercise of Aboriginal Interests by Tsleil-Waututh Nation, except in the following potentially measurable cases:

- Project construction:
 - Potential temporary direct (minor) effect on quality of experience related to construction-related noise and a potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance
- Project operation:
 - Potential permanent direct (minor) effect on quality of experience related to traffic noise and a potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses
 - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses.

The following additional measures have been identified to address the above-noted effects:

- Ongoing consultation with Tsleil-Waututh regarding proposed measures, management plans, and monitoring programs related to IC and VC assessments; and
- Development of a Cultural Heritage Management Plan.

With the implementation of mitigation proposed to address potential effects on VCs and ICs, as well as additional mitigation proposed to address potential residual effects on Aboriginal Interests, no effects on the exercise of Aboriginal Interests by Tsleil-Waututh, as a result of the Project, are expected.

ENVIRONMENTAL ASSESSMENT PROCESS

An environmental assessment of the Project is required under the B.C. *Environmental Assessment Act* (B.C. *EAA*), S.B.C. 2002, c. 43, and permits to construct and operate can only be received once the environmental assessment process is complete and an Environmental Assessment Certificate (EAC) has been issued. If the Project is approved, an EAC will be awarded to and held by the Ministry. The Reviewable Projects Regulation B.C. Reg. 370/2002 under the B.C. *EAA* sets out the criteria for reviewable projects.

On December 16, 2015, the B.C. Environmental Assessment Office (EAO) issued a Section 10(1)(c) Order confirming that the Project is a reviewable project pursuant to the B.C. *EAA*, and that it requires an EAC.

The Project as proposed is not subject to review under the *Canadian Environmental Assessment Act, 2012*, S.C. 2012, c. 19, s. 52, since it does not meet the definition of a physical activity under the Schedule of Physical Activities in the Regulations Designating Physical Activities SOR/2012-147.

EAO is a neutral agency that manages the review of proposed major projects in British Columbia, as required by the *Environmental Assessment Act*.

ABORIGINAL INTERESTS

There are potential Project related impacts to Tsleil-Waututh's title, Rights and culture. Potential effects and the level of effect predicted include:

1. Access to preferred locations for the exercise of Aboriginal Interests (access to river locations for traditional use as a result of changes to physical characteristics of these locations).
2. Availability of preferred resources for the exercise of Aboriginal Interests (availability of fish, marine mammal, vegetation and terrestrial wildlife resources for Traditional Use).
3. Quality of preferred resources for the exercise of Aboriginal Interests (quality of water used for cultural purposes, quality of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use).
4. Quality of experience of exercising, or tied to the exercise, of Aboriginal Interests (quality of experience tied to the traditional use of river locations as a result of changes to the physical characteristics of the location; quality of experience tied to access of instream and upland areas locations for traditional use; quality of experience tied to use of water for traditional purposes; quality of experience tied to the traditional use of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use; and quality of experience while engaged in or tied to traditional use as a result of changes in air quality, noise, ground-borne vibration and to the cultural landscape).

Measureable Effects

Access for traditional use

- Cultural landscape
- Quality of experience while engaged in or tied to traditional use
- cultural landscape

No, Negligible or Moderate Effects

Quality of experience while engaged in or tied to traditional use

- Noise

Negligible Effects

Access for traditional use

- Instream locations
- River locations
- Upland locations

ABORIGINAL INTERESTS

Quality for Traditional Use

- Water
- Fish resources
- Marine mammal resources
- Vegetation resources

Quality of experience while engaged in or tied to traditional use

- Fish resources
- Instream locations
- Marine mammal resources
- River locations
- Terrestrial wildlife resources
- Upland locations
- Water
- Vegetation resources

Availability for Traditional Use

- fish resources
- Marine mammal resources
- Terrestrial wildlife resources
- Vegetation resources

No to Negligible Effects

Quality of experience while engaged in or tied to traditional use

- changes to the cultural landscape

No or Negligible Effects

Quality of experience while engaged in or tied to traditional use

- Air quality
- Ground-borne vibration

ABORIGINAL INTERESTS

High, Short-term Probability of Effect

- Disturbance to residential, commercial and industrial land uses
- Disturbance to recreational uses near the new bridge

Moderate, Long-term Probability of Effect

- Disturbance to visual quality

Low, Short-term Probability of Effect

- Barn swallow habitat loss (construction period)
- Physical injury or mortality to fish through crushing or entrainment (construction period)

Low, Long-term Probability of Effect

- Barn owl mortality

No Significant Residual or Cumulative Effects

- Air quality
- Fish and fish habitat
- Heritage resources
- Marine access
- Marine mammals
- River hydraulics and river morphology
- Sediment and water quality
- Terrestrial Wildlife
- Vegetation

The Ministry has developed mitigation measures to address these Potential effects. Residual effects on the exercise of Aboriginal Interests by Tseil-Waututh as a result of the Project are not expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|------------------|---|
| <p>Protection of Tsleil-Waututh Nation’s rights to harvest within the Project area.</p> | <p>Tsleil-Waututh’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures outlined in Table 10.3-1 and Section 10.1.3.4, residual effects on the exercise of Aboriginal Interests by Tsleil-Waututh as a result of the Project are not expected.</p> | <p>Addressed</p> | <p>Ongoing consultation and implementation of mitigation measures</p> |
| <p>Tsleil-Waututh Nation’s access to the Fraser River and the potential to displace fishing vessels. Potential interference with Aboriginal fisheries during decommissioning of the Tunnel and the importance of working closely with communities to ensure negative effects are avoided.</p> | <p>Tsleil-Waututh Nation’s access to the Fraser River and the potential to displace fishing vessels (access to river locations for traditional use as a result of changes to physical characteristics of these locations) is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined. A negligible effect on access to instream locations for traditional use and a negligible effect to upland locations for traditional use has been determined.</p> | <p>Addressed</p> | <p>Ongoing consultation and implementation measures outlined in Section 5.2.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|---------------------------------|---|
| <p>Social effects of the Project such as Tsleil-Waututh Nation’s knowledge transmission, language loss, dependency and social interaction.</p> | <p>Social effects of the Project on Tsleil-Waututh’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3.8 and Section 10.3 of Part C of the Application.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in all Sections of the Application</p> |
| <p>Cumulative effects:</p> <ul style="list-style-type: none"> • Consideration of cumulative effects on Aboriginal rights. • Assessment of cumulative effects in regards to the inclusion of other reasonably foreseeable projects and activities. | <p>The Application will include historical context as outlined relating to changes in use over time by Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by First Nations or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental</p> | | |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------|-------------------------|
| <ul style="list-style-type: none"> Absence of a comprehensive study of cumulative effects on the Fraser River | <p>cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests.</p> <p>The Ministry’s cumulative effects assessment looked at potential incremental environmental effects of construction and operation of the Project in conjunction with other present and reasonably foreseeable projects that could interact with the potential effects of this Project. The process and methodology used to conduct the cumulative effects assessment, including the identification of potential cumulative effects, identification of additional mitigation measures, and evaluation of any (residual) cumulative effects is outlined in Part B of the Application. Other Projects that are considered in the assessment of Project-related cumulative effects are also listed.</p> <p>While the Ministry acknowledges that Teleil- Waututh Nation is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project.</p> | | |

| ABORIGINAL CONSULTATION | | | |
|---|---|---------------|---|
| <p>Aboriginal Interests, defined as asserted or determined Aboriginal rights, including title, and treaty rights, are known to overlap or lie in the vicinity of the Project corridor. Potential adverse effects on the exercise of Aboriginal Interests as a result of Project construction and operation have been identified.</p> <p>Mitigation measures to address potential Project-related effects on intermediate components (ICs) and valued components (VCs) associated with the exercise of Aboriginal Interests are expected to be effective. With the application of mitigation, potential effects on the exercise of Aboriginal Interests are predicted to be negligible except in specific cases during Project construction and operation. To address potential effects during Project construction and operation, the development of an Archaeological and Heritage Resources Management Plan is proposed.</p> <p>In addition to mitigation measures proposed to address potential effects on ICs and VCs, ongoing engagement between the Ministry and Schedule B Aboriginal Groups will be undertaken. Such engagement will take place during Application Review and, if the Project is approved, following the issuance of an Environmental Assessment Certificate (EAC). Engagement will involve consultation on management plans and monitoring programs, related to the exercise of Aboriginal Interests.</p> <p>Ongoing engagement is also proposed to address other matters of environmental, economic, social, heritage, and health concern raised Aboriginal Groups during the pre-Application period. With this ongoing engagement, residual effects on the exercise of Aboriginal Interests or other matters of concern as a result of the Project are not expected.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Capacity funding to facilitate participation in the Project review process | Tsleil-Waututh Nation received funding for the Pre-Application Phase. The Ministry will provide further funding for the Application Review Phase. | Addressed | Consultation regarding funding for the Application Review Phase |
| Appropriate use of information shared by Tsleil-Waututh Nation as it relates to confidentiality and dissemination | The Ministry understands and respects that certain information shared by Tsleil-Waututh Nation may be considered confidential. The Ministry is subject to the provisions of the Freedom of Information and Protection of Privacy Act. However, subject to the requirements of applicable laws, the Ministry will respect Tsleil-Waututh Nation requests to keep information confidential. | Addressed | Appropriate use of confidential information |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|-----------|-------------------------|
| Funding for Knowledge Study | The Ministry signed a funding agreement with Tsleil-Waututh Nation which provided funding for a Knowledge Study. | Addressed | None |
| Input into areas for potential habitat enhancement | Request noted. The Ministry will consult with Tsleil-Waututh and other Aboriginal groups. | Noted | Ongoing consultation |
| Importance of working with Tsleil-Waututh in accordance with their stewardship policy | Noted and considered in planning for consultation with Tsleil-Waututh. | Noted | Ongoing consultation |
| Importance in distinction between consultation and information sharing | Importance in distinction between consultation and information sharing was addressed in the Aboriginal Consultation Plan. | Addressed | None |

ABORIGINAL PARTICIPATION AND PROJECT RELATED OPPORTUNITIES

The Ministry is actively exploring opportunities to provide benefits, economic and non-economic, to Aboriginal Groups that are directly affected by the Project. Opportunities include employment, training, and contracting as well as participation in environmental enhancement and other components of the Project.

Prior to the Pre-Application Phase of the Project, the Ministry worked with Schedule B Aboriginal Groups to determine appropriate tools to support consultation. Consultation activities were based on the specific needs and preferences of these Aboriginal Groups and the Consultation Plan included individualized plans that were co-developed and reviewed.

The Project's Aboriginal Consultation Plan has been developed in consultation with Schedule B Aboriginal Groups, in order to meet the Aboriginal consultation requirements as delegated by EAO and to maintain and, where possible, enhance positive working relationships between the Ministry and the respective Aboriginal Groups.

The objectives and requirements of the Aboriginal Consultation Plan are to:

- Provide relevant Project-related information in a timely and effective manner that supports an understanding of the nature of the Project and its potential adverse effects on Aboriginal Interests
- Plan and implement mutually acceptable consultation activities that support effective participation of Aboriginal communities in the EA as well as related regulatory and permitting processes
- Establish and maintain dialogue throughout the EA as a means of providing opportunities to respond to outstanding concerns
- Provide opportunities for Aboriginal Groups to share views of the Project with the Ministry and EAO within reasonable timeframes
- Provide opportunities for Aboriginal Groups to identify potential adverse effects of the proposed Project on Aboriginal Interests, including cumulative effects and, to the extent appropriate, develop ways to mitigate or otherwise accommodate potential adverse effects
- Involve Aboriginal Groups, where possible, in relevant studies including, but not limited to, archaeological fieldwork.
- Incorporate community and traditional knowledge in Project components

Document and report to EAO on the Ministry's Aboriginal consultation program at times specified by EAO.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|-----------|--|
| Opportunities for cultural recognition and naming | The Ministry is exploring opportunities for cultural recognition and naming and will work with Tsleil-Waututh on this matter. | Ongoing | Discussion with Tsleil-Waututh to explore opportunities related to cultural recognition and naming, art and interpretive signage |
| Project-related employment, training, contracting, and economic development opportunities. | The Ministry is committed to working with Tsleil-Waututh to identify potential opportunities to benefit from the Project. Ministry acknowledges that Aboriginal Groups want to prepare their membership for employment opportunities and will work with Tsleil-Waututh to identify ways to support community preparedness. | Ongoing | The Ministry will share information as it becomes available to support community preparedness and welcomes input from Aboriginal Groups on the type of information that would be useful. |
| Revenue sharing opportunities from tolling | Revenue from tolling is only used to defray the costs of designing, constructing, operating and maintaining highways. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application. | Addressed | None |

4.1 RIVER HYDRAULICS

The proposed bridge will have a clear-span, which eliminates potential changes to river hydraulics or river morphology resulting from the new structure. The Fraser River South Arm is dynamic with scour in the order of several metres during freshet and migrating sand dunes with heights of up to four metres. Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. Tunnel removal is expected to result in temporary bed lowering between the Tunnel and Lulu Island-Delta water main; however, no permanent effect on the Lulu Island-Delta watermain is expected.

Effects

A negligible effect to access to river locations for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of river locations has been determined.

Mitigation

Monitor the riverbed within 100 metres upstream and downstream of the watermain.

Stockpile appropriately-sized rock near the Project site, for priority scour protection repairs at the water main crossing.

Establish on-call contracts with a qualified registered professional and a qualified marine contractor prior to Tunnel removal, to ensure that scour protection repairs can be designed and implemented on short notice

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|---------------------------------|--|
| <p>Change in flow rates after Tunnel removal</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects to river hydraulics and river morphology within the Fraser River South Arm.</p> <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor.</p> <p>River Hydraulics and River Morphology are addressed in Section 4.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4</p> |
| <p>Impact of Project on Deas and Tilbury Sloughs and Duck, Barber and Woodward Island complexes</p> | <p>Deas and Tilbury Sloughs and Duck, Barber and Woodward Island complexes are included in Section 4.1 of the Application.</p> <p>Removal of the Tunnel is not expected to have long term effects on Deas and Tilbury Sloughs and Duck, Barber and Woodward Island complexes.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4</p> |

4.2 SEDIMENT AND WATER QUALITY

The proposed bridge will have a clear-span, which reduces potential effects to sediment and water quality within the Fraser River South Arm. During Tunnel decommissioning, a minor, temporary increase in turbidity, as compared with baseline conditions, is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.

Effects

A negligible effect on quality of water used for cultural purposes has been determined.

A negligible effect on quality of experience tied to use of water for cultural purposes has been determined.

Mitigation

Avoid effects through Project design.

Incorporate a stormwater collection and distribution system (stormwater detention ponds and biofiltration swales) into bridge design that will convey and discharge stormwater runoff to appropriate upland infrastructure for proper treatment.

Develop Construction Environmental Management and Operational Environmental Management plans.

Control suspended sediment during Tunnel decommissioning. Employment of construction methods that minimize levels of Project-induced turbidity. Use spoil barges equipped with sediment containment system (filter cloth, concrete lock blocks, straw bales) to transport removed material off-site.

Control suspended sediment during Project construction in and adjacent to Deas and Green Sloughs. Use of sediment control measures such as turbidity curtains and de-watered cofferdams.

Monitor water quality during construction.

Use timing windows for undertaking in-stream works.

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology or sediment and water quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------------------------|--|
| <p>Potential effects of run off and drainage - innovative stormwater solutions and bioengineering techniques</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciative change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected.</p> <p>Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.2.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|------------------|-------------------------|
| <p>Water quality and sediment issues: comprehensive understanding of potential ecological impacts and core sampling</p> | <p>Changes in sediment riverbed characteristics that have the potential to affect receptor VCs include changes in sediment composition and organic carbon content, and changes in sediment quality in terms of contaminant concentrations. Similarly, changes in the water column that have the potential to affect receptor VCs include changes in total suspended solids (TSS) and turbidity levels, or changes in ambient water chemistry. Therefore, Project-related study of water and sediment quality was designed to focus on these aspects. A literature review, gap analysis, and field program, as outlined in Table 4.2-1, were undertaken to establish existing conditions, and sediment fate predictions described in Section 4.1 River Hydraulics and River Morphology were used to identify potential Project-related effects of water quality and sediment quality in the Fraser River South Arm, Deas Slough, and Green Slough.</p> | <p>Addressed</p> | <p>None</p> |

4.4 FISH AND FISH HABITAT

The proposed bridge will have a clear span over the Fraser River South Arm and Deas Slough, avoiding or minimizing Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Given the disturbed nature of much of the Project alignment, re-vegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by improvements to local water quality; removal of non-native species; and replanting with species that provide habitat value for fish and wildlife.

Effects

- A negligible effect on the availability of fish resources for traditional use has been determined.
- A negligible effect on quality of fish resources for traditional use has been determined.
- A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

Mitigation

- Avoid effects through Project design.
- Apply best management and environmental management practices.
- Develop Construction Environmental Management and Operational Environmental Management plans.
- Use timing windows for undertaking in-stream works.
- Erosion and sediment control.
- Habitat enhancement and offsetting.

Residual & Cumulative Effects

- There is a low, short-term probability of physical injury or mortality to fish through crushing or entrainment during the construction period.
- No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|-----------|---|
| Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon | The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon and salmon. Potential Project-related effects on fish and fish habitat are presented in Section 4.4 of the Application. | Addressed | Implementation of mitigation measures outlined in 4.4.4 |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|-----------|---|
| Species of salmon | The Ministry will work with the BC Environmental Assessment Office to ensure that the methodology used to support the assessment of environmental values is consistent with current best practice and guidance materials that support the assessment of projects under the BC Environmental Assessment Act. | | |
| Evaluation on impacts to ecological services for all ecosystems within the vicinity of the Project | Pacific salmon species selected for Project-related baseline studies include Chinook salmon, Chum salmon, Coho salmon, Pink salmon, and Sockeye salmon. Using existing scientific and literature, baseline conditions will be described for all life history stages of each salmon species, with emphasis on those life history stages that use aquatic habitats within the Project Area. Fish sampling focused on potential rearing values within drainage ditches in Richmond and Delta, for which limited existing inventory information exists, has been incorporated into the baseline studies. | Addressed | Implementation of mitigation measures outlined in 4.4.4 |
| Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon | Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources can be mitigated effectively by scheduling such activities during periods of low tide, when work can be completed under shall water conditions or in the dry, thereby minimizing potential effects. No Project- | Addressed | Implementation of mitigation measures outlined in 4.3.4 and 4.4.4 |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|------------------|--|
| | <p>related residual or cumulative effects on underwater noise conditions are expected. Underwater Noise and Fish and Fish Habitat are addressed in Sections 4.3 and 4.4 of the Application.</p> | | |
| <p>Disturbance to benthic and aquatic invertebrates and their habitat</p> | <p>Aquatic habitats, which include habitat for fish and other aquatic species (including benthic and aquatic invertebrates), will be a primary area of focus for the environmental assessment of the Project.</p> <p>Potential disturbance to benthic and aquatic invertebrates is not, on its own, proposed as a key area of study given the nature of the project and the aquatic habitats it overlaps with. Aquatic habitats overlapping with the Project occur within a section of the Fraser River that is dynamic, influenced by large flow variations and downstream transport of sand and organic matter. Therefore, aquatic and benthic invertebrate communities in the Project Area are expected to be resilient to physical disturbance. Given the temporary and short-term changes in flow and water quality expected from Project activities, it is anticipated that the benthic and aquatic invertebrates will recover rapidly from disturbance.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in 4.3.4 and 4.4.4</p> |

4.6 MARINE MAMMALS

Marine mammals, specifically harbor seals and sea lions, are known to use marine areas within the Project alignment. Other species of conversation interest, including southern resident killer whales, do not occur in the Fraser River. Underwater noise during construction is the key area of focus for potential Project-related effects on marine mammals. Underwater noise in the Fraser River South Arm from existing sources currently exceeds thresholds for disturbance to marine mammals approximately 20% of the time. The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.

Effects

A negligible effect on the availability of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of marine mammal resources for traditional use has been determined.
 A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

Mitigation

Apply standard industry and best management practices to activities such as impact pile driving that have the potential to generate underwater noise to ensure sound thresholds for the protection of marine mammals are adhered to.
 Monitor underwater noise.

Cumulative Effects

No significant Project-related residual or cumulative effects on marine mammals are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|-----------|-------------------------|
| Effects on southern resident killer whales within 10 km of Project area | The Project is not anticipated to affect southern resident killer whales (SRKW). Based on the results of underwater noise modelling completed to date, underwater noise generated by Project-related activities is not predicted to extend outside of the Fraser River, and therefore will not affect SRKW. In addition, studies completed to date also indicate that SRKW prey (i.e., chinook salmon) in the Fraser River is not likely to be affected by the Project at a level that could affect the survival or recovery of SRKW. | Addressed | None |

4.7 VEGETATION

The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development.

Project components and activities will be primarily located within the existing Highway 99 right-of-way, where the vegetation consists mainly of grassy, mowed verges. Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary marsh that occur in the vicinity of the Project. No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.

Effects

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to best management and environmental, terrestrial vegetation and wildlife management practices. Apply best practices such as flagging of at-risk ecosystems to avoid encroachment during construction.

Offset and enhance habitat. Create comparable habitat within the Project alignment to offset unavoidable potential Project-related effect, limited to a small reduction in area of the cattail marsh that overlaps with Project components. Replant disturbed areas with native species.

Invasive species management.

Cumulative Effects

No significant Project-related residual or cumulative effects on vegetation are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|-----------|---|
| Invasive plant species and proposed plans to manage presence during construction | Mitigation and management of invasive species are presented in Section 4.7 of the Application. The Ministry will develop and implement an Invasive Species Management Plan as part of the Construction Environmental Management Plan. | Addressed | Implementation of mitigation measures outlined in Section 4.7.4 |
| Culturally significant plants should be used in planting plans | Planting plans will be developed during later stages of Project planning and design. Opportunities for inclusion of culturally significant plants in in planting plans will be considered at that time. The Ministry will consult Aboriginal Groups on the development of these plans. | Addressed | The Ministry will develop planting plans with consultation from Aboriginal Groups |

4.8 TERRESTRIAL WILDLIFE

The Highway 99 corridor is a highly developed area and terrestrial wildlife has generally adapted to this current condition. Terrestrial wildlife along Highway 99 consists primarily of raptors, riverine birds, and small mammals. Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge. No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.

Effects

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to terrestrial vegetation and wildlife management best practices such as spatial and temporal avoidance, pre-construction surveys and nest survey protocols, wildlife salvage and translocation, flagging and management of sensitive areas, and timing window restrictions.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term probability of barn swallow habitat loss during the construction period. The new bridge will provide new nesting opportunities for barn swallows.

There is a low, long-term probability of barn owl mortality.

No significant Project-related residual or cumulative effects on terrestrial wildlife are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|------------------|--|
| <p>Potential light and noise effects on wildlife and fish.</p> | <p>The Ministry understands that Tsleil-Waututh is concerned with the potential effects of light and noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |
| <p>Potential effects of the bridge structure on species such as waterfowl and migratory birds.</p> | <p>The Ministry understands that Tsleil-Waututh is concerned with the potential effects of the new bridge structure on species such as mammals, waterfowl, bats, eagles and migratory birds. Installation of flight deflectors such as hedgerows at appropriate locations along the highlight will mitigate potential Project-related increase in traffic collision risk. Terrestrial Wildlife in addressed in Section 4.8 of the Application.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|------------------|--|
| <p>Wetland assessment (ecological services, productivity and biodiversity), particularly with respect to at-risk amphibians</p> | <p>At-risk amphibians were not detected within the Project alignment during field studies undertaken in 2014 and 2015. The potential for at-risk amphibians to occur within the Project alignment is low. Applying mitigation, including least-risk timing windows, and adherence to standard practices for undertaking in-stream works and highway maintenance activities, will ensure that Project-related effects on at-risk amphibians are addressed.</p> | <p>Addressed</p> | <p>Implementation of mitigation measures outlined in Table 4.5-6</p> |
| <p>Protection of large mammals including black-tail deer and clarification of WARS on Project area</p> | <p>The Wildlife Accident Reporting System (WARS) contains long-term wildlife-related accident records that provide wildlife data for a range of purposes, including highway planning (Sielecki 2003). Data collected through WARS helps improve understanding of where wildlife mortality is occurring such that measures can be taken to avoid or reduce such mortality. WARS data are primarily collected by highway maintenance crews.</p> <p>Due to previous development in areas directly adjacent to the existing right-of-way, habitat features for deer are absent. As such, large mammals have not been included as a valued component in the environmental assessment for the Project.</p> | <p>Addressed</p> | <p>None</p> |

4.9 AIR QUALITY

Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in.

Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include a 35% reduction in particulate matter emissions, as compared with a 14% reduction without the Project; a 47% reduction in volatile organic compound emissions, as compared with a 40% reduction without the Project; and no exceedances of the current most stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.

The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.

Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.

Effects

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

Mitigation

Minimize effects through Project design.

Implement recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.

Development of an Air Quality and Dust Control Management Plan for inclusion of the Construction Environmental Management Plan.

Measure and monitor vehicle emissions and road dust during Project operation.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------|----------------------------------|
| Interest in climate change resiliency and a request for review with the Ministry when forms are complete | The Ministry has committed to sharing this information when available | Addressed | Share information when available |

4.10 ATMOSPHERIC NOISE

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the highway but do not exceed what is acceptable for residential, educational or institutional facilities.

Effects

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

Mitigation

Minimize effects through Project design.

Adhere to construction best practices and the Ministry’s 2014 *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways*.

Develop and implement a Noise Management Plan.

Residual & Cumulative Effects

With the application of mitigation, no significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Tsleil-Waututh has not voiced any specific issues or concerns with respect to Atmospheric Noise. | | | |

5.2 MARINE USE

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, and sorting and booming, as well as commercial, recreational and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place within the vicinity of the Project.

A clear span crossing of the Fraser River is proposed to avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span to improve navigation in and out of the slough.

Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.

Effects

A negligible effect on access to instream locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Develop and implement a Marine Access Management Plan to ensure that important marine use activities can be reconciled with temporary constraints associated with Project construction.

Establish communications protocols to advise in-stream construction activities.

Ensure appropriate lighting and marking for safe navigation.

Establish navigation protection zones during construction to avoid or minimize impact on marine use.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|--------------------------|---|
| Potential effects of construction during fishing season on fishing activities | <p>Potential interference with fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> <p>The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided.</p> | Addressed in Application | Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4 (Marine Use Mitigation Measures) |
| Impacts of Tunnel decommissioning on Aboriginal fisheries, specifically as it relates to timing | <p>Potential interference with fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> <p>The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided.</p> | | Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4 (Marine Use Mitigation Measures) |

5.3 LAND USE

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta.

The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect regional growth trends or current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.

Once the new bridge becomes operational, recreational experience in its vicinity is expected to change due to improvements in local air quality, shoreline restoration of Deas Island, and re-vegetation of areas currently supporting highway infrastructure; improved connectivity across the Deas Island Regional Park resulting from removal of the Tunnel portals; and shading adjacent to the bridge, overhead noise, and changes in local viewscales.

The Project will not result in changes to existing land use beyond small amounts of land, outside of the existing right-of-way, that area required for the Project.

Effects

Negligible effect on access to upland locations for traditional use

Negligible effect on quality of experience tied to access of upland areas for traditional use.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|------------------|---|
| <p>Impacts of staging/laydown areas. Request that the Ministry provide construction parameters to avoid impacting areas around Project footprint.</p> | <p>The Application has been developed with the assumption that all temporary and permanent works will be included within the Project alignment. Potential staging areas that will be made available to the contractor encompass areas within the highway right-of-way that have been previously developed and disturbed.</p> <p>Any temporary or permanent works that are to take place will be subject to applicable permitting requirements, including <i>Water Sustainability Act</i> permitting and archaeological investigation if required. Applications for these permits will include detailed descriptions and locations of works to take place.</p> <p>If the contractor chooses to develop staging areas on sites other than those identified, site-specific environmental permitting and approvals will be obtained by the contractor.</p> | <p>Addressed</p> | <p>Contractor will obtain permits and approvals as required</p> |

5.5 VISUAL QUALITY

The new bridge will add noticeable visual features to the landscape and will change visual conditions adjacent to the Project alignment. Replacement of interchanges also has the potential to change visual conditions of these locations. At distances greater than one kilometer, the bridge deck will merge with the natural landscape and the main visual features will be the bridge towers. Changes in visual quality at interchanges will be minor as visual quality in such areas is currently influenced by existing transportation infrastructure.

Effects

During construction: No to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

During operation: A measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Minimize effects through Project design.

Use of vegetated buffers to minimize visual effects to residential developments within close proximity to the bridge in Delta.

Residual & Cumulative Effects

There is a moderate, long-term probability of disturbance to visual quality.

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Tsleil-Waututh Nation has not voiced any specific issues or concerns with respect to Visual Quality. | | | |

| 6.1 HERITAGE RESOURCES | | | |
|---|---|---------------------------------|---|
| <p>The Project is located in an area where substantial historical development has occurred and the majority of the Project alignment is characterized as having low archaeological potential. No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.</p> <p><u>Effects</u> A negligible effect on access to upland locations for traditional use has been determined. A negligible effect on quality of experience tied to access of upland locations for traditional has been determined. During construction: No to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape. During operation: A measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.</p> <p><u>Mitigation</u> Develop and implement a Heritage Resources Management Plan, which will include a change find procedure, to avoid impacts to previously unknown heritage resources that may be encountered during Project construction and operation. Undertake additional archaeological surveys.</p> <p><u>Residual & Cumulative Effects</u> No significant Project-related residual or cumulative effects on heritage resources are expected.</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| <p>Protection of archaeological and heritage resources, including intangible heritage sites.</p> | <p>Ministry acknowledges that protection of archaeological sites as well as intangible heritage sites are of utmost importance to Tsleil-Waututh Nation.</p> <p>All Aboriginal Groups have been provided with a comprehensive list of these sites, the Archaeological Overview Assessment, the Archaeological Impact, and Heritage Resources Overview Assessment.</p> <p>Appropriate measures will be taken to ensure the protection of archaeological and heritage resources as outlined in Section 6.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures as outlined in Section 6.1.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|-----------|--|
| Participation in archaeological fieldwork and review of archaeological draft reports | Tsleil-Waututh Nation participated in all archaeological field work to date and was provided the opportunity to review draft archaeological reports. | Addressed | Tsleil-Waututh Nation will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports. |
| Request that First Nations permits be obtained before the commencement of archaeological work | First Nations heritage permits were obtained by the archaeologist in advance of work commencing. | Addressed | Obtain permits as required |

7.0 HUMAN HEALTH

Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health. The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options. The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased active and public transportation, improved traffic safety, improvement connectivity and access, improved emergency response, and economic development opportunities.

Future Project-related consultation with Aboriginal groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.

Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations, and emergency response.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

A negligible effect on access to instream locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

7.0 HUMAN HEALTH

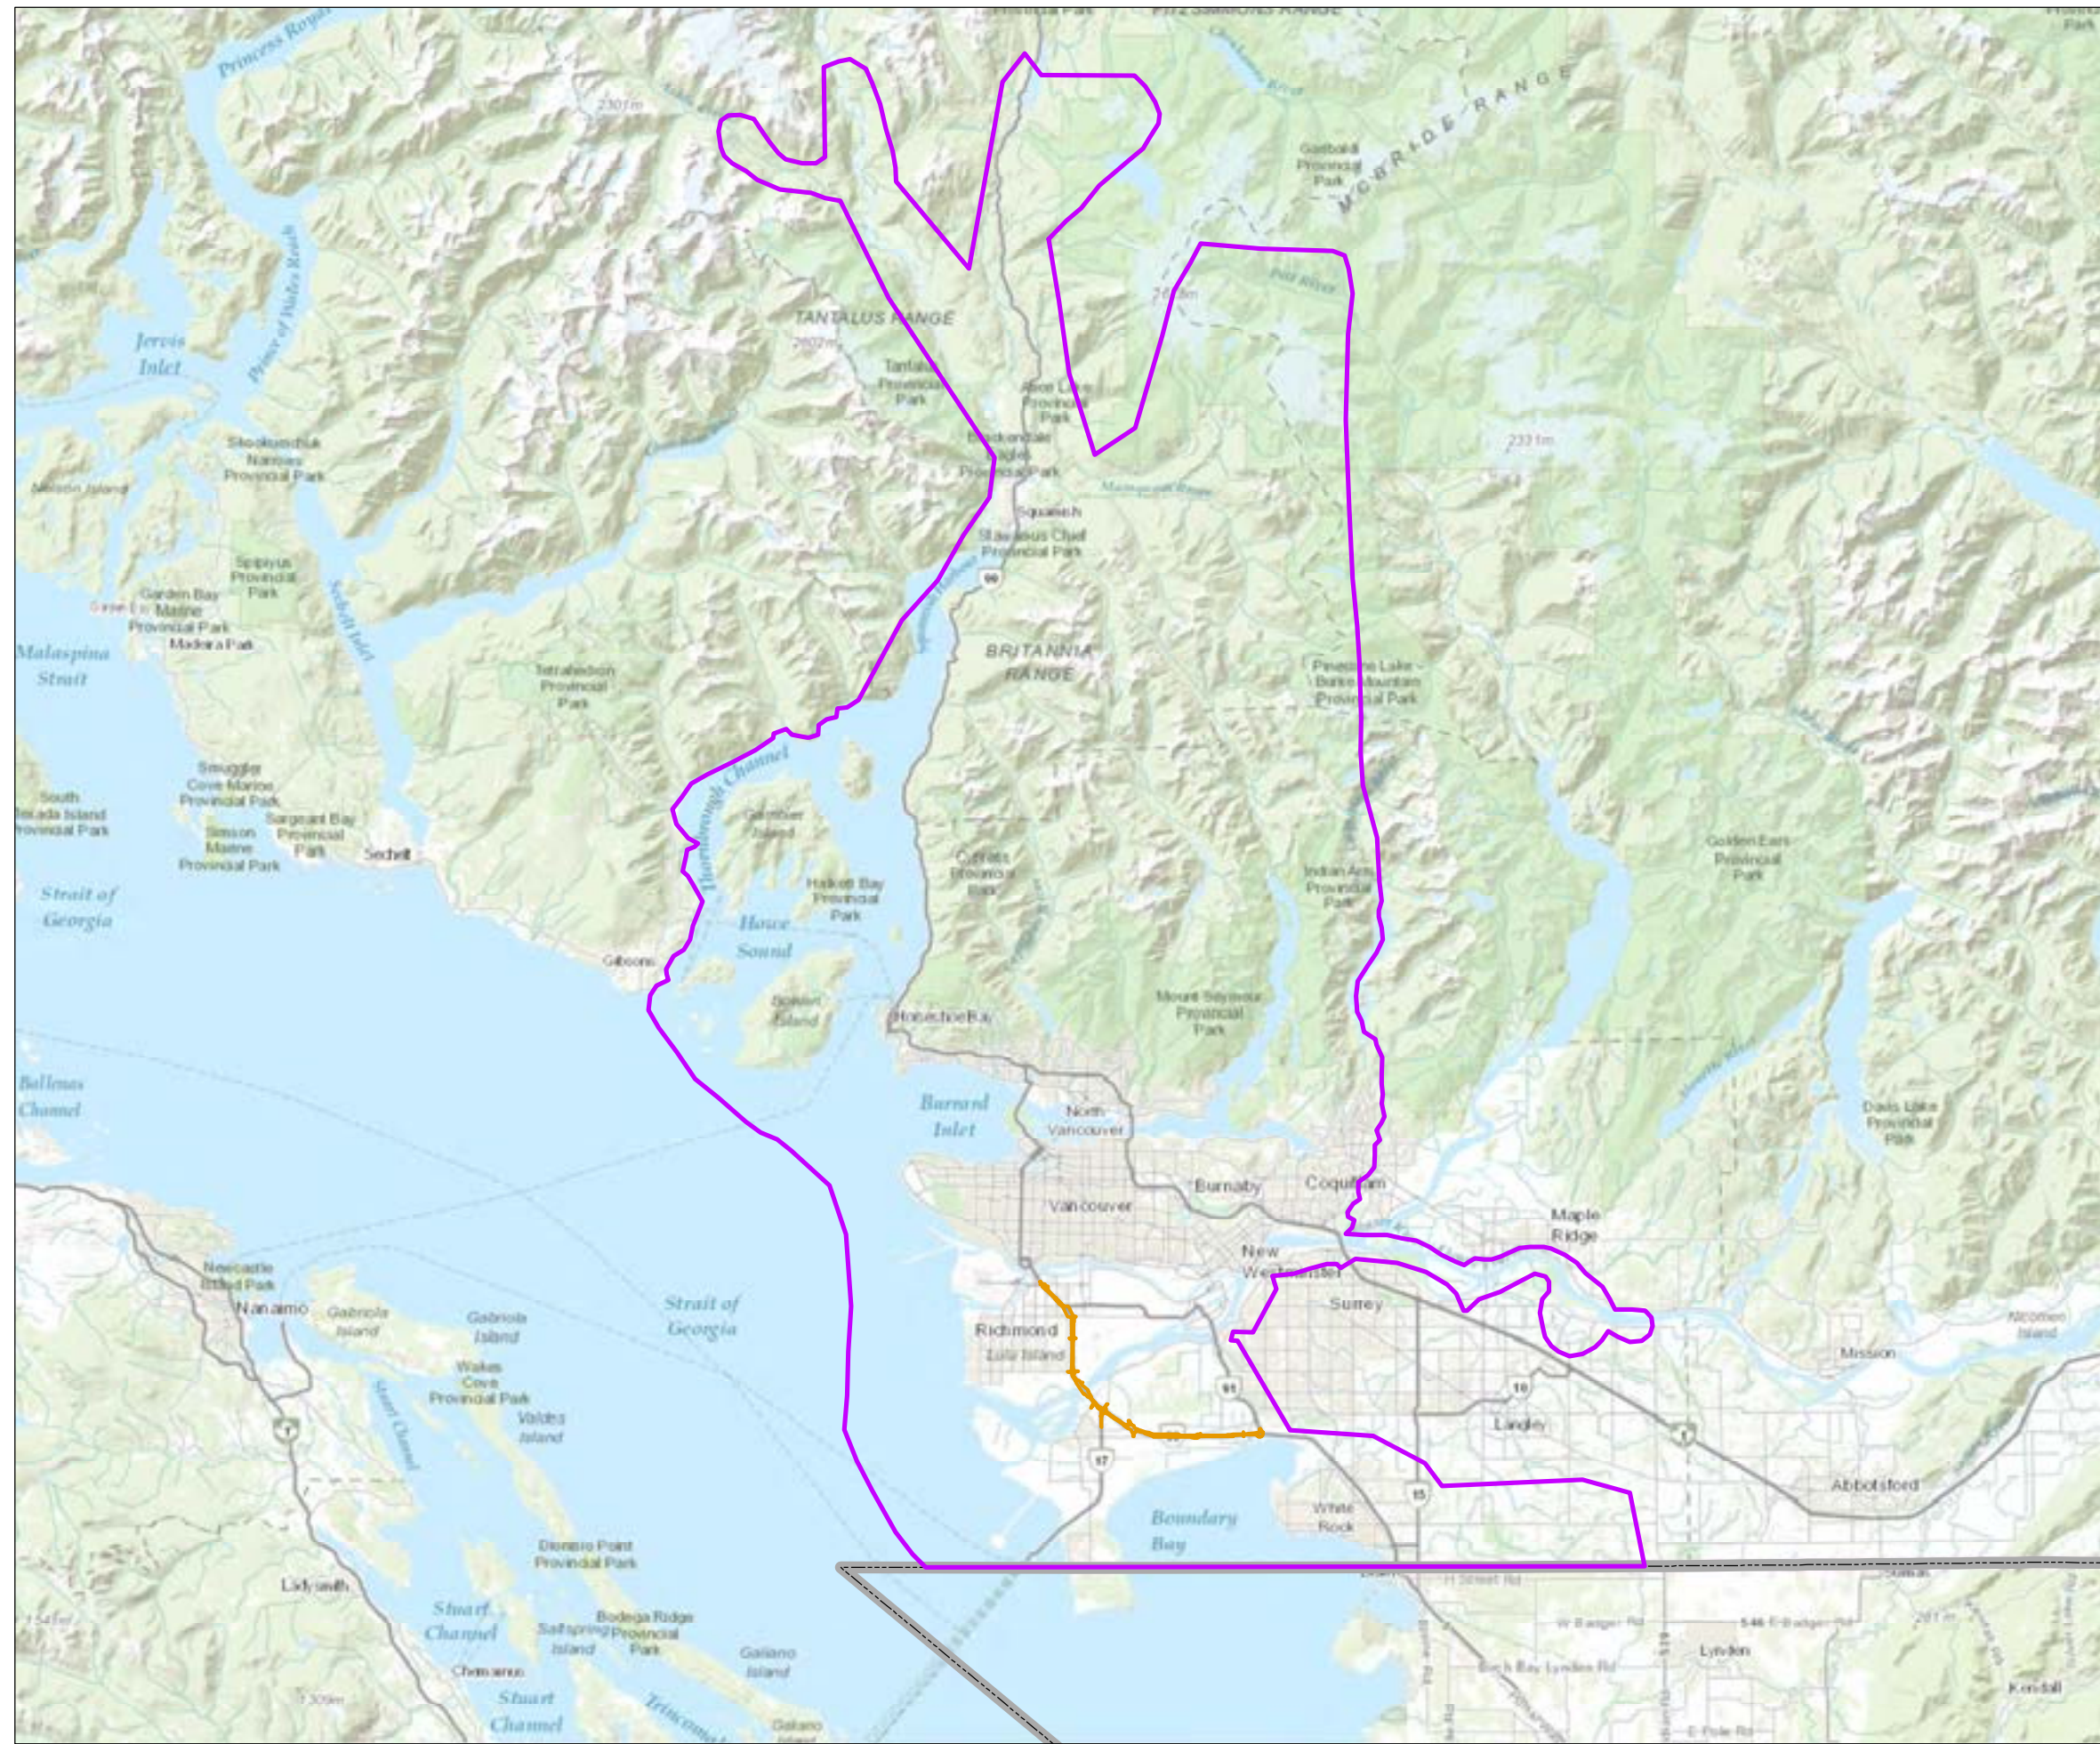

A negligible effect on access to upland locations for traditional use has been determined.
 A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.
Mitigation
 Implement proven mitigation measures, effectively used during construction of projects such as the South Fraser Perimeter Road and Port Mann / Highway 1 Improvement, to ensure that temporary increases in ambient noise levels and air emissions during construction do not result in health effects.
 Implementation of mitigation measures outlined in Fish and Fish Habitat, Marine Mammals, Vegetation, Terrestrial Wildlife, Air Quality, Atmospheric Noise, Marine Use and Land Use.
Residual & Cumulative Effects
 No significant Project-related residual or cumulative effects on human health are expected.

| Issue | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------------------------|--|
| Interest in considering methods in addition to barriers, for suicide prevention | The Ministry is in the process of developing a policy in which new bridges in the Lower Mainland will require the installation of safety barriers. The Ministry is committed to including safety barriers as part of the design of the new bridge and will continue to discuss additional measures with Tsleil-Waututh. Assessment of potential Project-related effects on human health, including community and social factors, are presented in Section 7.1 of the Application. | Addressed in Application | Development of safety barrier policy for new bridges in the Lower Mainland. Implementation of mitigation measures outlined in Section 7.1 |
| Interest in social determinants of health being assessed in the EA Application and Human Health being a VC | Social determinants of health was considered in the assessment of potential Project-related effects on human health, including community and social factors. Human Health is addressed in Section 7.1 of the Application. | Addressed | None |

| 8.0 ACCIDENTS AND MALFUNCTIONS | | | |
|---|---|---------------|--|
| <p>Adherence to the practices and procedures contained in the Construction Environmental Management Plan will minimize the potential for accidents and malfunctions to occur.</p> <p>In general, replacement of the Tunnel with a new crossing and the proposed highway improvements are expected to lower the risk of accidents and malfunctions during highway operations and maintenance</p> | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations | An Emergency Response and Spill Contingency Plan will outline how construction personnel will prevent, prepare for, respond to, and clean up spills | Addressed | Implementation of mitigation measures outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan) |

| OTHER ISSUES | | | |
|--|---|---------------|---|
| Consultation with Tsleil-Waututh Nation identified issues outside of the environmental assessment process, Aboriginal Interests, Aboriginal Consultation, Aboriginal Participation and Project-Related Opportunities, and sections of the Application. | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Consideration of smart technologies in Project design | The Ministry is developing an Intelligent Transportation System Strategy for the Highway 99 corridor as part of the Project scope. Proposed infrastructure includes a fibre optic network connecting the highway to the Regional Transportation Management Centre, cameras providing coverage of the highway, vehicle detection sensors, changeable message signs and additional infrastructure to allow for expansion of the system as new technologies come into use. | Addressed | Development of Intelligent Transportation System Strategy |
| Length of time tolls are in place | The Province intends to fund the Project, at least in part, through user tolls. This is consistent with the provincial tolling guidelines. Tolling recognizes that those directly benefitting from the new infrastructure in terms of time savings and reliability should help pay for the Project. This ensures that the needed improvements can proceed now, rather than years in the future when improvements will be even more overdue. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application. | Addressed | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|------------------|-------------------------|
| <p>Use and disposal of dredged and other, material in the river as well as general concerns related to dredging of the Fraser River.</p> | <p>Dredging to deepen the river is not a component of this Project and the Ministry is unaware of any plans by others to dredge the river deeper. The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river. This is outlined in Sections 1.1.7.2 (Construction), 4.1 (River Hydraulics) and 4.2 (Water Quality and Sediment) of the Application.</p> | <p>Addressed</p> | <p>None</p> |
| <p>Consideration of traffic data from other proposed projects or regional studies</p> | <p>As outlined in Section 5.1.9, traffic data from a number of sources was considered.</p> | <p>Addressed</p> | <p>None</p> |

APPENDIX P

Hwlitsum

1.0 Introduction

This appendix provides a summary of the information presented in Part C Aboriginal Consultation (Part C) of the Application for an Environmental Assessment Certificate (the Application) regarding the assessment of effects on Aboriginal Interests. Aboriginal Interests are defined as asserted or determined Aboriginal rights, including title, or treaty rights. This appendix presents the information specific to Hwlitsum.

The organization of the information presented generally follows Part C and includes the following sections:

- Consultation;
- Community Profile;
- Existing Conditions;
- Potential Effects;
- Mitigation;
- Residual Effects; and
- Summary and Conclusion.

For more detailed information on the effects assessment on Aboriginal Interests related to Hwlitsum, refer to the following sections of Part C:

- Consultation with Hwlitsum (**Section 10.1.2.10**);
- Hwlitsum community profile (**Section 10.1.1.2**);
- Description of existing Hwlitsum Aboriginal Interests (**Section 10.1.3.2**);
- Assessment of potential effects of the Project on the exercise of Hwlitsum Aboriginal Interests (**Section 10.1.3.3**);
- Mitigation relating to potential effects on Aboriginal Interests (**Section 10.1.3.4**); and
- Residual effects on Hwlitsum Aboriginal Interests following application mitigation (**Section 10.1.3.5**).

A summary of Aboriginal Interests Assessment for Hwlitsum is also provided in **Section 10.1.3.8**.

The summary presented in this appendix also incorporated information found in the Hwlitsum Overview Table (**Appendix P2**), which provides detailed information regarding:

- Hwlitsum’s issues and concerns identified to date;
- Identification of potential effects on VCs and ICs that relate to the assessment of effects on Hwlitsum’s Aboriginal Interests;
- The Ministry’s response to specific issues and concerns raised by Hwlitsum;
- The status of these issues and concerns; and
- Next steps required to address outstanding issues and concerns.

2.0 Consultation

This section provides information regarding the consultation activities that the EAO and Ministry carried out prior to submission of the Application.

2.1 EAO-led Consultation Activities

2.1.1 Capacity Funding

When a provincial agency is a proponent of a project going through a provincial EA under the British Columbia *Environmental Assessment Act* (BCEAA), that agency provides funding to Aboriginal Groups to support their involvement in pre-Application and Application review phases in place of EAO providing such funding. The Ministry’s provision of capacity funding is discussed in the following section, Proponent-led Consultation Activities.

2.1.2 Participation in Working Group

EAO invited Hwlitsum and all other Aboriginal groups identified in Schedule B of the Section 11 Order to participate as members of a Working Group.

During the Pre-Application stage, Hwlitsum attended two EAO-led Working Group meetings where the Ministry presented information on the Project and the environmental assessment process and received and responded to comments on those presentations.

The first Working Group meeting, held January 2016, focused on the environmental assessment process, Project overview and update, Key Areas of Study, draft Application Information Requirements overview, and preliminary conclusions from study results.

The second working group meeting, held March 2016, focused on the environmental assessment process, list of materials available on the Project website, review of comments received on, and resulting changes to, the draft Application Information Requirements, and a description and rationale of the assessment areas. Working Group comments raised by Hwlitsum in relation to the draft Application Information Requirements resulted in Aboriginal groups being invited to participate in river-otter related fieldwork in April 2016. The objectives of this work were to document river otter presence or potential presence with the Regional Assessment Area, document and describe use of riparian and high use areas and identify potential Project-related effects.

Hwlitsum also participated in the completeness review of the Application that considered whether the Application included information requirements set out in the Application Information Requirements.

It is anticipated that Hwlitsum will continue as an active member of the Working Group through the environmental assessment process.

2.2 Proponent-led Consultation Activities

The Ministry began consultation with Hwlitsum in early 2014 in order to identify the nature and scope of Hwlitsum's Aboriginal Interests and how they might be impacted by the Project. Following is a summary of consultation activities led by the Ministry with Hwlitsum. A more detailed discussion is provided under the Hwlitsum section in **Section 10.1.2.10 Overview of Consultation with each Schedule B Aboriginal Group**. The following sections represent the main activities undertaken in support of Proponent-led consultation and include the following:

- Provision of capacity funding;
- Traditional use, traditional knowledge and other studies;
- Examples of Consultation Activities; and
- Concerns Identified to Date.

2.2.1 Capacity Funding

The Ministry entered into a Participation Funding Agreement, including the Initial Consultation and Pre-Application phases for consultation, with Hwlitsum. The Ministry has been working with Hwlitsum regarding their needs for capacity funding to facilitate their participation in the Application Review Phase. Consultation activities that are anticipated to be undertaken during the Application Review phase that will be supported by capacity funding include participation in technical reviews and analyses, involvement in ongoing consultation activities, and presentation of key information regarding their respective Aboriginal Interests.

2.2.2 Traditional Use, Traditional Knowledge & Other Studies

The Ministry provided additional funding to Hwlitsum for the preparation and submission of the traditional use study *Hwlitsum Traditional Use and Occupancy Study 2015*. The purpose of such studies is to identify Aboriginal input and traditional knowledge for inclusion and consideration in the EA. In addition, studies were funded to enhance the Ministry's understanding of Aboriginal Interests and Aboriginal Group's past, present and desired future use as it pertains to the exercise of Aboriginal Interests within the Project area and the potential adverse effects on identified Aboriginal Interests.

2.2.3 Examples of Consultation Activities

A number of consultation activities were undertaken with Hwlitsum during both the Initial Consultation Phase and the Pre-Application Consultation Phase as follows:

Initial Consultation Phase Activities - The Ministry recognized the importance and value of early engagement with Schedule B Aboriginal Groups and undertook an Initial Consultation Phase prior to the Pre-Application Phase. The Initial Consultation Phase concluded in December 16, 2015 with submission of Project Description. The focus of the Initial Consultation Phase was collection of baseline information and sharing of draft EA-related documents (i.e. Project Description and Key Areas of Study, draft Application Information Requirements (AIR)). The main consultation activities the Ministry undertook with Hwlitsum included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Hwlitsum;
- Funding for Hwlitsum's participation in Project consultation activities and EA process;
- Site visit;
- Review of draft EA documents such as the Project Description and Key Areas of Study, Heritage Resources Overview Assessment/Archaeological Overview Assessment, Heritage Resources Assessment and Aboriginal Consultation Plan;
- Meetings with Hwlitsum leadership, staff, consultants, and elders; and
- Response and follow up with Hwlitsum regarding the identification and resolution of issues.

Pre-Application Consultation Phase Activities - The Pre-Application Consultation Phase began with the filing of the Project Description and Key Areas of Study on December 16, 2015 and concluded with the submission of the Application. This phase included the issuance of Section 11 Order, AIR development and collection of baseline information. The main consultation activities the Ministry undertook with Hwlitsum included:

- Sharing of Project-related information including focused presentation on topics on interest and/or concern to Hwlitsum;
- Funding for Hwlitsum’s participation in Project consultation activities and EA process;
- Meetings with Hwlitsum leadership, staff, consultants, elders and membership;
- Hwlitsum participation in the EA Working Group;
- Review of draft EA documents such as the Application Information Requirements, Aboriginal Consultation Plan, and Aboriginal Consultation Reports; and
- Response and follow up with Hwlitsum regarding the identification and resolution of issues.

2.2.4 Concerns Identified to Date

As outlined above, Hwlitsum’s concerns, identified through consultation undertaken to-date, are presented in **Appendix P2 Hwlitsum Overview Table**. The Ministry’s response to Hwlitsum’s key concerns regarding potential impacts on Hwlitsum’s Aboriginal Interests are outlined below:

Table 1 Concerns Identified to Date

| Concerns Identified to Date | Response |
|---|--|
| <p>Protection of Hwlitsum’s rights to harvest within the Project area.</p> | <p>Hwlitsum’s rights to harvest within the Project area are addressed in Part C of the Application.</p> <p>With the implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife, residual effects on the exercise of Aboriginal Interests by Hwlitsum as a result of the Project are not expected.</p> |
| <p>Aboriginal participation and Project-related opportunities</p> <ul style="list-style-type: none"> • Potential employment, training, contracting and economic development opportunities • Community preparedness • Cultural recognition and naming • Revenue from tolling | <p>The Ministry is committed to working with Hwlitsum to identify potential employment, training, contracting and economic development opportunities and to identify ways to support community preparedness.</p> <p>The Ministry is exploring opportunities for cultural recognition and naming and will work with Hwlitsum on these opportunities.</p> <p>Revenue from tolling is only used to defray the costs of designing, constructing, operating and maintaining highways. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application.</p> |
| <p>Environmental Assessment (EA):</p> <ul style="list-style-type: none"> • Hwlitsum’s assignment on Schedule B as a sub-group of Penelakut • Adequacy of methodology to address social and cultural effects • Process and associated timelines • CEAA review | <p>The Ministry acknowledges the importance of Hwlitsum’s involvement in the environmental assessment process.</p> <p>Hwlitsum’s concerns related to Environmental Assessment including the their assignment on Schedule B, adequacy of methodology to address social and cultural effects, and process and associated timeline are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> <p>The Ministry reviewed the need for a federal review with the federal government. The Project does not meet the Canadian Environmental Assessment Agency (CEAA) requirements for a federal review. Federal agencies, including Environment and Climate Change Canada, are members of the Technical Working Group</p> |

| Concerns Identified to Date | Response |
|---|--|
| <p>Effects to fish and fish habitat</p> <ul style="list-style-type: none"> • Importance of fish and fish habitat including species of cultural and economic importance such as eulachon, sturgeon and salmon • Potential effects of pile driving, blasting and underwater noise generated by Tunnel decommissioning and other construction activities | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon, salmon to Hwlitsum and is committed to avoiding or mitigating any potential effects.</p> <p>The Ministry designed a clear span bridge over the Fraser River South Arm and Deas Slough to avoid or minimize Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Hwlitsum’s Fisheries Department continues to be very helpful in the review of Green Slough concepts.</p> <p>As outlined in Section 4.3 (Underwater Noise), sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources will be effectively mitigated by scheduling activities during period of low tide, when work can be completed under shallow water conditions or in the dry.</p> |
| <p>Social effects of the Project on Hwlitsum’s ability to transfer knowledge, language and participate in socio-cultural practices</p> | <p>Social effects of the Project on Hwlitsum’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C of the Application. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3 and Section 10.3 of Part C of the Application.</p> |

| Concerns Identified to Date | Response |
|---|---|
| <p>Potential effects of construction during fishing season on fishing activities. Effects of construction and decommissioning-related barging activities on Hwlitsum fishing.</p> | <p>Hwlitsum’s access to the Fraser River and the potential to displace fishing vessels (access to river locations for traditional use as a result of changes to physical characteristics of these locations) is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined. A negligible direct effect on access to instream locations for traditional use and a negligible effect to upland locations for traditional use has been determined. Mitigation measures are outlined in Section 5.2.4 (Marine Use Mitigation Measures) of the Application.</p> |
| <p>Cumulative effects:</p> <ul style="list-style-type: none"> • Consideration of cumulative effects on Aboriginal rights • Absence of comprehensive study on cumulative effects on the Fraser River | <p>The Application includes historical context relating to changes in use over time by Hwlitsum and other Aboriginal Groups (i.e., cumulative effects on this use to date), where this information has been provided to the Ministry by Hwlitsum or was otherwise available from publicly available sources. However, there is no EAO requirement to assess incremental cumulative effects on the exercise of Aboriginal Interests separately of the cumulative effects assessments on VCs that are directly linked to the exercise of those Aboriginal Interests.</p> <p>While the Ministry acknowledges that Hwlitsum is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project.</p> |
| <p>Potential effects on Fraser River flow rates after Tunnel removal</p> | <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Flow rates are discussed in Section 4.1 (River Hydraulics).</p> |

| Concerns Identified to Date | Response |
|---|---|
| Potential effects of run off and drainage | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will ensure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected.</p> <p>Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> |

3.0 Community Profile – Hwlitsum

Members of the Hwlitsum community, who consider themselves descendants of the Lamalchi and close relatives of the Penelakut Tribe (i.e., from Kuper Island), reside in the area of Canoe Pass, and carry the Halkomelem name for this location (e.g., *Hwlhitsu'm*, *Xwulit'sum*). While Hwlitsum community members, who number over 300, are individually registered Indians under the *Indian Act*, they are not collectively recognized as a “band” under the *Indian Act* and do not have any reserves. The group is represented by a chief.

Hwlitsum report that early ethnographic sources often employ the term “Cowichan” to refer to a set of linked communities that include the Hwlitsum. Hwlitsum consider the “Island” dialect of Halkomelem as their ancestral language and have described themselves as related to but independent of the Cowichan Nation community.

In 2008, Hwlitsum’s Statement of Intent was accepted into the British Columbia Treaty Commission process. The Ministry understands that Canada and BC advised Hwlitsum at that time that they had decided to not continue negotiations to Stage 2 of that process.

3.1 Hwlitsum Aboriginal Interests: Existing Conditions

This section provides a high level of summary of past, present, and desired future use of the proposed Project area and surroundings for traditional purposes are or may be connected with the exercise of Hwlitsum’s Aboriginal Interests. A more detailed discussion, including sources used, is provided under Hwlitsum in **Section 10.1.3.2 Existing Conditions**.

3.1.1 General

- The Project is located within Hwlitsum territory, upstream of Hwlitsum’s current and traditional year-round residence at Canoe Pass and downstream of *Tl'uqtinus*, along the Fraser River in the vicinity of the north end of the George Massey Tunnel.
- Hwlitsum report that *Tl'uqtinus* was a home base occupied and used exclusively by the Cowichan Nation, of which the Hwlitsum consider themselves to be descendants. Hwlitsum have stressed, however, that they are independent of the Cowichan Nation community and consult on their own behalf.

3.1.2 Fishing

- Hwlitsum followed a seasonal round of resource use and regional settlement that involved spending summers on the Lower Mainland (March to November). Hwlitsum began living year-round at Canoe Pass, reported as the centre of Hwlitsum fishing, after 1863.
- While part of their salmon fishing season was also spent at *Tl'uqtinus*, all species of salmon, cutthroat, Dolly Varden, dogfish, flounder, steelhead, smelt oysters, crab, sturgeon, eulachon, and trout are or have been obtained by Hwlitsum at Canoe Pass or at nearby locations.
- Salmon, steelhead, trout, and sturgeon were also taken further up the Fraser River and its tributaries.
- Areas within the wider Fraser River estuary were also reportedly utilized by Hwlitsum for fishing salmon, sturgeon, groundfish, and other marine resources.
- Hwlitsum harvest crab and bivalve species such as clams, cockles, mussels, oysters, and abalone in the Gulf Islands.
- Shrimp are generally harvested throughout the Strait of Georgia (between the Gulf Islands and the Lower Mainland), as well as immediately west of the existing Roberts Bank terminals, with targeted shrimp harvesting at Sturgeon Bank.
- Other marine invertebrates taken include red and green sea urchin, octopus, squid and sea cucumber, all harvested on the western side of the Strait of Georgia

3.1.3 Hunting/Trapping

- Hwlitsum have hunted at “Canoe Pass and all along the Fraser River as far up as Hope and Yale”.
- Species harvested by Hwlitsum in the vicinity of the South Arm of the Fraser River have included seal, otter, muskrat (Westham Island), black duck, mallard, widgeon, geese (snow, Canada), brant, pintail, pigeon, pheasant (Ladner Reach), and red fox; at Burns Bog, deer, and black bear have been taken.
- Many of these species continue to be harvested by Hwlitsum members.

3.1.4 Gathering

- Hwlitsum have said they gathered up to 20 plant species from areas throughout their traditional round for food, medicinal, and other purposes.
- Plants said to be currently utilized in the area of Canoe Pass include cattails, rhubarb, crab apple, and plums. Ferns and alder (for firewood and smoking salmon) have been reported as collected at Burns Bog, with cottonwood having been gathered in the area of *Tl'uqtinus*. Hwlitsum also report harvesting marine plants, such as kelp, seaweed, and rockweed, from the Gulf Islands.

3.1.5 Archaeology and Cultural Heritage Interests

- No information on Hwlitsum’s interests with respect to archaeology were identified in the study prepared for this Project, *Hwlitsum Traditional Use and Occupancy Study 2015*, or in publicly available sources.
- Hwlitsum report that changes in resources and their use have disrupted community life and gatherings and that without fishing, hunting, and gathering, they will be unable to continue to pass on the teachings of generations of their ancestors.

3.1.6 Other Related Interests

- Hwlitsum have said that accessibility and availability of healthy local species for harvest within their traditional territory is important for food security as well as ritual and spiritual practices.

4.0 Potential Effects

This section provides a summary of the methodology used to identify potential adverse effects of the proposed Project on the exercise of Aboriginal Interests by Aboriginal Groups during Project construction and operation, followed by a summary of potential effects on Hwlitsum’s Aboriginal Interests, specifically. For a more detailed description of the methodology and a summary of the results, refer to **Section 10.1.3.3. Potential Effects**.

4.1 Methodology for Identification of Potential Effects

The first step in the effects assessment on Aboriginal interests was the identification of potential adverse effects on traditional use activities and related interests as a result of Project construction or operation. To evaluate these potential adverse effects, the findings of the following Valued Component (VC) chapters in Part B of the Application were considered, including identified mitigation measures, residual effects, cumulative effects and follow up strategies:

- **Section 4.4 Fish and Fish Habitat**
- **Section 4.6 Marine Mammals**
- **Section 4.7 Vegetation**
- **Section 4.8 Terrestrial Wildlife**
- **Section 5.2 Marine Use**
- **Section 5.3 Land Use**
- **Section 5.5 Visual Quality**
- **Section 6.1 Heritage Resources**
- **Section 7.1 Human Health**

The findings of the following Intermediate Component (IC) chapters were also considered in the assessment:

- **Section 4.1 River Hydraulics and River Morphology**
- **Section 4.2 Sediment and Water Quality**
- **Section 4.9 Air Quality**
- **Section 4.10 Atmospheric Noise**

The assessment of potential adverse effects of the Project on the exercise of Aboriginal Interests, including measures to address those effects, are presented in **Section 10.1.3.3** through **Section 10.1.3.5**, and largely applies the same methods used in Part B of the Application for the IC and VC assessments, as outlined in **Section 3.0 Assessment Methodology**.

In addition to information from the VC and IC assessments that support the assessment of potential effects on Aboriginal Interests, information from a Health Impact Assessment (HIA) undertaken to support Project planning, including mitigation recommendations, has been integrated into the assessment of potential effects on Aboriginal Interests. The HIA for the Project can be found at <https://engage.gov.bc.ca/masseytunnel>. A summary of the key findings is provided in **Section 7.2 Health Impact Assessment**.

4.2 Selection of Indicators

Four parameters were chosen as indicators to understand and evaluate potential Project-related effects on the exercise of Aboriginal Interests. The rationale for their selection is presented in the following table.

Table 2 Indicators for the Aboriginal Interests Assessment

| Indicator | Rationale for Selection |
|---|---|
| Access to preferred locations for the exercise of Aboriginal Interests | Project components or activities could result in changes in access to or patterns of travel between traditional use locations on land or water |
| Availability of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in distribution or movement, relative abundance, or habitat area or composition of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of preferred resources for the exercise of Aboriginal Interests | Project components or activities could result in changes in the real or perceived quality of traditional use resources (as informed by IC or VC assessments pertaining to these resources) in traditional use areas (as informed by information provided by Aboriginal Groups or available in public sources specific to the exercise of their Aboriginal Interests) |
| Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests | Project components or activities could result in: (1) direct sensory disturbance to traditional users (e.g., from noise, vibration); and/or (2) indirect changes to cultural practices, customs or traditions – i.e., cultural heritage or the expression and transfer of cultural values or ways of knowing (e.g., language, laws/governance, stories, spiritual beliefs) – tied to the cultural landscape or to the traditional use of specific traditional use locations or resources within that landscape. |

Potential adverse effects on the indicators noted above were analyzed in terms of the type and level of effect that Project components and activities may be expected to have on the exercise of Aboriginal Interests.

For the purposes of this assessment, no effect was understood to mean that no interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests would be expected. Where it was determined that an interaction, and potential effect, could occur, the following definitions were used to guide the characterization of the effect as negligible or measurable:

- Negligible – An interaction between Project components or activities and preferred locations or preferred resources for the exercise of Aboriginal Interests may occur, but modifications to the use of preferred options would not be expected.
- Measurable – Modifications to the exercise of Aboriginal Interests at preferred locations or in relation to preferred resources may be needed, and may be considered to be:
 - Minor (minimal or temporary modifications may be required to use preferred options),
 - Moderate (more frequent or longer term modifications may be required to use preferred options), or
 - Serious (permanent or indefinite modifications may be required potentially resulting in the loss of preferred options).

4.3 Identified Potential Effects

As noted above, the first step in evaluating potential adverse effects on Aboriginal Interests was a consideration of the findings for relevant Part B VCs and ICs, including identified mitigation measures, residual effects, cumulative effects and follow up strategies. The residual effects with the potential to result in an adverse effect on Aboriginal Interests are then carried forward in the assessment. Using the four indicators noted in the previous section, the potential Project-related effects and level of effect predicted in relation to Hwlitsum's exercise of Aboriginal Interests remaining after Part B mitigation are as follows:

Table 3 Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests

| | Construction | | Operation | | Residual Potential Effects |
|---|--------------|------------|------------|------------|----------------------------|
| | Negligible | Measurable | Negligible | Measurable | |
| River locations for traditional use as a result of changes to physical characteristics of these locations | ✓ | | ✓ | | |
| Instream locations for traditional use | ✓ | | ✓ | | |
| Upland locations for traditional use | ✓ | | ✓ | | |

4.4 Potential Project-Related Effects Hwlitsum’s Aboriginal Interests

Using the methodology presented in **Section 10.1.3.3 Potential Effects**, Table 7 provides the potential incremental Project-related effects, following mitigation of Project-related effects on Part B VCs and ICs as described in Part B, related to Hwlitsum’s Aboriginal Interests as summarized in Existing Conditions were identified for construction and operation. A discussion of potential Project-related effects on fishing, hunting/trapping, gathering and archaeology and cultural heritage follows the table.

Table 7 Summary of Potential Project-Related Effects

| Indicator | Potential Project-Related Effect | Potentially-Affected Aboriginal Interests |
|--|---|--|
| Project Construction | | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |
| Changes in Quality of Experience in Exercising, or tied to the Exercise, of Aboriginal Interests | <ul style="list-style-type: none"> • Potential temporary direct (minor) effect on quality of experience related to construction-related noise • Potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance | <ul style="list-style-type: none"> • Fishing • Hunting/Trapping • Gathering • Archaeology & Cultural Heritage • Other Related Interests |

| Indicator | Potential Project-Related Effect | Potentially-Affected Aboriginal Interests |
|--|---|--|
| Project Operation | | |
| Changes in Access to Preferred Locations for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |
| Changes in Availability of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |
| Changes in Quality of Preferred Resources for the Exercise of Aboriginal Interests | <ul style="list-style-type: none"> • None identified | <ul style="list-style-type: none"> • n/a |

4.5 Fishing

Hwlitsum harvest crab and bivalve species such as clams, cockles, mussels, oysters, and abalone in the Gulf Islands. Shrimp are generally harvested throughout the Strait of Georgia (between the Gulf Islands and the Lower Mainland), as well as immediately west of the existing Roberts Bank terminals, with targeted shrimp harvesting at Sturgeon Bank. Other marine invertebrates taken include red and green sea urchin, octopus, squid and sea cucumber, all harvested on the western side of the Strait of Georgia

The proposed Project has the potential to affect fishing practices through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred fishing locations by Hwlitsum, as a result of changes in river hydraulics or morphology, are expected to be negligible before mitigation. Potential changes in access to instream locations for fishing by Hwlitsum during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to fishing locations by Hwlitsum from instream construction activities are expected to be negligible. While it is acknowledged that Hwlitsum has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Mitigation measures identified in the fish and fish habitat assessment to address Project-related effects on fish are expected to be effective at addressing potential effects on the availability of fishing resources preferred by Hwlitsum. Further, as residual effects on fish identified in the fish and fish habitat assessment are not anticipated to affect population integrity, potential residual effects as a result of Project construction activities, would not be expected to measurably affect the availability of preferred fish resources.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of fishing resources preferred by Hwlitsum; therefore, Potential Project-related effects on Hwlitsum fishing would be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when fishing are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** are expected to largely address a potential Project-related effect to the quality of experience while fishing. At preferred fishing locations that overlap or are in proximity to known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Hwlitsum.

Section 5.5 Visual Quality predicts that residual effects to visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Hwlitsum is fishing. As this landscape has been previously modified, the potential Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Hwlitsum's Aboriginal Interests related to fishing are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.6 Hunting/Trapping

Hwlitsum have hunted at "Canoe Pass and all along the Fraser River as far up as Hope and Yale". Species harvested by Hwlitsum in the vicinity of the South Arm of the Fraser River have included seal, otter, muskrat (Westham Island), black duck, mallard, widgeon, geese (snow, Canada), brant, pintail, pigeon, pheasant (Ladner Reach), and red fox; at Burns Bog, deer, and black bear have been taken. Many of these species continue to be harvested by Hwlitsum members.

The proposed Project has the potential to affect hunting and trapping through changes in access to preferred locations, changes in availability of preferred locations, changes in quality of preferred resources and changes in quality of experience when fishing.

Potential changes in access to preferred hunting and trapping locations by Hwlitsum as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for hunting and trapping by Hwlitsum during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to hunting and trapping locations by Hwlitsum from instream construction activities, are expected to negligible. While it is acknowledged that Hwlitsum has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for hunting and trapping by Hwlitsum resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with hunting and trapping locations.

Mitigation measures identified in the marine mammal and terrestrial wildlife assessments are expected to be effective at addressing potential effects on the availability of hunting and trapping resources preferred by Hwlitsum. Therefore, Project-related effects on hunting and trapping related to potential changes in the availability of resources would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for hunting and trapping by Hwlitsum; therefore, Potential Project-related effects on Hwlitsum fishing would be expected to be negligible.

Project operation is not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when hunting and trapping are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** to address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while hunting and trapping. At preferred hunting and trapping locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Hwlitsum.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Hwlitsum is hunting and trapping. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Hwlitsum's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.7 Gathering

Hwlitsum have reported that they gathered up to 20 plant species from areas throughout their traditional round for food, medicinal, and other purposes. Plants said to be currently utilized in the area of Canoe Pass include cattails, rhubarb, crab apple, and plums. Ferns and alder (for

firewood and smoking salmon) have been reported as collected at Burns Bog, with cottonwood having been gathered in the area of *Tl'uqtinus*. Hwlitsum also report harvesting marine plants, such as kelp, seaweed, and rockweed, from the Gulf Islands.

The proposed Project has the potential to affect gathering through changes in access to preferred locations, changes in availability of preferred resources, changes in quality of preferred resources and changes in quality of experience when gathering.

Potential changes in access to preferred gathering locations by Hwlitsum as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations for gathering by Hwlitsum during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to gathering locations by Hwlitsum from instream construction activities, are expected to be negligible. While it is acknowledged that Hwlitsum has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations for gathering by Hwlitsum resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and is not expected to overlap with gathering locations.

Mitigation measures identified in the vegetation assessment to address Project-related effects on terrestrial vegetation are expected to be effective at addressing potential effects on the availability of resources for the exercise of Aboriginal Interests related to gathering. Therefore, Project-related effects on gathering related to potential changes in the availability of vegetation would be expected to be negligible after the implementation of mitigation identified in Part B of the Application.

Mitigation measures identified in the assessments in **Section 4.2 Sediment and Water Quality** and **Section 4.9 Air Quality** are expected to be effective at addressing potential effects on the quality of preferred resources for gathering by Hwlitsum; therefore, Potential Project-related effects on gathering related to potential changes in the quality of resources would therefore be expected to be negligible.

Project operation activities are not expected to lead to perceptible changes in ground-borne vibration levels or result in residual adverse changes in air quality; therefore, Project-related air quality or vibration effects on the quality of experience when gathering are either not expected or would be expected to be negligible.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** address changes in noise levels during construction and operation, would also be expected to address the potential Project-related effect to the quality of experience while gathering. At preferred gathering locations that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Hwlitsum.

Section 5.5 Visual Quality predicts that residual effects on visual quality may be experienced only within 1 km of the new bridge; however, the addition of a new feature to this landscape may affect the quality of experience when Hwlitsum is gathering. As this landscape has been previously modified, potential Project-related effects on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal.

Additional mitigation to address potential incremental Project-related effects on Hwlitsum's Aboriginal Interests related to gathering are proposed in **Section 10.1.3.4** and summarized below under Mitigation.

4.8 Archaeology and Cultural Heritage Interests

The proposed Project has the potential to affect Hwlitsum's Aboriginal Interests related to archaeology and cultural heritage through changes in access to preferred locations and changes in quality of experience.

Potential changes in access to locations related to Hwlitsum's archaeological and cultural heritage interests as a result of changes in river hydraulics or morphology are expected to be negligible before mitigation. Potential changes in access to instream locations related to Hwlitsum's interests related to archaeology and cultural heritage during Project operation are also expected to be negligible as the bridge is designed to be clear span.

Potential changes in access to locations related to Hwlitsum's archaeological and cultural heritage interests from instream construction activities are expected to be negligible. While it is acknowledged that Hwlitsum has reported a desire for higher levels of use in this portion of the river based on historic use, the episodic and short-term access effects that are anticipated as a result of instream Project-related construction activities are not expected to measurably affect their current or desired future use.

Potential changes in access to upland locations related to Hwlitsum’s archaeological and cultural heritage interests resulting from Project footprint effects during operation are expected to be negligible, as the majority of lands required for physical works is within the existing Highway 99 right of way and not expected to overlap with locations related to Hwlitsum’s archaeological and cultural heritage interests.

With regard to noise, mitigation measures proposed in **Section 4.10 Atmospheric Noise** would also be expected to address the potential Project-related effect to the quality of experience while undertaking activities related to cultural heritage. At locations related to Hwlitsum’s archaeological and cultural heritage interests that overlap, or are in proximity to, known noise-sensitive locations for which Project operation-related effects may not be fully mitigable or reversible, changes in noise levels as a result of Project operation could have an effect on the quality of experience at those locations for Hwlitsum.

As reported in **Section 6.1 Heritage Resources**, no archaeological or historical sites were identified within the Project area during fieldwork; however, there may be other locations with intangible cultural value or meaning to Hwlitsum (e.g., spiritual or storied sites, named places) potentially affected by the Project. In addition, physical alterations to the landscape may affect archaeological or historical sites, and how this landscape is experienced culturally.

As a result, mitigation measures proposed in Part B are not expected to address a potential incremental and permanent Project-related effect tied to Hwlitsum’s Aboriginal Interests related to archaeology and cultural heritage that may be associated with the introduction of a new prominent feature to the cultural landscape. As this landscape has been previously modified by anthropogenic changes, the potential incremental Project-related effect on the quality of experience tied to the exercise of Aboriginal Interests is expected to be minimal, but permanently disruptive for Hwlitsum, who have identified a historical connection to, and continued or desired use of, sites or places that help define the cultural landscape in the Project area.

Additional mitigation to address this potential incremental effect that is not otherwise addressed in the Application is proposed in **Section 10.1.3.4** and summarized below under Mitigation.

5.0 Mitigation

This section provides a summary of mitigation measures identified to address potential Project-related effects on the exercise of Aboriginal Interests by Hwlitsum. For a more detailed discussion, refer to **Section 10.1.3.4 Mitigation**.

Mitigation measures identified for the relevant VCs and ICs in Part B of the Application were reviewed to assess their effectiveness at addressing potential Project-related effects on the exercise of Aboriginal Interests related to those VCs. Examples of mitigation that are proposed in the Application to address potential effects on VCs and ICs, with the potential to result in an effect on Aboriginal Interests, include:

- Avoiding fisheries sensitive timing windows during key Project activities.
- Developing a Marine Access Management Plan to ensure marine use activities, including those supporting Aboriginal Interests, can continue during Project construction.
- Scheduling activities with the potential to generate underwater noise to avoid potential effects on marine mammals.
- Development and implementation of a Terrestrial Vegetation and Wildlife Management Plan with measures to minimize disturbance and loss of vegetation, prevent soil compaction, and minimize clearing in order to minimize effects on vegetation.

These measures are expected to be largely effective at avoiding, reducing, or otherwise managing potential Project-related effects on the exercise of Aboriginal Interests during Project construction and operation.

Recognizing some measurable effects on Hwlitsum's Aboriginal Interests could remain following the application of mitigation to address potential effects on the relevant VCs and ICs in Part B, the following additional measures have been identified to address such effects:

- Ongoing consultation with Hwlitsum regarding proposed measures, management plans, and monitoring programs related to intermediate components and valued components assessments; and
- Development of a Cultural Heritage Management Plan.

6.0 Residual Effects

With the implementation of mitigation measures identified in **Section 10.1.3.4** and summarized above, residual adverse effects of the proposed Project on the exercise of Aboriginal Interests are expected to be negligible (i.e., not measurable or detectable), and are not further assessed.

7.0 Summary and Conclusion

Part C of the Application builds on consultation undertaken to date to understand Hwlitsum's Aboriginal Interests and provides for an assessment of potential Project-related effects of the Project on Aboriginal Interests.

The Ministry began consultations with Hwlitsum prior to the submission of the Project Description, which is the end of the Initial Consultation Phase. Both EAO and the Ministry consulted with Hwlitsum during the Pre-Application Phase, which concluded with the submission of the Application. The main concerns expressed by Hwlitsum during consultations include:

- Adequacy of Environmental Assessment (EA) methodology to address social and cultural effects;
- Federal government participation in regulatory process and participation of federal government in Working Group;
- Hwlitsum's assignment on Schedule B as a sub-group of Penelakut;
- Potential impacts to Hwlitsum's Aboriginal Interests, including fishing, hunting and gathering;
- Cumulative effects;
- Effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon;
- Capacity funding for Traditional Use Study and to facilitate participation in the Project review process;
- Aboriginal participation and Project-related opportunities;
- Cumulative effects on Aboriginal Interests;
- Protection of archaeological and heritage resources and opportunities for cultural recognition and naming;
- Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations;
- Change in flow rates after Tunnel removal;
- Potential effects of the bridge structure, lighting, and noise on terrestrial wildlife, marine mammals, waterfowl, and migratory birds;
- Inclusion of culturally significant plants in planting plans and opportunity for Lyackson in the identification of plants, and planting work. Need for management of invasive plant species; and
- Potential effects of run off and drainage along the highway corridor, including heavy metal transport from traffic to water and land, management of runoff from the bridge.

Based on information provided by Hwlitsum and other publicly-available sources, the Ministry developed a summary of past, present and desired future use of the proposed Project area and its surroundings for the purposes of fishing, hunting/trapping, gathering, archaeology and cultural heritage interests and other related interests. This summary indicates that Hwlitsum has, does and intends to continue to use the Fraser River for cultural purposes.

Relying first on the results of the effects assessments for related VCs and ICs in Part B, the assessment of potential effects of Hwlitsum's Aboriginal Interests considered four indicators:

1. Access to preferred locations for the exercise of Aboriginal Interests;
2. Availability of preferred resources for the exercise of Aboriginal Interests;
3. Quality of preferred resources for the exercise of Aboriginal Interests; and
4. Quality of experience in exercising, or tied to the exercise of, Aboriginal Interests.

As reviewed in **Section 10.1.3.3** and **Section 10.1.3.4**, the mitigation measures, management plans, and monitoring programs identified in Part B of the Application for ICs or VCs linked to the exercise of Aboriginal Interests are expected to be largely effective at addressing the incremental Project-related effects noted above on the exercise of Aboriginal Interests by Hwlitsum, except in the following potentially measurable cases:

- Project construction:
 - Potential temporary direct (minor) effect on quality of experience related to construction-related noise and a potential temporary indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance
- Project operation:
 - Potential permanent direct (minor) effect on quality of experience related to traffic noise and a potential indirect (minor) effect on quality of experience (i.e., cultural heritage) tied to traditional uses that may be avoided due to direct sensory disturbance while engaged in those uses
 - Potential permanent indirect (moderate) effect on quality of experience (i.e., cultural heritage) tied to traditional uses due to visual disturbance to the cultural landscape that informs and supports those uses.

The following additional measures have been identified to address the above-noted effects:

- Ongoing consultation with Hwlitsum regarding proposed measures, management plans, and monitoring programs related to IC and VC assessments; and
- Development of a Cultural Heritage Management Plan.

With the implementation of mitigation proposed to address potential effects on VCs and ICs, as well as additional mitigation proposed to address potential residual effects on Aboriginal Interests, no effects on the exercise of Aboriginal Interests by Hwlitsum, as a result of the Project, are expected.

ENVIRONMENTAL ASSESSMENT PROCESS

An environmental assessment of the Project is required under the B.C. *Environmental Assessment Act* (B.C. *EAA*), S.B.C. 2002, c. 43, and permits to construct and operate can only be received once the environmental assessment process is complete and an Environmental Assessment Certificate (EAC) has been issued. If the Project is approved, an EAC will be awarded to and held by the Ministry. The Reviewable Projects Regulation B.C. Reg. 370/2002 under the B.C. *EAA* sets out the criteria for reviewable projects.

On December 16, 2015, the B.C. Environmental Assessment Office (EAO) issued a Section 10(1)(c) Order confirming that the Project is a reviewable project pursuant to the B.C. *EAA*, and that it requires an EAC.

The Project as proposed is not subject to review under the *Canadian Environmental Assessment Act, 2012*, S.C. 2012, c. 19, s. 52, since it does not meet the definition of a physical activity under the Schedule of Physical Activities in the Regulations Designating Physical Activities SOR/2012-147.

EAO is a neutral agency that manages the review of proposed major projects in British Columbia, as required by the *Environmental Assessment Act*.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------------|-------------------------|
| Social and cultural effects and the adequacy of Environment Assessment (EA) methodology. | <p>Concerns related to the adequacy of Environmental Assessment are outside the scope of the Project and have been referred to the Environmental Assessment Office (EAO).</p> <p>Social and cultural effects of the project are considered in Part C of the Environmental Assessment Application (Application). Where Aboriginal Groups values and perspectives have been provided to the Proponent regarding environmental, economic, social, heritage or health valued components (VCs), they have been incorporated, where applicable into the Part B assessment of those VCs.</p> | Referred to EAO | None |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|--------------------------|-------------------------|
| Strength of Claim assessment and related depth of consultation. | Concerns related to the strength of claim assessment have been referred to EAO and MARR. | Referred to EAO and MARR | None |
| Federal government participation in regulatory process and participation of federal government in Working Group. | Ministry reviewed the need for a federal review with the federal government. The Project did not meet the Canadian Environmental Assessment Agency (CEAA) requirements for a federal review. Federal agencies, including Environment and Climate Change Canada, are members of the Technical Working Group. | Addressed | None |
| Hwlitsum’s assignment on Schedule B as a sub-group of Penelakut | Concerns related to Hwlitsum’s assignment on Schedule B have been referred to the Environmental Assessment Office (EAO). | Referred to EAO | None |
| Request to be referred to as Hwlitsum First Nation | Hwlitsum’s request to be referred to as Hwlitsum First Nation is acknowledged; however, the name is reproduced verbatim from the Section 11 Order. Hwlitsum’s point that they have been recognized as a First Nation by government entities, including the BC Treaty Commission, has been added to Aboriginal Consultation Report #2 and to this Issues Summary Table. | Addressed | None |

ABORIGINAL INTERESTS

There are potential Project related impacts to Hwlitsum’s title, Rights and culture. Potential effects and the level of effect predicted include:

1. Access to preferred locations for the exercise of Aboriginal Interests (access to river locations for traditional use as a result of changes to physical characteristics of these locations).
2. Availability of preferred resources for the exercise of Aboriginal Interests (availability of fish, marine mammal, vegetation and terrestrial wildlife resources for Traditional Use).
3. Quality of preferred resources for the exercise of Aboriginal Interests (quality of water used for cultural purposes, quality of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use).
4. Quality of experience of exercising, or tied to the exercise, of Aboriginal Interests (quality of experience tied to the traditional use of river locations as a result of changes to the physical characteristics of the location; quality of experience tied to access of instream and upland areas locations for traditional use; quality of experience tied to use of water for traditional purposes; quality of experience tied to the traditional use of fish, marine mammal, vegetation and terrestrial wildlife resources for traditional use; and quality of experience while engaged in or tied to traditional use as a result of changes in air quality, noise, ground-borne vibration and to the cultural landscape).

Measureable Effects

Access for traditional use

- Cultural landscape

Quality of experience while engaged in or tied to traditional use

- cultural landscape

No, Negligible or Moderate Effects

Quality of experience while engaged in or tied to traditional use

- Noise

Negligible Effects

Access for traditional use

- Instream locations
- River locations
- Upland locations

ABORIGINAL INTERESTS

Quality for Traditional Use

- Water
- Fish resources
- Marine mammal resources
- Vegetation resources

Quality of experience while engaged in or tied to traditional use

- Fish resources
- Instream locations
- Marine mammal resources
- River locations
- Terrestrial wildlife resources
- Upland locations
- Water
- Vegetation resources

Availability for Traditional Use

- fish resources
- Marine mammal resources
- Terrestrial wildlife resources
- Vegetation resources

No to Negligible Effects

Quality of experience while engaged in or tied to traditional use

- changes to the cultural landscape

No or Negligible Effects

Quality of experience while engaged in or tied to traditional use

- Air quality
- Ground-borne vibration

ABORIGINAL INTERESTS

High, Short-term Probability of Effect

- Disturbance to residential, commercial and industrial land uses
- Disturbance to recreational uses near the new bridge

Moderate, Long-term Probability of Effect

- Disturbance to visual quality

Low, Short-term Probability of Effect

- Barn swallow habitat loss (construction period)
- Physical injury or mortality to fish through crushing or entrainment (construction period)

Low, Long-term Probability of Effect

- Barn owl mortality

No Significant Residual or Cumulative Effects

- Air quality
- Fish and fish habitat
- Heritage resources
- Marine access
- Marine mammals
- River hydraulics and river morphology
- Sediment and water quality
- Terrestrial Wildlife
- Vegetation

The Ministry has developed mitigation measures to address these Potential effects. Residual effects on the exercise of Aboriginal Interests by Hwlitsum as a result of the Project are not expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|---------------------------------|--|
| <p>Hwlitsum “is greatly concerned that the Project will negatively impact our ability to fish, hunt and gather as we have done since time immemorial. These practices are central and integral to our Hwlitsum and Coast Salish identity and without them, we are unable to continue to pass on the teachings of generations of our ancestors.”</p> | <p>Hwlitsum’s ability to harvest within the Project area are addressed in Part C of the Application.</p> <p>With the implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife, residual effects on the exercise of Aboriginal Interests by Hwlitsum as a result of the Project are not expected.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in all Sections 4.4.4 (Fish and Fish Habitat Mitigation Measures), 4.6.4 (Marine Mammals Mitigation Measures), 4.7.4 (Vegetation Mitigation Measures), and 4.8.4 (Terrestrial Wildlife Mitigation Measures)</p> |
| <p>Hwlitsum’s access to the Fraser River and the potential to displace fishing vessels.</p> <p>Potential interference with Aboriginal fisheries during decommissioning of the Tunnel and the importance of working closely with communities to ensure negative effects are avoided.</p> | <p>Hwlitsum’s access to the Fraser River and the potential to displace fishing vessels (access to river locations for traditional use as a result of changes to physical characteristics of these locations) is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined. A negligible effect on access to instream locations for traditional use and a negligible effect to upland locations for traditional use has been determined.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation measures outlined in Section 5.2.4 (Marine Use Mitigation Measures)</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|--|
| <p>Social effects of the Project on knowledge transmission, language loss, dependency and social interaction.</p> | <p>Social effects of the Project on Hwlitsum’s ability to transfer knowledge, language and participate in socio-cultural practices are discussed in Part C. Specifically, potential effects on cultural heritage (such as the ability to transfer knowledge, language, and participate in socio-cultural practices that support the maintenance of this heritage within and between generations) are considered through both direct and indirect effect pathways on the exercise of Aboriginal Interests as a result of Project components or activities. This analysis, which was dependent on cultural heritage information provided by Aboriginal groups or otherwise available through public sources, occurs predominantly within Section 10.1.3.3 Potential Effects of Part C of the Application, with results also provided on a nation-by-nation basis in Section 10.1.3.8 and Section 10.3 of Part C of the Application.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in all Sections of the Application</p> |
| <p>Protection of Hwlitsum’s rights to harvest within the Project area. Importance of ensuring fish and fish habitat is protected for future generations of Hwlitsum.</p> | <p>Hwlitsum’s rights to harvest within the Project area are addressed in Part C of the Application. With the implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife, residual effects on the exercise of Aboriginal Interests by Hwlitsum as a result of the Project are not expected.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures in Sections 4.4 (Fish and Fish Habitat), 4.6 (Marine Mammals), 4.7 (Vegetation), and 4.8 (Terrestrial Wildlife)</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|------------------|-------------------------|
| <p>Consideration of cumulative effects on aboriginal rights, including measurement against a pre-industrial baseline.</p> | <p>The Ministry’s cumulative effects assessment looked at potential incremental environmental effects of construction and operation of the Project in conjunction with other present and reasonably foreseeable projects that could interact with the potential effects of this Project. The process and methodology used to conduct the cumulative effects assessment, including the identification of potential cumulative effects, identification of additional mitigation measures, and evaluation of any (residual) cumulative effects is outlined in Part B of the Application. Other Projects that are considered in the assessment of Project-related cumulative effects are also listed.</p> | <p>Addressed</p> | <p>None</p> |
| <p>Absence of a comprehensive study of cumulative effects on the Fraser River.</p> | <p>While the Ministry acknowledges that Hwlitsum is interested in a comprehensive study of cumulative effects on the Fraser River, this is outside the scope of the Project.</p> | <p>Addressed</p> | <p>None</p> |

ABORIGINAL CONSULTATION

Aboriginal Interests, defined as asserted or determined Aboriginal rights, including title, and treaty rights, are known to overlap or lie in the vicinity of the Project corridor. Potential adverse effects on the exercise of Aboriginal Interests as a result of Project construction and operation have been identified.

Mitigation measures to address potential Project-related effects on intermediate components (ICs) and valued components (VCs) associated with the exercise of Aboriginal Interests are expected to be effective. With the application of mitigation, potential effects on the exercise of Aboriginal Interests are predicted to be negligible except in specific cases during Project construction and operation. To address potential effects during Project construction and operation, the development of an Archaeological and Heritage Resources Management Plan is proposed.

In addition to mitigation measures proposed to address potential effects on ICs and VCs, ongoing engagement between the Ministry and Schedule B Aboriginal Groups will be undertaken. Such engagement will take place during Application Review and, if the Project is approved, following the issuance of an Environmental Assessment Certificate (EAC). Engagement will involve consultation on management plans and monitoring programs, related to the exercise of Aboriginal Interests.

Ongoing engagement is also proposed to address other matters of environmental, economic, social, heritage, and health concern raised by Aboriginal Groups during the pre-Application period. With this ongoing engagement, residual effects on the exercise of Aboriginal Interests or other matters of concern as a result of the Project are not expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|-----------|---|
| Capacity funding to facilitate participation in the Project review process. | Hwlitsum received funding for the Pre-Application Phase. The Ministry will provide further funding for the Application Review Phase. | Addressed | Consultation regarding funding for the Application Review Phase |
| Appropriate use of information shared by Hwlitsum as it relates to confidentiality and dissemination. | The Ministry understands and respects that certain information shared by Hwlitsum may be considered confidential. The Ministry is subject to the provisions of the <i>Freedom of Information and Protection of Privacy Act</i> . However, subject to the requirements of applicable laws, the Ministry will respect Hwlitsum requests to keep information confidential. | Addressed | Appropriate use of confidential information |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|-----------|-------------------------|
| Importance of having opportunities for the community to learn about the Project. | The Ministry met with the Hwlitsum community and will continue to work with Hwlitsum in accordance with the Aboriginal Consultation Plan. | Ongoing | Ongoing consultation |
| Traditional Use Study: <ul style="list-style-type: none"> • Funding for Traditional Use Study (TUS). • Amount of funding provided for TUS. | The Ministry signed a funding agreement with Hwlitsum which provided funding for a Traditional Use Study. | Addressed | None |

ABORIGINAL PARTICIPATION AND PROJECT-RELATED OPPORTUNITIES

The Ministry is actively exploring opportunities to provide benefits, economic and non-economic, to Aboriginal Groups that are directly affected by the Project. Opportunities include employment, training, and contracting as well as participation in environmental enhancement and other components of the Project.

Prior to the Pre-Application Phase of the Project, the Ministry worked with Schedule B Aboriginal Groups to determine appropriate tools to support consultation. Consultation activities were based on the specific needs and preferences of these Aboriginal Groups and the Consultation Plan included individualized plans that were co-developed and reviewed.

The Project's Aboriginal Consultation Plan has been developed in consultation with Schedule B Aboriginal Groups, in order to meet the Aboriginal consultation requirements as delegated by EAO and to maintain and, where possible, enhance positive working relationships between the Ministry and the respective Aboriginal Groups.

The objectives and requirements of the Aboriginal Consultation Plan are to:

- Provide relevant Project-related information in a timely and effective manner that supports an understanding of the nature of the Project and its potential adverse effects on Aboriginal Interests
- Plan and implement mutually acceptable consultation activities that support effective participation of Aboriginal communities in the EA as well as related regulatory and permitting processes
- Establish and maintain dialogue throughout the EA as a means of providing opportunities to respond to outstanding concerns
- Provide opportunities for Aboriginal Groups to share views of the Project with the Ministry and EAO within reasonable timeframes
- Provide opportunities for Aboriginal Groups to identify potential adverse effects of the proposed Project on Aboriginal Interests, including cumulative effects and, to the extent appropriate, develop ways to mitigate or otherwise accommodate potential adverse effects
- Involve Aboriginal Groups, where possible, in relevant studies including, but not limited to, archaeological fieldwork.
- Incorporate community and traditional knowledge in Project components

Document and report to EAO on the Ministry's Aboriginal consultation program at times specified by EAO.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|-----------|---|
| Opportunities for cultural recognition and naming. | The Ministry is exploring opportunities for cultural recognition and naming and will work with Hwlitsum on this matter. | Ongoing | Discussions with Hwlitsum to explore opportunities related to cultural recognition and naming, art and interpretive signage |
| Project-related employment, training, contracting, and economic development opportunities. | The Ministry is committed to working with Hwlitsum to identify potential opportunities to benefit from the Project. Ministry acknowledges that Aboriginal Groups want to prepare their membership for employment opportunities and will work with Hwlitsum to identify ways to support community preparedness. | Ongoing | The Ministry will share information as it becomes available to support community preparedness and welcomes input from Hwlitsum on the type of information that would be useful. |
| Revenue sharing opportunities from tolling. | Revenue from tolling is only used to defray the costs of designing, constructing, operating and maintaining highways. A discussion on tolls is included in Sections 1.0 and 5.1 of the Application. | Addressed | None |

4.1 RIVER HYDRAULICS

The proposed bridge will have a clear-span, which eliminates potential changes to river hydraulics or river morphology resulting from the new structure. The Fraser River South Arm is dynamic with scour in the order of several metres during freshet and migrating sand dunes with heights of up to four metres. Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor. Tunnel removal is expected to result in temporary bed lowering between the Tunnel and Lulu Island-Delta water main; however, no permanent effect on the Lulu Island-Delta watermain is expected.

Effects

A negligible effect to access to river locations for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of river locations has been determined.

Mitigation

Monitor the riverbed within 100 metres upstream and downstream of the watermain.

Stockpile appropriately-sized rock near the Project site, for priority scour protection repairs at the water main crossing.

Establish on-call contracts with a qualified registered professional and a qualified marine contractor prior to Tunnel removal, to ensure that scour protection repairs can be designed and implemented on short notice

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|---------------------------------|--|
| <p>Change in flow rates after Tunnel removal.</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects to river hydraulics and river morphology within the Fraser River South Arm.</p> <p>Removal of the Tunnel is not expected to result in any changes in water level or flow splits between the main channel and nearby channels. Suspended sediment load in the Fraser River is naturally high and the temporary increase in suspended sediments anticipated during Tunnel removal is expected to be relatively minor.</p> <p>River Hydraulics and River Morphology are addressed in Section 4.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.1.4</p> |
| <p>Lack of inclusion of Deas Slough and the stagnant waters east by the rowing club in the river hydraulics and morphology study.</p> | <p>Deas Slough and the stagnant waters east by the rowing club were included in the River Hydraulics and River Morphology study. River Hydraulics and River Morphology are addressed in Section 4.1.</p> | <p>Addressed</p> | <p>None</p> |

SEDIMENT AND WATER QUALITY

The proposed bridge will have a clear-span, which reduces potential effects to sediment and water quality within the Fraser River South Arm. During Tunnel decommissioning, a minor, temporary increase in turbidity, as compared with baseline conditions, is anticipated. No appreciable change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated.

Effects

A negligible effect on quality of water used for cultural purposes has been determined.

A negligible effect on quality of experience tied to use of water for cultural purposes has been determined.

Mitigation

Avoid effects through Project design.

Incorporate a stormwater collection and distribution system (stormwater detention ponds and biofiltration swales) into bridge design that will convey and discharge stormwater runoff to appropriate upland infrastructure for proper treatment.

Develop Construction Environmental Management and Operational Environmental Management plans.

Control suspended sediment during Tunnel decommissioning. Employment of construction methods that minimize levels of Project-induced turbidity. Use spoil barges equipped with sediment containment system (filter cloth, concrete lock blocks, straw bales) to transport removed material off-site.

Control suspended sediment during Project construction in and adjacent to Deas and Green Sloughs. Use of sediment control measures such as turbidity curtains and de-watered cofferdams.

Monitor water quality during construction.

Use timing windows for undertaking in-stream works.

Residual & Cumulative Effects

No Project-related residual or cumulative effects on river hydraulics and river morphology or sediment and water quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|--|
| <p>Potential effects of run off from bridge and tunnel decommissioning</p> | <p>The proposed bridge will have a clear-span, which reduces potential effects on sediment and water quality within the Fraser River South Arm associated with Project construction and operation. During Tunnel decommissioning, a minor, temporary increase in turbidity is anticipated. No appreciative change in water quality, related to the re-suspension or re-distribution of sediments during Tunnel decommissioning, is anticipated. Elements of the Project design, including the use of bio-filtration ponds, will provide a benefit by improving the level of treatment of surface runoff from Highway 99. Applying mitigation, including timing windows for undertaking in-stream works, will insure that Project-related effects on water quality are effectively mitigated. No Project-related residual or cumulative effects on sediment and water quality are expected. Sediment and Water Quality is addressed in Section 4.2 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.2.4</p> |

4.4 FISH AND FISH HABITAT

The proposed bridge will have a clear span over the Fraser River South Arm and Deas Slough, avoiding or minimizing Project-related effects on fish and fish habitat. The small area of fish habitat affected by the Project will be offset or improved by proposed habitat enhancements, including restoring Green Slough to its historic alignment, to achieve net environmental benefits for fish and fish habitat. Given the disturbed nature of much of the Project alignment, re-vegetation and restoration of areas within the Project alignment, including under the new bridge and adjacent to relocated ditches, represents an opportunity to provide a net improvement to ecological conditions. The productive capacity of local ecosystems will be enhanced by improvements to local water quality; removal of non-native species; and replanting with species that provide habitat value for fish and wildlife.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

Mitigation

Avoid effects through Project design.

Apply best management and environmental management practices.

Develop Construction Environmental Management and Operational Environmental Management plans.

Use timing windows for undertaking in-stream works.

Erosion and sediment control.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term probability of physical injury or mortality to fish through crushing or entrainment during the construction period.

No significant Project-related residual or cumulative effects on fish and fish habitat are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|--|
| <p>Potential effects to fish and fish habitat, including species of cultural and economic importance such as eulachon, sturgeon, and salmon.</p> <p>Hwlitsum consider the creation and preservation of habitat for fish and wildlife as a key concern and priority.</p> <p>Hwlitsum have a strong connection to the Project area and to the river and are concerned with any additional impacts on fish and fish habitat.</p> <p>Elders are concerned with habitat loss partly due to “the mismanagement of fisheries by DFO” and expressed concerns related to future generations and practice of traditional activities.</p> <p>“What I say about the loss of these fish, including eulachons, is it is death by a 1000 cuts”</p> | <p>The Ministry understands the significance of culturally and economically important fish such as eulachon, sturgeon, and salmon to Hwlitsum and is committed to avoiding or mitigation any potential effects. Fish and Fish Habitat are discussed in Section 4.4</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.4.4</p> |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|--|
| <p>Potential effects of underwater noise generated by Tunnel decommissioning and other construction activities on migrating salmon.</p> | <p>Sources of construction-related underwater noise such as driving piles along the edges of Deas Slough will be temporary in nature. Propagation of underwater noise from these sources can be mitigated effectively by scheduling such activities during periods of low tide, when work can be completed under shall water conditions or in the dry, thereby minimizing potential effects. No Project-related residual or cumulative effects on underwater noise conditions are expected. Underwater Noise and Fish and Fish Habitat are addressed in Sections 4.3 and 4.4 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in 4.3.4 and 4.4.4</p> |

4.6 MARINE MAMMALS

Marine mammals, specifically harbor seals and sea lions, are known to use marine areas within the Project alignment. Other species of conversation interest, including southern resident killer whales, do not occur in the Fraser River.

Underwater noise during construction is the key area of focus for potential Project-related effects on marine mammals. Underwater noise in the Fraser River South Arm from existing sources currently exceeds thresholds for disturbance to marine mammals approximately 20% of the time. The distance from source within which seals could hear underwater noise generated by construction activities is estimated at no more than 7.5 km.

Effects

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

Mitigation

Apply standard industry and best management practices to activities such as pile driving that have the potential to generate underwater noise to ensure sound thresholds for the protection of marine mammals are adhered to.

Marine Mammal Management Plan to be incorporated into the Construction Environmental Management Plan

Monitor underwater noise.

Cumulative Effects

No significant Project-related residual or cumulative effects on marine mammals are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---------------------------|--------|-------------------------|
| Hwlitsum has not voiced any specific issues or concerns with respect to Marine Mammals. | | | |

4.7 VEGETATION

The Highway 99 corridor is a highly developed area and vegetation along the Project alignment reflects the influence of past development.

Project components and activities will be primarily located within the existing Highway 99 right-of-way, where the vegetation consists mainly of grassy, mowed verges. Through Project planning, the Ministry has taken steps to avoid or minimize Project-related effects on at-risk ecosystems, primarily cattail marsh and estuary marsh that occur in the vicinity of the Project. No at-risk vegetation species were observed during field surveys and their presence is unlikely, given the disturbed nature of habitats present.

Effects

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to best management and environmental, terrestrial vegetation and wildlife management practices. Apply best practices such as flagging of at-risk ecosystems to avoid encroachment during construction.

Offset and enhance habitat. Create comparable habitat within the Project alignment to offset unavoidable potential Project-related effect, limited to a small reduction in area of the cattail marsh that overlaps with Project components. Replant disturbed areas with native species.

Invasive species management.

Cumulative Effects

No significant Project-related residual or cumulative effects on vegetation are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Invasive plant species and proposed plans to manage presence during construction.</p> | <p>Mitigation and management of invasive species are presented in Section 4.7 of the Application. The Ministry will develop and implement an Invasive Species Management Plan as part of the Construction Environmental Management Plan.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.7.4 (Vegetation Mitigation Measures)</p> |
| <p>Inclusion of culturally significant plants in planting plans and opportunity for Hwlitsum in the identification of plants, and planting work.</p> | <p>Planting plans will be developed during later stages of Project planning and design. Opportunities for inclusion of culturally significant plants in in planting plans will be considered at that time. The Ministry will consult Aboriginal Groups on the development of these plans.</p> | <p>Addressed</p> | <p>The Ministry will develop planting plans with consultation from Aboriginal Groups</p> |

4.8 TERRESTRIAL WILDLIFE

The Highway 99 corridor is a highly developed area and terrestrial wildlife has generally adapted to this current condition. Terrestrial wildlife along Highway 99 consists primarily of raptors, riverine birds, and small mammals. Barn owl foraging habitat has been identified along vegetated sections of Highway 99 and barn/cliff swallow nesting has been noted under the Deas Slough Bridge. No Pacific water shrew occurrence, and limited habitat potential, was identified within or adjacent to the Project alignment.

Effects

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

Mitigation

Minimize potential effects through Project design.

Adhere to terrestrial vegetation and wildlife management best practices such as spatial and temporal avoidance, pre-construction surveys and nest survey protocols, wildlife salvage and translocation, flagging and management of sensitive areas, and timing window restrictions.

Habitat enhancement and offsetting.

Residual & Cumulative Effects

There is a low, short-term probability of barn swallow habitat loss during the construction period. The new bridge will provide new nesting opportunities for barn swallows.

There is a low, long-term probability of barn owl mortality.

No significant Project-related residual or cumulative effects on terrestrial wildlife are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|--|
| <p>Potential light and noise effects on wildlife</p> | <p>The Ministry understands that Hwlitsum is concerned with the potential effects of light and noise on species such as waterfowl, bats and migratory birds. Construction best practices, including flagging of sensitive wildlife habitat and adhering to least-risk timing windows will ensure construction-related effects on wildlife and wildlife habitat are effectively addressed. Project-related effects on wildlife and wildlife habitat. Potential Project-related effects on terrestrial wildlife are presented in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |
| <p>Potential effects of the bridge structure on species such as waterfowl and migratory birds. Concern with the effects of the Project on species hunted by Hwlitsum such as on ducks and geese</p> | <p>The Ministry understands that Hwlitsum is concerned with the potential effects of the new bridge structure on species such as mammals, waterfowl, bats, eagles and migratory birds including ducks and geese. Installation of flight deflectors such as hedgerows at appropriate locations along the highlight will mitigate potential Project-related increase in traffic collision risk. Terrestrial Wildlife in addressed in Section 4.8 of the Application.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures outlined in Section 4.8.4</p> |

4.9 AIR QUALITY

Ambient air quality in the vicinity of the Highway 99 corridor has improved in recent years and will continue to improve with or without the Project. These projected future improvements are partly linked to reductions in emissions from vehicles as new emission control technologies are phased in.

Project-related reduction in idling due to congestion, and consequent reduction in emissions, is expected to result in further improvement in air quality. Anticipated Project-related improvements by 2031 include a 35% reduction in particulate matter emissions, as compared with a 14% reduction without the Project; a 47% reduction in volatile organic compound emissions, as compared with a 40% reduction without the Project; and no exceedances of the current most stringent air quality objectives for specific air contaminants, as compared with two predicted exceedances without the Project.

The new bridge will also allow for better dispersion of vehicle emissions and avoid accumulation of emission-related air contaminants at specific locations such as at the Tunnel portals, where they accumulate today.

Greenhouse gas emissions from traffic along the Highway 99 corridor are expected to decrease, with or without the Project, as newer engine technologies provide substantial reductions in overall CO₂e emission levels. Project-related reduction in idling due to congestion is anticipated to result in a further 5% to 6% reduction in GHG emissions.

Effects

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

Mitigation

Minimize effects through Project design.

Implement recognized mitigation measures and best management practices that have proven to be effective on other transportation projects.

Development of an Air Quality and Dust Control Management Plan for inclusion of the Construction Environmental Management Plan.

Measure and monitor vehicle emissions and road dust during Project operation.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Hwlitsum has not voiced any specific issues or concerns with respect to Air Quality. | | | |

4.10 ATMOSPHERIC NOISE

The Project is located in an area where ambient noise levels are generally high, dominated by noise from traffic on Highway 99 and connecting roadways. Once the new bridge and upgraded highway become operational, ambient noise levels at the majority of residential receptors along the Project alignment are expected to be lower than current noise levels. Noise levels at parks adjacent to the Project, including Deas Island Regional Park, will increase by varying degrees dependent on the distance from the highway but do not exceed what is acceptable for residential, educational or institutional facilities.

Effects

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

Mitigation

Minimize effects through Project design.

Adhere to construction best practices and the Ministry’s 2014 *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways*.

Develop and implement a Noise Management Plan.

Residual & Cumulative Effects

With the application of mitigation, no significant Project-related residual or cumulative effects on air quality are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---------------------------|--------|-------------------------|
| Hwlitsum has not voiced any specific issues or concerns with respect to Atmospheric Noise. | | | |

5.2 MARINE USE

The Fraser River South Arm supports a variety of marine uses, including deep sea and domestic shipping, materials handling, log storage, and sorting and booming, as well as commercial, recreational and Aboriginal fishing activities. In addition, recreational boating, supported by marinas and a rowing club located in Deas Slough, take place within the vicinity of the Project.

A clear span crossing of the Fraser River is proposed to avoid impacts to marine use and the existing three span Deas Slough Bridge will be replaced with a clear span to improve navigation in and out of the slough.

Project-related effects on marine use may include temporary constraints on access and use of sections of the Fraser River South Arm and Deas Slough during construction.

Effects

A negligible effect on access to instream locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of instream locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Develop and implement a Marine Access Management Plan to ensure that important marine use activities can be reconciled with temporary constraints associated with Project construction.

Establish communications protocols to advise in-stream construction activities.

Ensure appropriate lighting and marking for safe navigation.

Establish navigation protection zones during construction to avoid or minimize impact on marine use.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|---|---------------------------------|---|
| <p>Potential effects of construction during fishing season on fishing activities.</p> <p>Impacts of Tunnel decommissioning on Aboriginal fisheries, specifically as it relates to timing.</p> | <p>Potential interference with Hwlitsum fisheries during bridge construction is addressed in Part C of the Application (in Section 10.1.3.2 and 10.1.3.8.7). A negligible effect to access to river locations for traditional use as a result of changes to the physical characteristics of these locations has been determined.</p> <p>The Ministry understands the importance of working closely with Aboriginal Groups to ensure negative effects are avoided.</p> | <p>Addressed in Application</p> | <p>Ongoing consultation and implementation of mitigation measures outlined in Section 5.2.4</p> |
| <p>Facilitation of increased shipping in the river. “Our concern being a salmon culture is there would be a build-up of ships which makes it impossible for us to fish and puts us in hazardous situations”.</p> | <p>The Project will not appreciably increase the size, or volume, of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Other factors, including the Metro Vancouver water main to the west of the Tunnel, other utility crossings, and the width of the river itself, limit the size of vessels that can navigate the river.</p> | <p>Addressed in Application</p> | <p>None</p> |

5.3 LAND USE

The majority of the Project alignment is located on provincial Crown land, including submerged land on the Fraser River bed, within the existing Highway 99 right-of-way. Land uses in areas adjacent to the highway include agriculture, industrial, institutional, mixed commercial and residential, parkland, and the Vancouver Landfill in Delta.

The Project is consistent with local and regional land use plans, and will support long-term economic growth and encourage denser, land-intensive, high-quality forms of development consistent with such plans. The Project is not anticipated to affect regional growth trends or current trends for industrial land use and development. The Project aligns with adjacent land uses that have evolved along the highway 99 corridor.

Once the new bridge becomes operations, recreational experience in its vicinity is expected to change due to improvements in local air quality, shoreline restoration of Deas Island, and re-vegetation of areas currently supporting highway infrastructure; improved connectivity across the Deas Island Regional Park resulting from removal of the Tunnel portals; and shading adjacent to the bridge, overhead noise, and changes in local viewsapes.

The Project will not result in changes to existing land use beyond small amounts of land, outside of the existing right-of-way, that area required for the Project.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

Mitigation

Minimize effects through Project design.

Address temporary effects on existing land use during construction and incorporate land use considerations into a Traffic Management Plan.

Incorporate land use considerations into a Marine Construction Plan.

Reconnect recreational trails.

Residual & Cumulative Effects

There is a high, short-term probability of disturbance to residential, commercial and industrial land uses.

There is a high, short-term probability of disturbance to recreational uses near the new bridge.

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|--|--|---------------|--------------------------------|
| Interest in the inclusion of a single multi-use pathway. | The Project will include multi-use pathways on both sides of the new bridge, which will provide new and enhanced opportunities for cycling and pedestrians, as well as enhanced connections to community trails and cycling routes for interchange and overpass reconstructions. | Addressed | None |

5.5 VISUAL QUALITY

The new bridge will add noticeable visual features to the landscape and will change visual conditions adjacent to the Project alignment. Replacement of interchanges also has the potential to change visual conditions of these locations. At distances greater than one kilometer, the bridge deck will merge with the natural landscape and the main visual features will be the bridge towers. Changes in visual quality at interchanges will be minor as visual quality in such areas is currently influenced by existing transportation infrastructure.

Effects

During construction, no to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

During operation, a measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Minimize effects through Project design.

Use of vegetated buffers to minimize visual effects to residential developments within close proximity to the bridge in Delta.

Residual & Cumulative Effects

There is a moderate, long-term probability of disturbance to visual quality.

No significant Project-related residual or cumulative effects on marine access are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---------------------------|--------|-------------------------|
| Hwlitsum has not voiced any specific issues or concerns with respect to Visual Quality. | | | |

6.1 HERITAGE RESOURCES

The Project is located in an area where substantial historical development has occurred and the majority of the Project alignment is characterized as having low archaeological potential. No archaeological or historical sites were found within the Project alignment during the field inventory of the Project area.

Effects

A negligible effect on access to upland locations for traditional use has been determined.

A negligible effect on quality of experience tied to access of upland locations for traditional has been determined.

During construction, no to negligible effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

During operation, a measurable effect on quality of experience while engaged in or tied to traditional use as a result of changes to the cultural landscape.

Mitigation

Develop and implement a Heritage Resources Management Plan, which will include a change find procedure, to avoid impacts to previously unknown heritage resources that may be encountered during Project construction and operation.

Undertake additional archaeological surveys.

Residual & Cumulative Effects

No significant Project-related residual or cumulative effects on heritage resources are expected.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|--|---------------------------------|--|
| <p>Protection of archaeological and heritage resources, including intangible heritage sites and specific concern for any effects on the ǻǻqtinǻs/Tl'uqtinus site and potential archaeological values at interchanges.</p> | <p>The Ministry acknowledges that protection of archaeological sites as well as intangible heritage sites are of utmost importance to Hwlitsum.</p> <p>All Aboriginal Groups have been provided with a comprehensive list of these sites, the Archaeological Overview Assessment, the Archaeological Impact, and Heritage Resources Overview Assessment.</p> <p>Appropriate measures will be taken to ensure the protection of archaeological and heritage resources as outlined in Section 6.1.</p> | <p>Addressed in Application</p> | <p>Implementation of mitigation measures as outlined in Section 6.1.4</p> |
| <p>Participation in archaeological fieldwork and review of archaeological draft reports.</p> | <p>Hwlitsum will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports</p> | <p>Addressed</p> | <p>Hwlitsum will be invited to participate in any additional archaeological fieldwork required for the Project and will have an opportunity to review related reports.</p> |

7.0 HUMAN HEALTH

Predicted Project-related improvements in local and regional air quality, primarily due to reductions in congestion-related idling, are anticipated to have a positive effect on human health. The Project is anticipated to improve health equity by providing disadvantaged groups with better access to reliable transportation options. The Project will result in additional health benefits related to greenhouse gas emissions reductions, increased active and public transportation, improved traffic safety, improvement connectivity and access, improved emergency response, and economic development opportunities.

Future Project-related consultation with Aboriginal groups represents an important opportunity to address health interests specific to Aboriginal communities that have been identified in the health impact assessment.

Planned future engagement with a broad range of stakeholders will help to optimize Project benefits associated with improvements to active transportation options such as cycling, addressing safety and security considerations, and emergency response.

Effects

A negligible effect on the availability of fish resources for traditional use has been determined.

A negligible effect on quality of fish resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of fish resources has been determined.

A negligible effect on the availability of marine mammal resources for traditional use has been determined.

A negligible effect on quality of marine mammal resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of marine mammal resources has been determined.

A negligible effect on the availability of vegetation resources for traditional use has been determined.

A negligible effect on quality of vegetation resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of vegetation resources has been determined.

A negligible effect on the availability of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of terrestrial wildlife resources for traditional use has been determined.

A negligible effect on quality of experience tied to the traditional use of terrestrial wildlife resources has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in air quality has been determined.

No, negligible or measureable effect on quality of experience with engaged in or tied to traditional use as a result in noise has been determined.

No or negligible effect on quality of experience with engaged in or tied to traditional use as a result in ground-borne vibration has been determined.

| 7.0 HUMAN HEALTH | | | |

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Hwlitsum has not voiced any specific issues or concerns with respect to Human Health. | | | |

8.0 ACCIDENTS AND MALFUNCTIONS

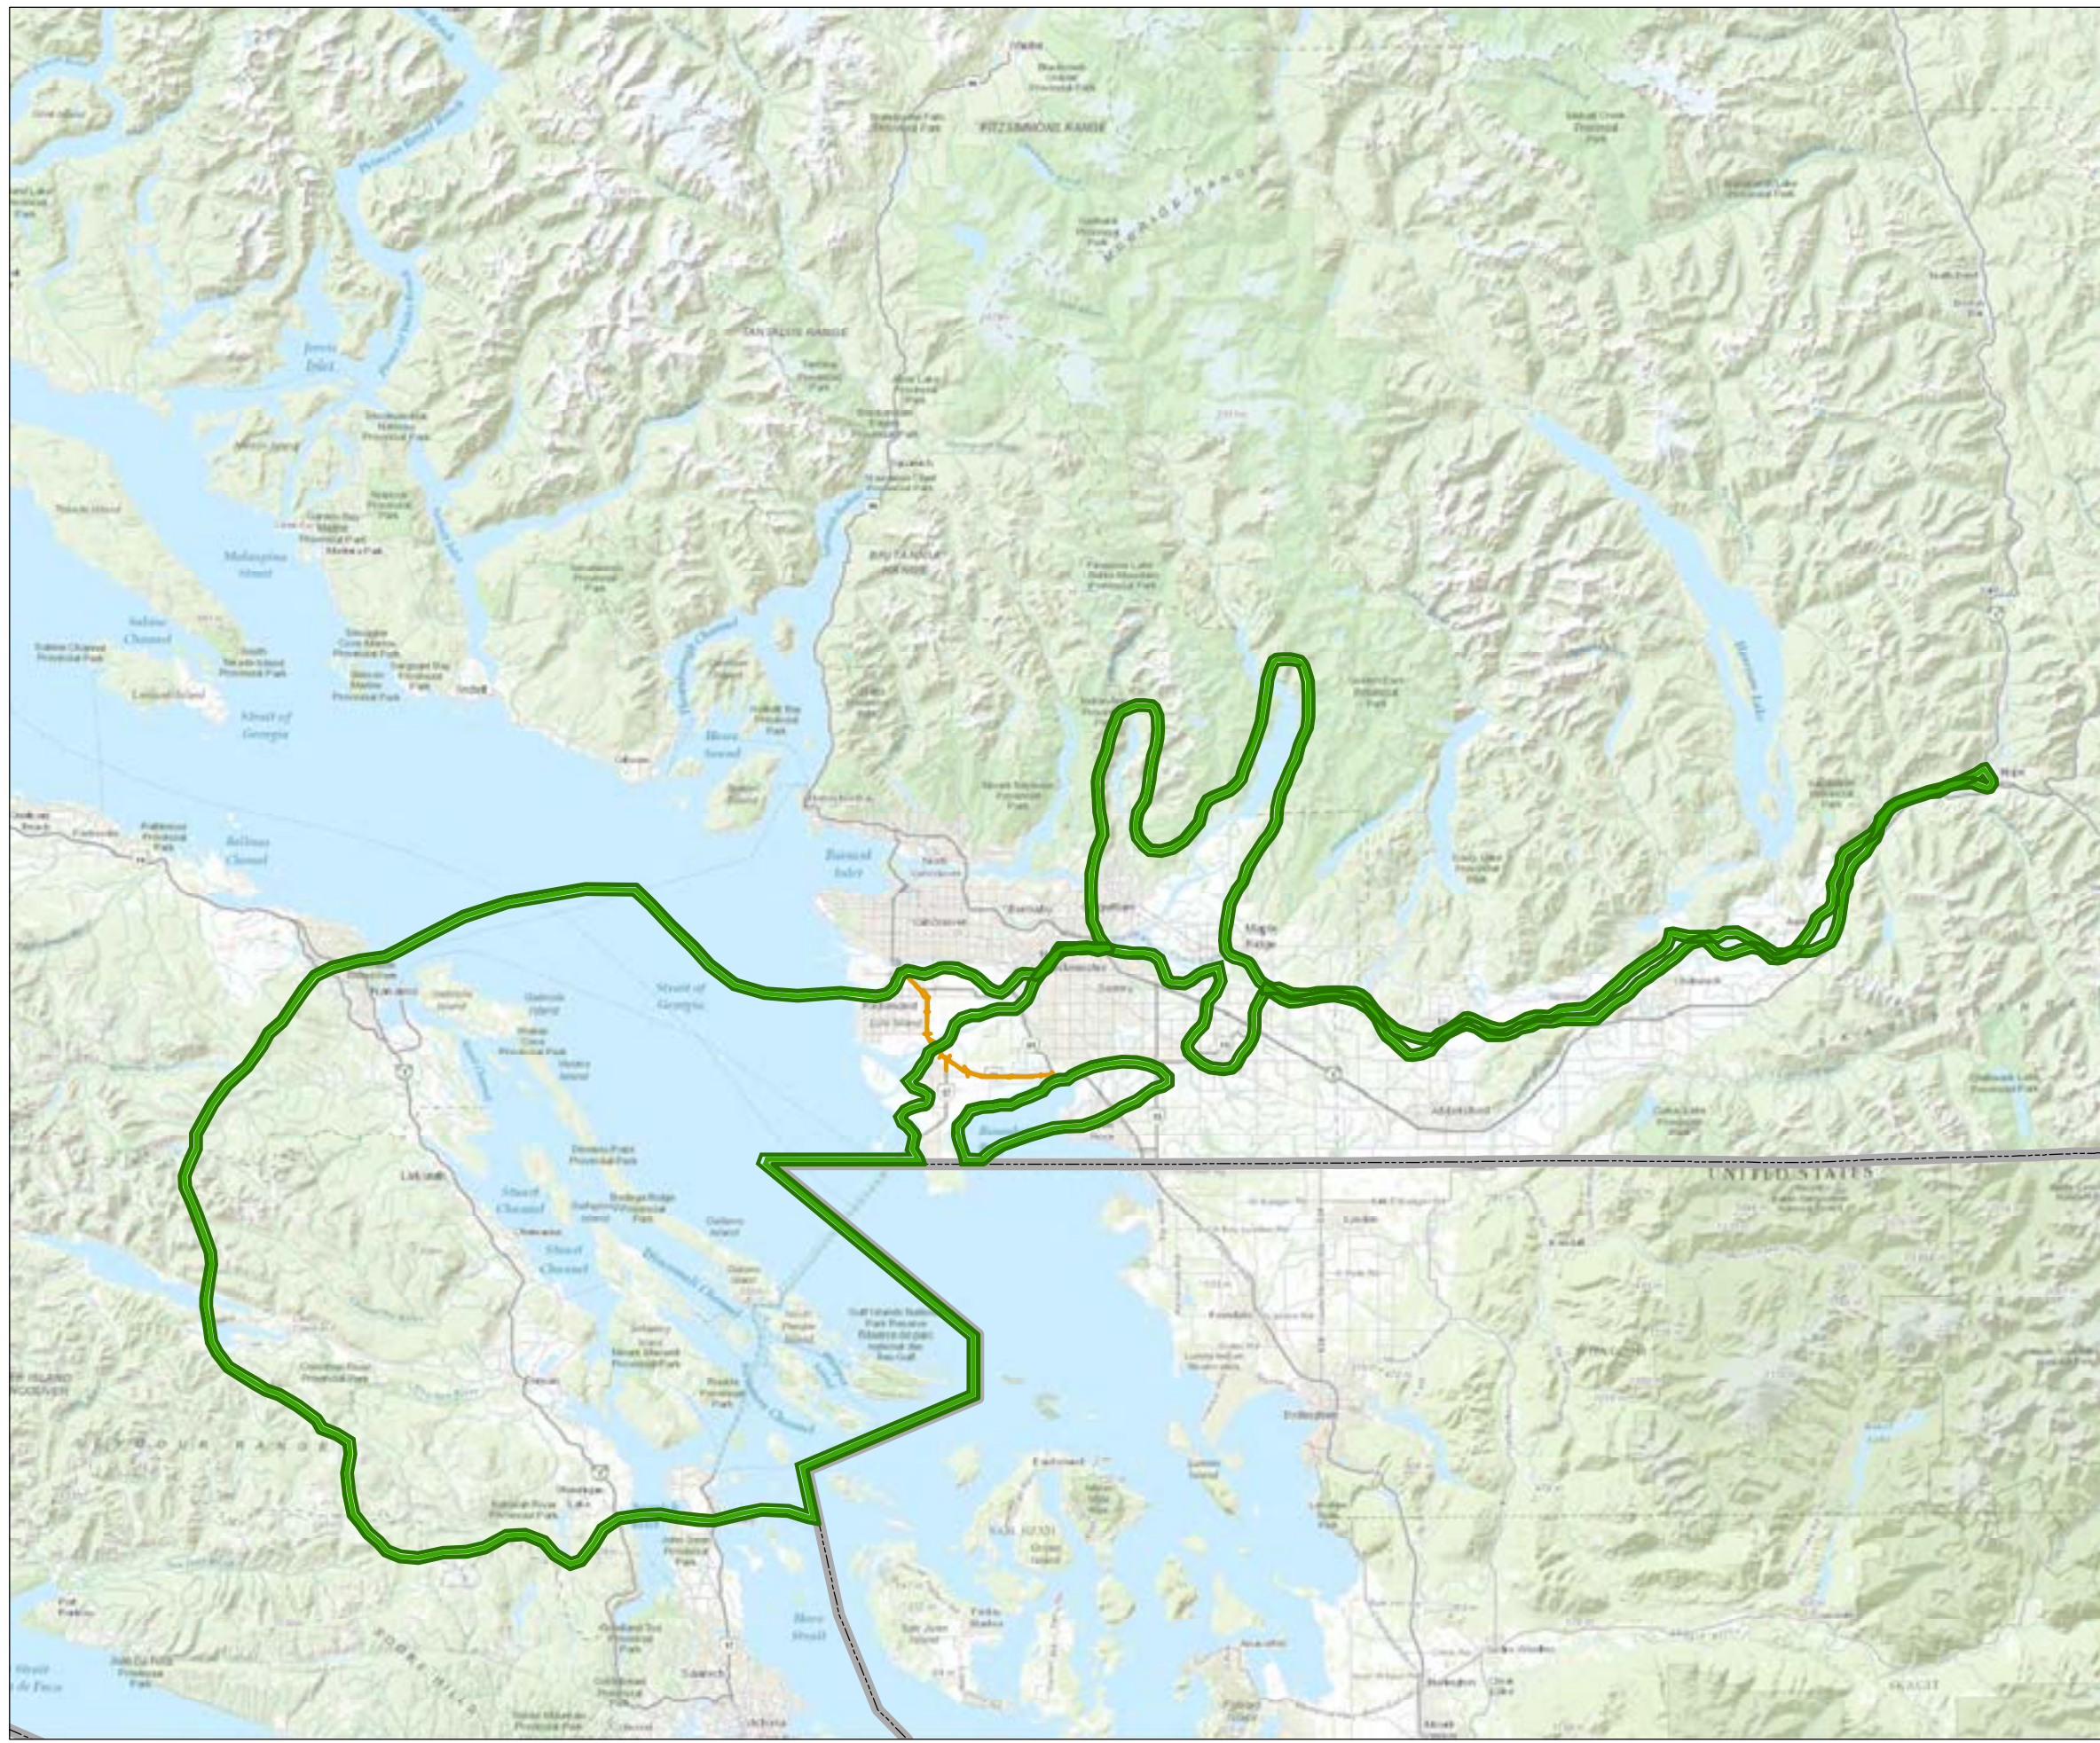

Adherence to the practices and procedures contained in the Construction Environmental Management Plan will minimize the potential for accidents and malfunctions to occur.

In general, replacement of the Tunnel with a new crossing and the proposed highway improvements are expected to lower the risk of accidents and malfunctions during highway operations and maintenance.

| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
|---|---|--------------------------|--|
| Spills of hydrocarbons from refueling or leaks in construction equipment/vessels, including human waste. Spills from accidents during construction and operations | An Emergency Response and Spill Contingency Plan will outline how construction personnel will prevent, prepare for, respond to, and clean up spills | Addressed in Application | Implementation of mitigation measures outlined in Section 12.1.5 (Emergency Response and Spill Contingency Plan) |

| OTHER ISSUES | | | |
|---|--|---------------|--|
| Consultation with Hwlitsum identified issues outside of the environmental assessment process, Aboriginal Interests, Aboriginal Consultation, Aboriginal Participation and Project-Related Opportunities, and sections of the Application. | | | |
| Issues | Proponent Response/Action | Status | Next Steps by Proponent |
| Potential for falling snow and ice | The design of the new bridge is similar to the Alex Fraser Bridge, with cable stays on the outside of the span. There are no cables crossing the deck. Snow and ice control measures will be reflected in the bridge design. | Addressed | Inclusion of snow and ice control measures in bridge design. |

Part D – Public Consultation

11.0 Public Consultation

Planning and engagement for the Project has been underway since 2012. During this time, the Ministry has been working to raise awareness of the Project, receive feedback from stakeholders and interested parties, and respond to Project related enquires.

The main purpose of the Project’s public consultation program is to ensure that members of the general public (the public), and local governments, residents, property owners, other rights holders and interest groups (collectively described as stakeholders) have an opportunity to become informed and provide meaningful input throughout Project development, before, during and after the EA process. This includes ensuring that the consultation fulfills EAO’s requirements for the purpose of the provincial EA.

This section of the Application describes the public consultation activities that have been undertaken before entering the EA process and during the pre-Application phase through to Application submission. This section also describes the activities that are being undertaken during the review phase of this Application. Information regarding consultation with Aboriginal Groups can be found in **Section 10.0 Aboriginal Consultation** of the Application.

11.1 Background Information

This section identifies the stakeholders who have been identified as being potentially affected by the proposed Project.

11.1.1 Stakeholder Identification

The Project’s public consultation program has been designed to reach a wide variety of stakeholders and the public. Since 2012, the Ministry has been working to identify, meet with and keep informed a broad list of stakeholders who may be interested in or affected by the Project. These include:

Regulatory Agencies:

- Provincial
 - Agricultural Land Commission
 - B.C Environmental Assessment Office
 - B.C. Ministry of Agriculture

- B.C Ministry of Environment
- B.C Ministry of Forests, Lands, and Natural Resource Operations
- B.C Ministry of Transportation and Infrastructure
- Federal
 - Canadian Environmental Assessment Agency
 - Environment and Climate Change Canada
 - Fisheries and Oceans Canada
 - Transport Canada
 - Port of Vancouver

Provincial and Federal Elected Officials:

- Federal Members of Parliament (MP)
 - Honourable Marc Garneau, Minister of Transport, MP Notre-Dame-de-Grâce–Westmount
 - Honourable Carla Qualtrough, Minister of Sport and Persons with Disabilities, MP Delta
 - Joe Peschisolido, MP Steveston - Richmond East
- Provincial Members of the Legislative Assembly (MLA)
 - Honourable Linda Reid, Speaker of the Legislative Assembly and MLA Richmond East
 - John Yap, MLA Richmond - Steveston
 - Honourable Teresa Wat, Minister of International Trade and Minister Responsible for the Asia Pacific Strategy and Multiculturalism, MLA Richmond Centre
 - Honourable Peter Fassbender, Minister of Community, Sport and Cultural Development, and Minister Responsible for TransLink, MLA Surrey Fleetwood
 - Honourable Stephanie Cadieux, Minister of Children and Family Development, MLA Surrey Cloverdale
 - Marvin Hunt, MLA Surrey Panorama
 - Honourable Amrik Virk, Minister of Technology, Innovation and Citizens' Services, MLA Surrey Tynehead
 - Gordon Hogg, MLA Surrey White Rock
 - Scott Hamilton, MLA Delta – North
 - Vicki Huntington, MLA Delta –South

Local Elected Officials and Governments:

- Local and Regional Government Staff, Council and Organizations
 - Corporation of Delta, staff and Council
 - City of Richmond, staff and Council
 - City of Surrey, staff
 - City of Vancouver, staff
 - City of White Rock, staff
 - Fraser Health Authority, staff
 - Metro Vancouver, staff
 - TransLink, staff
 - Vancouver Coastal Health, staff

Other interested Groups and Organizations:

- Agricultural organizations
 - Delta Farmers' Institute
 - Richmond Farmers' Institute
 - Individual farmers whose properties are adjacent to the Project area
- Businesses and business organizations that rely on Highway 99 for goods and service movements and access for their customer base, such as:
 - BC Chamber of Commerce
 - Delta Chamber of Commerce
 - Richmond Chamber of Commerce
 - Greater Vancouver Board of Trade
 - Ladner Business Association
 - Tsawwassen Business Association
 - BC Trucking Association
 - Vancouver Airport Authority (YVR)
 - Boundary Bay Airport
 - Western Stevedoring/Coast 2000
 - London Drugs
 - FedEx

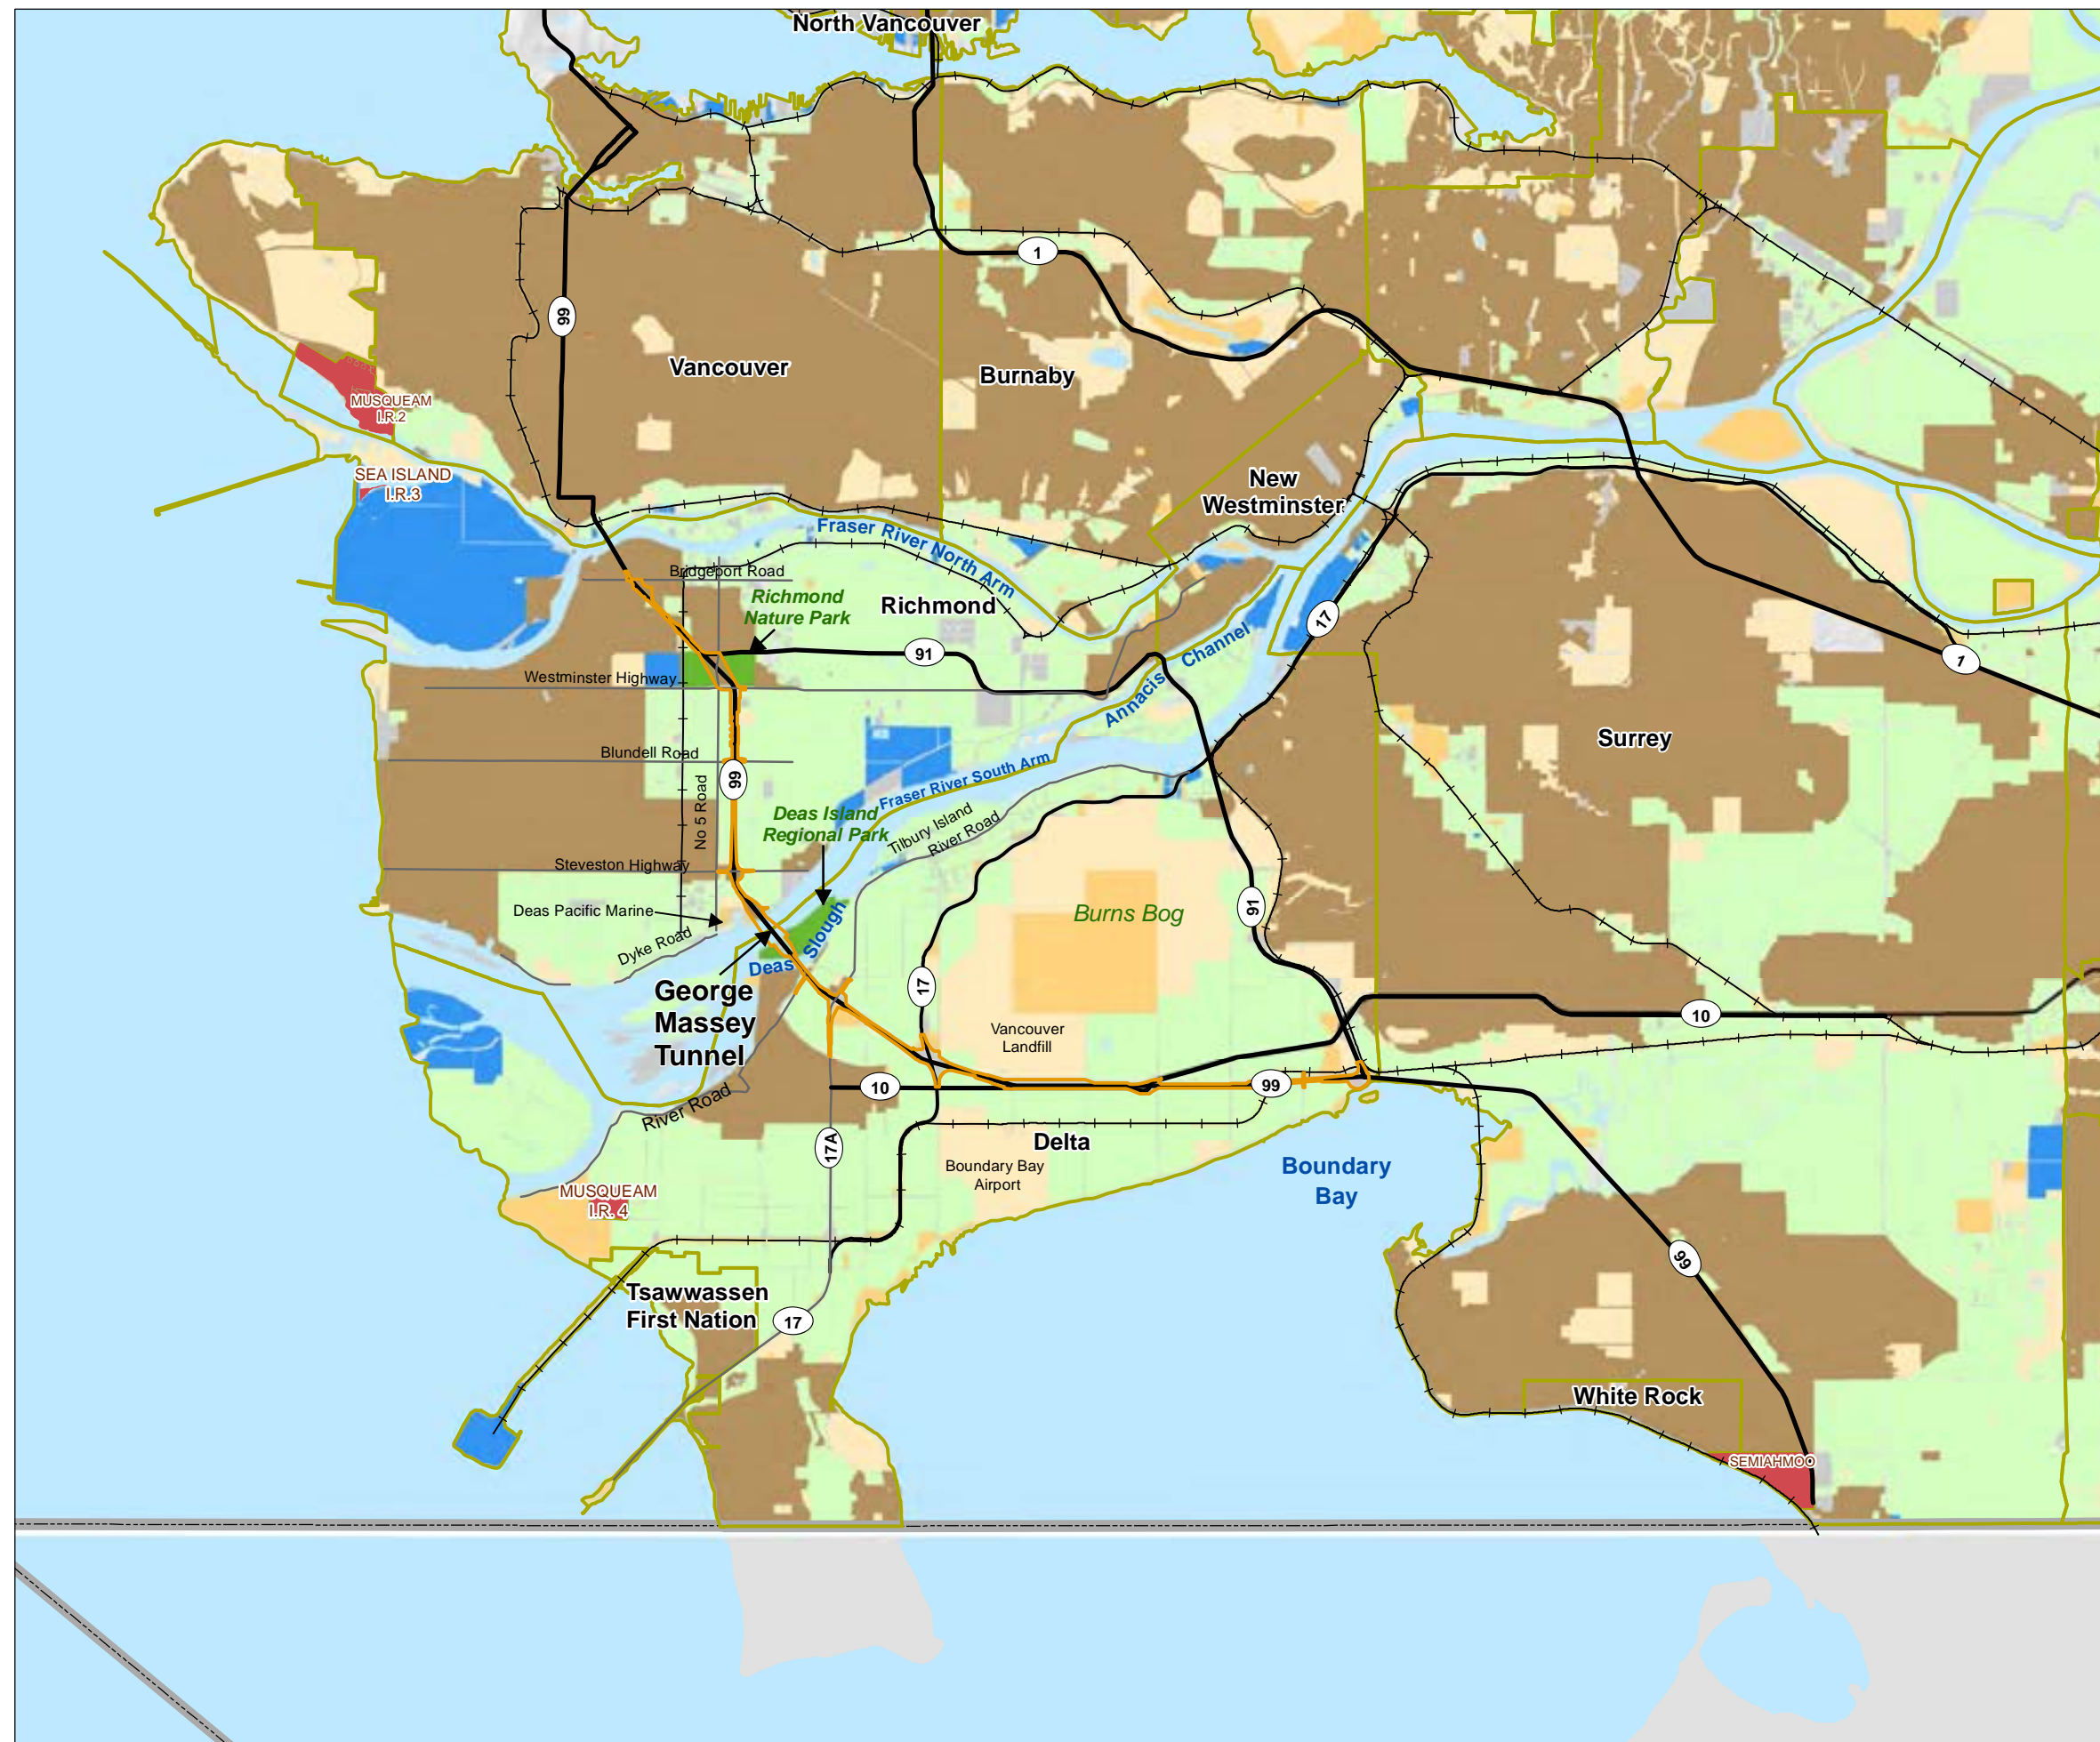

- Commercial and recreational marine users, including:
 - Amix Marine Services Ltd.
 - BC Ferries
 - BC Marine Terminal Operators Association
 - BC Seafood Alliance
 - Bridgeview Marine
 - Britannia Heritage Shipyard Park
 - Canadian Coast Guard
 - Captain's Cove Marina
 - Catherwood Towing
 - Coast Pilot
 - Council of Marine Carriers
 - Crosby Marine Film Services
 - C-Tow
 - Deas Harbour Marina
 - Emergency Management BC
 - Fish Safe BC
 - Forrest Marine
 - Fraser River Pile & Dredge Inc.
 - Fraser River Pilots
 - Fraser Surrey Docks Ltd.
 - Global Container Terminals Canada
 - Harken Towing Co. Ltd.
 - Hodder Tug Co. Ltd.
 - Island Tug & Barge Marine (ITB)
 - Island View Marina
 - Lafarge Canada
 - Ledcor Marine
 - Ledcor Resources & Transportation
 - Lehigh Cement
 - Local Rotary Clubs

- Maersk Canada
- Mercury Launch & Tug Ltd.
- North Arm Transportation Ltd.
- Pacific Custom Log Sorting
- Pacific Pilotage Authority
- Pacific Towing Services
- Riverhouse Marina
- Safe Harbour Marine
- Samsun Tug Boats Inc.
- Seaspans Ferries
- Seaspans Marine Corporation
- Shelter Island Marina
- SMIT Harbour Towing Vancouver Inc
- SMIT Marine Canada Inc
- Steveston Water Taxi
- The Marine Service Network
- Valley Towing Ltd
- Vancouver Mobile Marine
- Vancouver Pile Driving Ltd
- West Coast Fuel & Transport Ltd
- Western Canada Marine Response Corporation (WCMRC)
- Local emergency responders, including:
 - BC Ambulance
 - Delta Fire
 - Delta Police
 - RCMP - Deas Highway Patrol
 - RCMP – Lower Mainland District
 - RCMP – Richmond
 - Richmond Fire

- Community and resident groups in Delta, Richmond, Surrey and southwest Vancouver
Cycling organizations representing recreational and commuter cyclists, including:
 - Cycling BC
 - BC Cycling Coalition
 - Borderline Cycling Club
 - Cross Canada Cycle Tour Society
 - Richmond Cycling Committee
 - Tour de Delta
 - Cycling HUB Delta
 - Cycling HUB Greater Vancouver
 - Cycling HUB Richmond
 - Cycling HUB (formerly Vancouver Area Cycling Coalition)
 - Cycling HUB Safe Route Tsawwassen
 - Cycling HUB Surrey
 - Cycling HUB Surrey/North Delta/White Rock
 - Richmond Community Cycling Committee
- Environmental and naturalist organizations, including:
 - Burns Bog Conservation Society
 - Ducks Unlimited
 - Reifel Bird Sanctuary
 - Nature Vancouver
 - Garden City Conservation Society
 - Delta Naturalist Society
 - Earthwise Society
- Land-based recreation organizations, including:
 - Deas Island Regional Park users and trail users on both sides of the Fraser River
 - Delta Community
 - Delta Deas Rowing Club
 - Deas Island Yacht Club
 - Delta Marine Rescue Society
 - Delta Outriggers

- Delta Racing Canoe
- Ladner Business Association
- Model Airplane Club
- Steveston Community Society
- UBC Boathouse
- Property owners adjacent to Highway 99 within the Project boundaries
- Other members of the public

Figure 11.1-1 shows the locations of municipal boundaries, private land and crown land.

11.1.2 Stakeholder Profiles

Based on engagement with key stakeholders over the past three years since the Project was announced, the Ministry has compiled summary information pertaining to the interests of primary stakeholders including local governments and regulatory agencies, as summarized in **Table 11.1-1** below.

Table 11.1-1 Project Stakeholder Background Information

| Stakeholder | Questions and Interests | Background |
|---|---|---|
| Agricultural Land Commission | <ul style="list-style-type: none"> • Interest in potential agricultural effects and benefits including <ul style="list-style-type: none"> ▫ Reliability of getting goods to market ▫ Cross highway connectivity ▫ Drainage and irrigation ▫ Applicable mitigation measures • Interest in land impacts to existing farms and the potential for a net positive gain in available agricultural land • Recommended meeting with farming groups and individual farmers | <ul style="list-style-type: none"> • An independent administrative tribunal dedicated to preserving agricultural land and encouraging farming in British Columbia. The purpose of the Agricultural Land Commission as set out in Section 6 of the <i>Agricultural Land Commission Act</i> is a) to preserve agricultural land; b) to encourage farming in collaboration with other communities of interest; and c) to encourage local governments, Aboriginal Groups, the government and its agents to enable and accommodate farm use of agricultural land and uses compatible with agriculture in their plans, bylaws, and policies. |
| Canadian Environmental Assessment Agency | <ul style="list-style-type: none"> • Limited interest in the Project given that it does not trigger a federal review under the <i>Canadian Environmental Assessment Act, 2012</i> | <ul style="list-style-type: none"> • A federal body accountable to the Minister of Environment and Climate Change. The Agency provides environmental assessments that contribute to informed decision making, in support of sustainable development. The Agency is the responsible authority for most federal environmental assessments. |

| Stakeholder | Questions and Interests | Background |
|------------------------------------|--|--|
| <p>Corporation of Delta</p> | <ul style="list-style-type: none"> • Council supports the Project • Council supports extending River Road underneath the new bridge (improvement under Delta’s jurisdiction) • Staff have discussed potential environmental and recreational improvements • Staff have asked questions about Project scope details • Staff reviewed the proposed list of EA key areas of study in advance of, and as part of, the EA pre-Application | <ul style="list-style-type: none"> • The Corporation of Delta is one of two municipalities through which the Project runs. Delta encompasses 180 square kilometres bordered by the Fraser River on the north, the United States border and Boundary Bay on the south, the City of Surrey on the east and the Strait of Georgia on the west. With the support of a strong farming and agricultural foundation, Delta has grown into three thriving communities: Ladner, Tsawwassen, and North Delta. The municipality also has one of the fastest growing industrial areas in Greater Vancouver. |
| <p>City of Richmond</p> | <ul style="list-style-type: none"> • Council has expressed a preference for a new tunnel or upgrades to the existing Tunnel. • Council supports the following objectives for the Project: <ul style="list-style-type: none"> ▫ Zero or net positive effects on agricultural land ▫ New lanes dedicated for specific use and the new bridge supports alternative transportation modes ▫ Improved travel times and reliability and reduction of GHGs ▫ Connections for pedestrians and cyclists at either end of the bridge ▫ Aesthetically pleasing architectural design for the new bridge ▫ Facilitate sustainable transportation including future rapid transit | <ul style="list-style-type: none"> • The City of Richmond is one of two municipalities through which the Project runs. Richmond is a unique island city comprised of a series of islands (Sea Island, most of Lulu Island, and fifteen smaller islands) nested in the mouth of the Fraser River. Neighboring communities are Vancouver and Burnaby to the north, New Westminster to the east, and Delta to the south. The Strait of Georgia forms its western border. Richmond has been experiencing growth and change, transforming from a rural, local community to an international city with a balance of urban, sub-urban family, and rural areas. |

| Stakeholder | Questions and Interests | Background |
|------------------------------|--|---|
| | <ul style="list-style-type: none"> • Council requested staff to analyze and report back on the Project’s potential implications for Richmond • Staff have requested information about traffic patterns particularly with regard to Oak St. Bridge, Knight St Bridge, Blundell Road Overpass and Steveston Highway Interchange. • Staff reviewed the proposed list of EA key areas of study in advance of, and as part of, the EA pre-Application • Staff advised that the City has environmentally sensitive designated areas in the Project area, including in the Fraser River, that should be protected • Questions about the potential effects of the Vancouver Airport Fuel Facility pipeline currently in development within the Project area | |
| <p>City of Surrey</p> | <ul style="list-style-type: none"> • Recognize the need for the Project and request consideration of additional scope including replacing older Highway 99 interchanges within the City of Surrey | <ul style="list-style-type: none"> • The City of Surrey is a municipality immediately adjacent to the southern/eastern terminus of the Project. Surrey is the 2nd largest city in BC, with over 6000 acres of parkland and green space. |

| Stakeholder | Questions and Interests | Background |
|---|--|--|
| <p>City of Vancouver</p> | <ul style="list-style-type: none"> • Request consideration of short-term improvements at SFPR/Highway 99 to facilitate northbound Highway 99 access to the Vancouver Landfill • Indicated the City likely will defer to Metro Vancouver staff with respect to the Environmental Review | <ul style="list-style-type: none"> • The City of Vancouver is a municipality immediately adjacent to the northern terminus of the Project. Vancouver is located on the western half of the Burrard Peninsula, bound to the north by English Bay and the Burrard Inlet and to the south by the Fraser River. The City of Burnaby lies to the east and the Strait of Georgia to the west. |
| <p>City of White Rock</p> | <ul style="list-style-type: none"> • Recognize the need for the Project and request to be kept informed as planning continues • Request consideration of improvements for local access from Highway 99 to White Rock when border traffic causes congestion | <ul style="list-style-type: none"> • The City of White Rock is a municipality adjacent to the southern terminus of the Project. White Rock is located in the southwest corner of the Lower Mainland, 45 kilometres from Vancouver and only five minutes to the Canada/US border. |
| <p>Environment and Climate Change Canada</p> | <ul style="list-style-type: none"> • Interest from an air quality and wildlife perspective | <ul style="list-style-type: none"> • Environment and Climate Change Canada is a federal ministry mandated to protect the environment, conserve the country's natural heritage, and provide weather and meteorological information. |
| <p>Fisheries and Oceans Canada</p> | <ul style="list-style-type: none"> • DFO has indicated they will likely have more involvement during Tunnel decommissioning activities. | <ul style="list-style-type: none"> • Fisheries and Oceans Canada is a federal agency responsible for managing Canada's fisheries and safeguarding its waters. The department supports strong economic growth in our marine and fisheries sectors by supporting exports and advancing safe maritime trade. |

| Stakeholder | Questions and Interests | Background |
|---|---|--|
| Metro Vancouver. | <ul style="list-style-type: none"> • Interest in: <ul style="list-style-type: none"> ▫ Use and connectivity of Deas Island Regional Park ▫ Potential Project related effects on Metro Vancouver utilities ▫ Potential Project related effects on air quality ▫ Potential Project related changes in traffic and growth patterns • Staff reviewed and commented on the proposed list of EA key areas of study in advance of, and as part of, the EA pre-Application | <ul style="list-style-type: none"> • Metro Vancouver is a partnership of 21 municipalities, one Electoral Area and one Treaty First Nation that collaboratively plans for and delivers regional-scale services. Its core services are drinking water, wastewater treatment and solid waste management. Metro Vancouver also regulates air quality, plans for urban growth, manages a regional parks system and provides affordable housing. The regional district is governed by a Board of Directors of elected officials from each local authority. |
| B.C. Ministry of Environment | <ul style="list-style-type: none"> • Interest in potential Project effects on air quality, wildlife, and contaminated sites | <ul style="list-style-type: none"> • The Ministry of Environment is responsible for the protection, management and conservation of B.C.'s water, land, air and living resources. Its expertise in science, research and analysis are central to supporting all its responsibilities. |
| B.C. Ministry of Forest, Lands and Natural Resource Operations | <ul style="list-style-type: none"> • Discussed heritage resources as it pertains to the Project • Discussed FLNR's approach to permitting for the construction phase • Interest in potential Project related effects on dikes | <ul style="list-style-type: none"> • The Ministry of Forests, Lands and Natural Resource Operations is the Province's land manager, responsible for stewardship of Provincial Crown land, cultural and natural resources. The Ministry ensures the sustainable management of forest, mineral and land-based resources, supports activities that lead to benefits for all British Columbians both economically and environmentally, and facilitates public access to a wide range of activities such as hunting, fishing and recreation. |

| Stakeholder | Questions and Interests | Background |
|---|---|---|
| <p>TransLink</p> | <ul style="list-style-type: none"> • Staff worked with the Project team to ensure that traffic modelling undertaken by both agencies is consistent • Staff's analysis suggests that improvements would help address current and future congestion • At Metro Vancouver's request, staff coordinated an independent assessment of the potential effects of an eight-lane bridge on the regional transportation network • Staff requested additional scope for transit improvements, which was incorporated into the Project design | <ul style="list-style-type: none"> • TransLink is Metro Vancouver's regional transportation authority, responsible for regional transit, cycling and commuting options as well as Intelligent Transportation System programs. TransLink is responsible for the planning, financing and managing of all public transit in addition to major regional roads and bridges. |
| <p>Vancouver Fraser Port Authority</p> | <ul style="list-style-type: none"> • Supports the Project as an improvement for port-related container truck movements • Concerns about new bridge height; want to ensure that marine navigation is protected • Recommended convening meeting with marine users • Input on air quality aspects of the environmental assessment • Interest in current and future port-related transportation needs in the Fraser Richmond Lands area | <ul style="list-style-type: none"> • The Vancouver Fraser Port Authority is responsible for the stewardship of federal port lands in and around Vancouver. It was established by the Government of Canada pursuant to the <i>Canada Marine Act</i> and is accountable to the federal Minister of Transport. Their mandate is to facilitate Canada's trade objectives, ensuring goods are moved safely, while protecting the environment and considering local communities. |

| Stakeholder | Questions and Interests | Background |
|--|---|---|
| <p>Delta Farmers' Institute and Richmond Farmers' Institute</p> | <ul style="list-style-type: none"> • Support the Project as a means to improve speed and reliability of getting goods to market, improving cross-highway travel and improving drainage and irrigation for properties along Highway 99 • Support for the Project as an opportunity to incorporate median barriers on Highway 99 to help with flood control • Interest in ensuring no net loss of farm land • Concerns about potential salt wedge migration and its effect on irrigation if future river dredging were to occur | <ul style="list-style-type: none"> • The purpose of the Delta Farmer's Institute is to a) promote and enhance the agricultural industry in the community of Delta; b) to engage with the Ministry of Agriculture (Federal and Provincial) and the Municipality of Delta; c) to improve relationships between the agricultural industry and the agricultural community in Delta, the Ministry of Agriculture and the Municipality of Delta; and d) to work in unison and agreement to address the issues, concerns and policies of the agricultural industry and community in the Municipality of Delta. • The Richmond Farmers Institute is an independent association of Richmond-based farmers that provide networking and advocacy support for local farmers to address key issues and concerns. The Richmond Farmers Institute nominates five of its members for the Richmond Agriculture Advisory Committee. |
| <p>First Responders</p> | <ul style="list-style-type: none"> • Support the Project as a means to improve safety and to improve access and response time, as well as safety of first responders, in the event of an incident • Numerous suggestions for specific Project scope elements to improve enforcement and emergency response on Highway 99 | <ul style="list-style-type: none"> • First responders are emergency service personnel; police, fire and ambulance who respond to emergencies and incidents. |
| <p>Marine Users</p> | <ul style="list-style-type: none"> • Interest in marine access and potential restrictions during construction | <ul style="list-style-type: none"> • Marine users include user groups that participate in marine activities (e.g., fishing, shipping, kayaking). |

| Stakeholder | Questions and Interests | Background |
|------------------------------|---|--|
| <p>General Public</p> | <ul style="list-style-type: none"> • General support for the Project overall and interest in more detail about specific elements including interchange designs, traffic forecasts, and the environmental assessment • Strong support for capacity improvements to address congestion • Strong support for proposed transit, cycling and pedestrian measures • Support for the proposed interchange improvements • Most participants who commented about tolls supported tolling as a funding mechanism; however, many participants suggested that tolling should be applied in the context of a regional tolling policy • Concerns about potential increased traffic congestion at the Oak Street Bridge and, to a lesser extent, other Fraser River North Arm crossings • Interest in greenhouse gas emissions • Interest in Tunnel decommissioning and potential for increased activity within the Fraser River South Arm | <ul style="list-style-type: none"> • General public includes residents and businesses from municipalities adjacent to Highway 99 who use or cross the Highway for general travel needs; community groups, recreational groups, environmental groups, transit users, etc. with interest in how the Project will affect their use of the corridor, their community economy or livability, or the natural environment. |

11.2 Summary of Past and Planned Consultation Activities

The consultation activities undertaken, or proposed to be undertaken, by the Ministry are described below.

11.2.1 Public Consultation Plan

A Public Consultation Plan was prepared and posted to EAO's website on January 6, 2016 (http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39675.html). This plan describes the consultation activities that had occurred up to issue of the section 10 Order on December 16, 2015, as well as proposed consultation to be undertaken by the Ministry throughout the pre-Application and Application review phases of the EA.

The Public Consultation Plan is based on best practices and input received through consultation up until finalization of the plan, and is intended to meet pre-Application and Application review phase consultation requirements under the Public Consultation Policy Regulation (BC Reg. 363/2002) and the B.C. *Environmental Assessment Act* (B.C. *EAA*), as well as to satisfy the requirements for public consultation established by EAO in its letter to the Ministry of January 7, 2016 (http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39676.html), and under EAO's section 11 Order, issued on March 7, 2016 (http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39946.html) under the B.C. *EAA* that such a Plan be developed and approved by EAO. The Ministry has made no changes or updates to the Public Consultation Plan for the Project since it was approved by EAO.

The key objective of the public consultation program is to provide stakeholders with an opportunity to become informed and provide meaningful input toward the development of the Project, before, during, and after the Application process.

Objectives of the Public consultation program as outlined in the Consultation Plan are to:

Inform people about the Project and the opportunities to provide input – This includes but is not limited to building awareness of the Project through undertaking consultation, having a Project Office where people can ask questions and provide feedback, maintaining a Project website with current and background information, inviting and responding to enquiries, attending presentations and community meetings on request and convening meetings of stakeholders as appropriate.

Ensure that public input is considered in refining and finalizing Project Designs – This includes encouraging dialogue and information exchange, gathering input to understand areas of interest and concern, and considering and appropriately responding to the input provided. It also includes seeking input from the public on ways to mitigate or otherwise accommodate potential Project effects.

Ensure that all interested parties have the opportunity to make informed decisions about the Project – This includes providing timely and relevant information about the Project. For the purposes of the EA, the Ministry will ensure that the public has access to information about the environmental, economic, heritage, health and social conditions in the Project area, the potential Project effects, and proposed mitigation measures.

Meet EAO’s public consultation requirements for the EA – This includes tracking public input, and communicating to the public how public comments will be addressed in the EA. The Ministry’s Project website will provide information about the EA throughout the EA review process and will direct interested members of the public to EAO’s website to provide comments on the Project’s EA. In accordance with EAO’s requirements, the Ministry has maintained a tracking table in which the Ministry has responded to each individual public comment provided during the public comment period in the pre-Application phase of the EA process and will do the same for the Application Review phase. The Project has prepared a Consultation Report in accordance with EAO’s section 11 Order.

11.2.2 Public Consultation to Date

Since announcement of the Project in September 2012, the Ministry has been conducting technical analyses, raising awareness about the Project, engaging interested parties in dialogue, and responding to Project-related enquiries. As part of Project planning, the Ministry consulted widely, gaining insight from municipalities, Aboriginal Groups, Metro Vancouver, TransLink, the agricultural community, first responders, recreational groups, local businesses, local residents, cyclists, marine users, other stakeholders, and the public over a period of more than two years.

This section describes the consultation undertaken by the Ministry since fall 2012 up to the Pre-Application phase consultation. **Section 11.2.3** describes consultation undertaken as part of the pre-Application phase of the EA.

11.2.2.1 Ministry led Consultation Phases

The Ministry undertook three phases of Project consultation. Each phase included open houses complete with display boards, discussion guides and feedback forms, which provided participants with an opportunity to speak with Project staff. All consultation materials were made available online at masseytunnel.ca during and after each consultation event, and all events were advertised in local and regional newspapers, on the Project website, through the Project e-database (see “Project Office” section, below), and through media releases that resulted in broadcast and print news coverage. Following each consultation event or series of events, a Consultation Summary Report was prepared, documenting the input received.

Phase 1 Consultation: Understanding the Need (November/December 2012) sought input to gain a better understanding of current travel needs and community considerations for developing replacement options. This input was used to help develop a draft project scope and potential replacement scenarios. Results can be viewed in the Phase 1 Consultation Summary Report (<http://engage.gov.bc.ca/masseytunnel/files/2012/11/George-Massey-Tunnel-Phase-1-Consultation-Summary-Report3.pdf>).

Phase 2 Consultation: Exploring the Options (March/April 2013) sought input on five potential replacement scenarios which were developed in consideration of Phase 1 input. During this phase, participants indicated a preference for a new bridge along the existing Highway 99 corridor. Participants also expressed interest in transit, cyclist and pedestrian improvements as part of the Project, and interim improvements at the Tunnel while development for a new crossing continues. Results can be viewed in the Phase 2 Consultation Summary Report (<http://engage.gov.bc.ca/masseytunnel/files/2013/09/Phase-2-report-FINAL.pdf>).

Phase 3 Consultation: Project Definition (December 2015/January 2016) sought input on the Project Definition Report (<http://engage.gov.bc.ca/masseytunnel/files/2015/12/GMT-Project-Definition-Report-Dec-2015.pdf>) including the proposed Project scope, Project success measures, funding options, and traffic management during construction. This input assisted in finalizing the Application and also will be used to finalize the Project scope and cost estimate. Results can be viewed in the Phase 3 Consultation Summary Report (<http://engage.gov.bc.ca/masseytunnel/files/2016/04/Phase-3-Consultation-Summary-Report-March-2016.pdf>).

11.2.2.2 Project Office, Website and Telephone Information Line

A Project website (www.masseytunnel.ca) was established in November 2012 to provide information about the Project, including: historical information and reports; current Project status; Project-generated reports and information including consultation materials; answers to frequently asked questions; how to contact the Ministry; and how to subscribe to the Project e-database (see below). The Project work with the Ministry's social media team to incorporate Project updates into the Ministry's @TRANBC Twitter feed.

A Project-related electronic database (e-database) was established in November 2012, enabling people to sign up to receive e-mails about the Project. People can subscribe by completing the web-based form at www.masseytunnel.ca, emailing masseytunnel@gov.bc.ca, or phoning the Project Office (1-855-MASSEY). The database has more than 1,800 subscribers. Also established in November 2012, the Project information telephone line and e-mail address enable one-to-one correspondence and response to enquiries. Where possible, the Ministry responds to information requests within 48 hours.

A Project Office in Richmond was opened in January 2014. The Project Office has full-time community relations staff who provide Project information to the public as well as manage the website, the information telephone line, and the e-database. The office includes information display boards, access to the Project website, and fly-through animation of the Project corridor. To date (up to 15 May, 2016), more than 4,000 people have visited the Project office.

11.2.2.3 Stakeholder Outreach

The Ministry has engaged in a variety of additional outreach activities with the stakeholders identified in Section 11.1.1:

- **Presentations on request** to business and community groups. To date, the Ministry has made more than 100 presentations to organizations including:
 - Community and recreational clubs and organizations
 - Boards of Trade and Chambers of Commerce
 - Business clubs and associations
 - Professional organizations
 - Metro Vancouver planning, transportation, and engineering symposia

- **Meetings with key stakeholder groups** to gather input in support of developing conceptual designs for the new crossing. Since 2012, the Ministry has consulted extensively with:
 - Municipal, provincial and federal elected officials
 - Municipal, provincial and federal government staff
 - Provincial and federal agency staff
 - Aboriginal Groups
 - Stakeholder groups including agricultural organizations, business organizations, commercial and recreational marine users, community and resident groups, recreational groups, and first responders

The Ministry has participated in more than 85 meetings with City of Richmond staff and more than 85 meetings with Corporation of Delta staff, with whom the Ministry's Project team meets bi-weekly, and more than 30 meetings with Metro Vancouver staff.

11.2.2.4 Advertising and Media Relations

The Ministry maintains an ongoing and open dialogue with the media. Since November 2012, numerous stories have been published on the Project, including interviews with the Minister of Transportation and Infrastructure, the Executive Project Director, and other Project spokespersons. Highlights include:

- More than 750 directly related articles have been published in local and regional newspapers, primarily the Vancouver Sun, the Province, the Delta Optimist, South Delta Leader, Richmond News, and the Globe and Mail.
- Notification for each of the three phases of Project consultation to date (outside of the EA process) has been advertised in local and regional newspapers, which includes eight news releases, four information bulletins, and one public notice.

11.2.2.5 EA Public Consultation Phases

The B.C. EA process provides an integrated process for identifying, mitigating, and evaluating the potential for effects on environmental, economic, social, heritage, and health values that may occur during the life of a reviewable project. EAO led public comment periods, one held in the pre-Application phase, and another to be held in the Application review phase, and ongoing stakeholder consultation, seek to ensure that the interests and concerns of the public, Aboriginal Groups, stakeholders, and government agencies are considered. The following sections discuss EA related Public Consultation.

11.2.3 Pre-Application Phase Public Consultation

11.2.3.1 Public Comment Period

As part of the Pre-Application phase of the EA, the EAO held a public comment period from January 15, 2016 to February 15, 2016 that sought input on the Project Description and Key Areas of Study document for the Project

(http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39646.html).

Based on issues identified by the public, Aboriginal Groups, regulators, and local and regional governments during consultation to date, and the Ministry's experience on comparable projects in the Lower Mainland, the following key areas of study have been identified to support the assessment of potential environmental, economic, social, heritage, and health effects of the Project:

- River hydraulics and morphology
- Sediment quality and water quality
- Underwater noise
- Fish and fish habitat
- Marine mammals
- Vegetation
- Amphibians
- Terrestrial wildlife
- Traffic*
- Land and Water Use, *including marine use, land use and agricultural use*
- Visual quality
- Air quality
- Atmospheric noise
- Human health
- Heritage resources

*Traffic is not listed as a key area of study in the Project Description and Key Areas of Study document. As a result of interest from the public, Project related changes in traffic during construction and operation have been assessed as part of the EA (see **Section 5.1**) and support the assessment of atmospheric noise, air quality, human health, land use, and terrestrial wildlife.

Availability of the Project Description and Key Areas of Study

The Project Description and Key Areas of Study document and information regarding the environmental assessment process were available at:

- EAO's website,
- The Project website (www.masseytunnel.ca)

- All Municipal Libraries in the City of Richmond
- All Municipal Libraries in the Corporation of Delta
- The Project Office in Richmond
- Public comment period open houses

Public Notification

To inform interested individuals and the public, and to comply with EAO advertising requirements, the Ministry undertook the following notification program:

Advertising in regional and local papers, including:

- Vancouver Sun
- The Province
- The Richmond News
- The Delta Optimist
- The Leader
- The Now
- Peace Arch News
- Ming Pao
- Sing Tao
- Indo Canadian Times

Online information updates including:

- EAO's website at www.eao.gov.bc.ca
- The Project website (www.masseytunnel.ca)
- Ministry's Twitter feed @TRANBC

Email notices to people who registered to receive Project updates through the Ministry's Project website.

Two media releases, which generated extensive print, online and broadcast news coverage.

11.2.3.2 Open Houses

Two open houses, led by EAO, were held in support of the 31-day public comment period:

Table 11.2-1 Open House Overview

| Community | Date/Time | Venue |
|-----------|---|--|
| Richmond | Tuesday, January 26, 2016 2:00 p.m. – 8:00 p.m. | Sandman Signature Hotel Vancouver Airport Round Room 10251 St. Edwards Drive, Richmond, BC |
| Delta | Wednesday, January 27, 2016 2:00 p.m. – 8:00 p.m. | Delta Town & Country Inn Ballroom 6005 Highway 17A, Delta, BC |

More than 750 people attended the open houses. Project and EAO staff and the Ministry’s technical experts were present to answer questions on the Project. Copies of the Project Description and Key Areas of Study document were available, and display boards summarizing the Project, and the key areas of study identified for the Project, were presented. The display boards used at the Open Houses are included as an Appendix to the Phase 3 Consultation Summary Report and the Public Consultation Report prepared for EAO. A summary of feedback from the Open Houses and other sources of input is presented in **Table 11.2-3** in **Section 11.3.2.5** below.

11.2.3.3 Comments Submitted to the BC Environmental Assessment Office

Comments from the public were submitted to BC EAO over the length of the public comment period from January 15, 2016 to February 15, 2016 and posted to EAO’s electronic Project Information Centre (ePIC) within seven days of the comment being received by EAO (http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39730.html).

Approximately 450 public submissions were sent to EAO. Comments received and responses provided are available on the EAO’s website.

(http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39730.html).

A summary of comments from these submissions, as well as other sources of input, is presented in **Table 11.2-3**.

11.2.3.4 Stakeholder Consultation

Consultation with stakeholders to discuss the Project, and obtain feedback on the Project scope and the scope of environmental review has been ongoing throughout the pre-Application phase. In addition to engaging in a variety of outreach activities with stakeholders, the Ministry maintained its Project Office, website, and Information Line as described in **Section 3.2. Table 11.2-2** provides a summary of stakeholder outreach activities (scheduled meetings and presentations) undertaken by the Ministry during the pre-Application phase, from the release of the issuance of the section 10 Order on December 16, 2015 through to May 15, 2016.

Table 11.2-2 Summary of Project Public and Stakeholder Engagement Activities

| Dates | Agency/Organization | Type | Description |
|---------------|----------------------------------|---------------------------------------|---|
| 2015-12-16 | Media | Presentation and Q&A | Project Definition Report Technical Briefing |
| 2015-12-16/17 | Project Stakeholders | Notification Call and Follow-up email | Notification of release Project Definition Report and start of Pre-Application Phase for EA with issuance of section 10 Order |
| 2015-12-18 | Greater Vancouver Board of Trade | Presentation and Q&A | Project Update- Phase 3 Consultation |
| 2016-01-05 | City of Richmond | Meeting | Project Update on Project Definition Report and EA Process |
| 2016-01-07/08 | Project Stakeholders | Notification Call and Follow-up email | Notification of start of public comment period for Pre-Application Phase or EA and upcoming Open Houses. |
| 2016-01-12 | Richmond Chamber of Commerce | Presentation and Q&A | Project Update- Phase 3 Consultation |
| 2016-01-12 | Local Cycling Community | Presentation and Q&A | Project Update- Phase 3 Consultation |
| 2016-01-13 | BC Trucking Association | Presentation and Q&A | Project Update- Phase 3 Consultation |

| Dates | Agency/Organization | Type | Description |
|------------|---|-----------------------|---|
| 2016-01-13 | City of Richmond Active Transportation Committee (regular meeting of Committee) | Presentation and Q&A | Project Update- Phase 3 Consultation |

11.2.3.5 Summary of Public Feedback and Proponent Responses

This section summarizes the public feedback received at the open houses, comments submitted to EAO, and feedback received through the Ministry’s stakeholder outreach during the Pre-Application period (up to May 15 2016). **Table 11.2-3** below lists the key themes of feedback received, the Ministry’s general response to the comment or concern, and how that comment or concern has been or is being addressed in the Application. A complete list of comments formally received regarding the Project Description and Key Areas of study document is available on the EAO’s website (http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_project_home_430.html).

Table 11.2-3 Key Areas of Interest for Public and Stakeholders

| Theme | Response | Action/Status | Applicable Mitigation |
|---|--|---|-----------------------|
| <p>Analysis of other options:</p> <ul style="list-style-type: none"> • How was the new bridge option selected? • Why were other options not selected? • What consultation was done? • Preference for other options | <p>The Ministry evaluated five potential options for replacing the Tunnel. Each scenario was evaluated based on transportation efficiency, safety, agriculture, environment, economic considerations, and social and community considerations.</p> <p>As identified in the Ministry’s Phase 2 Exploring the Options Consultation Discussion Guide (http://engage.gov.bc.ca/masseytunnel/files/2012/11/GMT-Phase-2-Discussion-Guide.pdf), the public and stakeholders were consulted on the five potential options. Respondents expressed a clear choice for moving forward with capacity improvements along the existing corridor, with preference for a new bridge. Twice as many people preferred a completely new bridge as compared with a new bridge/upgraded tunnel scenario and many people specifically commented that any option including the existing Tunnel would not meet the Project goals.</p> <p>Substantial technical analysis was also undertaken, confirming that a new bridge is also the best technical solution. The analysis is summarized in the Evaluation of Crossing Scenarios report and is available on the Project website (http://engage.gov.bc.ca/masseytunnel/files/2015/06/GMT-2014-March_Evaluation-of-Crossing-Scenarios.pdf).</p> <p>A new bridge built to modern day standards is the most logical and cost-effective solution. As compared with upgrading the Tunnel, the new bridge will reduce crashes, improve emergency response time, provide a safer facility in the event of an earthquake, provide new options for cyclists and pedestrians, improve transit and HOV travel, allow flexibility for future rapid transit, and provide an enhanced traveler experience.</p> <p>As compared with a new tunnel, the new bridge will minimize private property impacts and environmental effects as well as provide more environmental and agricultural benefits. A new bridge also provides best flexibility to provide transit, cycling, and pedestrian improvements on Highway 99, including provision for future rapid transit.</p> <p>A discussion on Alternatives for the Project, including how technical analysis and extensive public consultation led to the determination of the new bridge as the preferred alternative, will be included in the Application.</p> | <p>Section 1.4 of the Application discusses the alternatives for the Project and how the alternatives were assessed.</p> | <p>N/A</p> |

| Theme | Response | Action/Status | Applicable Mitigation |
|---|---|---|-----------------------|
| <p>Consultation with the public:</p> <ul style="list-style-type: none"> • Past consultation results • Process transparency | <p>The Ministry adopted a phased public consultation program to support Project planning and development. This included:</p> <ul style="list-style-type: none"> • Phase 1: Understanding the Need (November to December 2012) Focused on understanding the need and potential constraints to develop the project scope and design requirements. • Phase 2: Exploring the Options (March to April 2013) – Based on Phase 1 consultation results and preliminary technical work, Phase 2 sought input on the draft project scope and goals, five potential replacement scenarios, and the criteria to evaluate these options. • Phase 3: Project Definition Report (December 16, 2015 to January 28, 2016) Sought feedback on the Project scope and business case, including goals, design features, benefit and cost analysis, draft performance evaluation/success measures, and tolling. <p>More than 1,000 people and dozens of community groups and associations participated in each of these consultations. Summary reports for each Phase are available on the Project website.</p> <p>The Ministry also consulted widely to gain insight from municipalities, Aboriginal Groups, Metro Vancouver, TransLink, the agricultural community, first responders, recreational groups, local businesses, local residents, cyclists, marine users, and other stakeholders.</p> <p>Based on this consultation, the Ministry identified and considered a diverse range of environmental and social values to guide Project design and support the EA presented in the Project Description and Key Areas of Study document.</p> <p>Public consultation and feedback plays an important role throughout the EA process. The Ministry prepared a Public Consultation Plan (http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39675.html), to outline and guide public consultation activities during the Pre-Application and Application Phase of the EA and to satisfy the requirements for public consultation established by EAO in the section 11 Order. As required under the section 11 Order, the Ministry will provide public notice prior to the start of any formal public comment period, and will submit a Public Consultation Report with the submission of the Application for evaluation and at any other time specified by EAO.</p> <p>The Project entered the EA process on December 16, 2015. The Pre-Application Phase public comment period was held January 15 to February 15, 2016 and included two public open houses in Richmond and Delta. Pre-Application public consultation focused on receiving input on the Project Description and Key Areas of Study document, to further develop the scope of the EA. The Ministry responded to all public comments received during this period and the Ministry's responses are posted to EAO's website.</p> <p>Throughout the Application Review phase, the Ministry will continue to engage with the public and stakeholders, which will include but not be limited to, maintaining the Project Office, the Project website and the community relations program as described in the Public Consultation Plan. In addition, there will be a second public comment period of at least 45 days on the Application, which will be made publicly available upon EAO's acceptance of the Application.</p> <p>The Application will include a discussion on Public Consultation to date.</p> | <p>The section 11 Order, issued by EAO, describes the consultation requirements for the Project.</p> <p>Section 10 of the Application discusses public consultation undertaken for the Project to date.</p> <p>The Ministry continues to consult with the public on the Project to provide Project information and to understand and address concerns.</p> | <p>N/A</p> |

| Theme | Response | Action/Status | Applicable Mitigation |
|--|--|--|-----------------------|
| <p>Perception that the Project is being constructed to benefit the Port of Vancouver:</p> <ul style="list-style-type: none"> • Increased industrialization of the Fraser River • Port users should pay for a portion of the costs | <p>The Tunnel is B.C.'s worst traffic bottleneck. The new bridge will reduce congestion, improve travel time and reliability, improve safety, and provide new options for cyclists, pedestrians and transit users. It is anticipated that the Project will provide up to 30 minutes a day in time savings for rush hour commuters.</p> <p>Public and stakeholder feedback received over two phases of consultation prior to the start of the EA, existing conditions at the Tunnel, and growing traffic congestion, made it clear that road-based improvements at this crossing are a priority.</p> <p>The new bridge will be the same height above the water as the Alex Fraser Bridge. Removing the Tunnel will not appreciably increase the size of vessels using the Fraser River South Arm channel, as the top of the Tunnel is level with the bottom of the River. Tunnel elevations relative to the river bottom will be provided in the Application. Other factors, including the Metro Vancouver water main downstream of the Tunnel, other utility crossings upstream of the Tunnel including Metro Vancouver water and sewer lines and Fortis BC gas line infrastructure, and the width of the river, limit the size of vessels that can navigate the river.</p> <p>The Province intends to fund the Project at least in part through user tolls. Consistent with Provincial Tolling Guidelines (http://www2.gov.bc.ca/assets/gov/driving-and-transportation/reports-and-reference/reports-and-studies/planning-strategy-economy/mot_guidelines_for_tolling.pdf), tolling recognizes that those directly benefiting from the new infrastructure in terms of time savings and reliability should help pay for the Project. The Province is also seeking a contribution from the federal government.</p> <p>Port-related goods movers using the crossing to go to or from Deltaport will help pay for the Project through the tolls they pay to travel across the new bridge.</p> <p>The Project Description and Key Areas of Study document outlines the Project rationale and describes the benefits it will provide. These details will be included in the Application.</p> | <p>Section 1.1 of the Application discusses the project rationale and Project components.</p> <p>Section 1.1 of the Application discusses Project costs and tolling as a funding source.</p> <p>Section 5.2 of the Application discusses navigation and marine use.</p> | <p>N/A</p> |

| Theme | Response | Action/Status | Applicable Mitigation |
|---|---|--|--|
| <p>Concern about potential agricultural impacts:</p> <ul style="list-style-type: none"> • Rationale for anticipated “net gain” in agricultural land • Concern about loss of ALR • Impacts on farm access • Increased food costs • Food security concerns • Impacts to the salt wedge | <p>The Ministry recognizes the importance of agriculture and minimizing impacts to agricultural land has been a key goal since the onset of the Project and was one of the key factors in determining a new bridge as the preferred crossing scenario. Agricultural land impacts and access to and from agricultural areas were presented as draft criteria for evaluating the potential crossing scenarios in the Phase 2 Exploring the Options Consultation Discussion Guide (https://engage.gov.bc.ca/masseytunnel/files/2012/11/GMT-Phase-2-Discussion-Guide.pdf). The Evaluation of Crossing Scenarios (https://engage.gov.bc.ca/masseytunnel/files/2015/06/GMT-2014-March_Evaluation-of-Crossing-Scenarios.pdf) presents the evaluation of the draft criteria for each of the scenarios which found the new bridge scenario was preferable to all other scenarios in improving the connectivity between agricultural areas on either side of the corridor, while also minimizing the agricultural land impact as compared to most other solutions.</p> <p>Agricultural use is identified in the Project Description and Key Areas of Study as an important value to be considered in as part of the Project development and potential Project related effects to agricultural use will be assessed as part of the environmental assessment. Studies have been completed with regard to the salt wedge in the river. Details will be provided in the Agriculture and River Hydraulics and River Morphology sections of the Application.</p> <p>The Ministry has been working with Agricultural Land Commission staff, municipalities, the farming community, and individual farmers for the past three years in order to identify strategies that maximize benefits to agriculture. Based on the current Project design, the Ministry anticipates a net gain in agricultural land in Delta and Richmond primarily because of the smaller design footprint for replacement interchanges, particularly at Steveston Highway.</p> <p>Additionally, the Project will improve travel times and access between farms on both sides of Highway 99, improve drainage along Highway 99 which will also benefit farming, and provide wider shoulders and higher underpasses to make it easier to move farm equipment. The Application will assess potential adverse effects on agricultural use and identify mitigation measures and strategies for achieving a net benefit to agricultural use.</p> <p>The Ministry is required to obtain approval under the <i>Agricultural Land Commission Act</i> prior to starting construction.</p> | <p>Section 5.4 of the Application discusses potential Project related effects to Agricultural Use. Salinity and the salt wedge is discussed in the Agriculture Use (b) and River Hydraulics and River Morphology (Section 4.1) of the Application.</p> | <p>Measures for avoidance of effects to agricultural use integrated into Project design include accommodating Project components and activities within the Highway 99 ROW and incorporating drainage works and structures that meet standards for agricultural areas and purposes.</p> <p>An Agricultural Management Plan will be developed for construction and will describe standard best practices and Project-specific mitigation measures to prevent or minimize potential effects on drainage, water quality and irrigation, farm infrastructure and operations, and soil conservation, storage, and reclamation.</p> <p>Enhancement and offsetting measures will also be applied.</p> <p>A net benefit to agricultural use is anticipated.</p> |
| <p>Concern about increased congestion at Oak Street Bridge and other Fraser River North Arm crossings:</p> <ul style="list-style-type: none"> • Project will move the queue further north • Project will generate increased traffic • Oak Street Bridge is already congested | <p>The Tunnel is the worst traffic bottleneck in B.C. The new bridge will alleviate the current queues experienced at the Tunnel.</p> <p>The Project is not expected to result in any appreciable change in queues at the Oak Street and Knight Street bridges. Analysis showing that the majority of traffic using the Tunnel (60 per cent) is destined to or from Richmond is presented in the Traffic Data Overview Report (http://engage.gov.bc.ca/masseytunnel/files/2015/12/Traffic-Data-Overview-2015.pdf). In fact, traffic volumes over the Oak Street Bridge have declined over the past five years and the City of Vancouver has indicated similar patterns at the Knight Street Bridge.</p> <p>Local roads will benefit from the new Steveston Highway and Westminster Highway interchanges in Richmond and new Highway 17A interchange in Delta as well as from reduced congestion at the new bridge.</p> <p>Project related changes in traffic will be assessed as part of the environmental assessment. The assessment of potential project-related changes in traffic, during construction and operation, will support the assessment of noise, air quality, human health, land use, and terrestrial wildlife. While the Application will present information on future trends in traffic at other Fraser River crossings, changes to the (existing) Highway 99 corridor have been determined to have a negligible influence on traffic conditions at other crossings in the future. As such, future changes in traffic at other crossings are not assessed as a potential effect of the Project but will be discussed.</p> | <p>The Project will improve performance of the Highway 99 corridor with respect to safety, travel time, reliability, and mode share.</p> <p>Section 5.1 of the Application discusses potential Project related changes to traffic, and includes a discussion on Oak Street Bridge traffic trends.</p> | <p>The Project will incorporate components consistent with the Ministry’s approach to Intelligent Transportation Systems to better manage and operate the corridor.</p> |

| Theme | Response | Action/Status | Applicable Mitigation |
|---|--|---|--|
| <p>Traffic during construction:</p> <ul style="list-style-type: none"> • Concern over how traffic through the corridor will be maintained • Concern over how marine traffic will be maintained | <p>The Ministry will work to ensure that road and marine traffic continues to move while the new bridge is under construction and will implement a Traffic Management Plan and a Marine Access Management Plan. Key mitigation within these plans includes communication with users of the corridor and the navigation channel. Traffic is assessed in Section 5.1 and Marine Use is assessed in Section 5.2 of the Application.</p> | <p>Section 12 of the Application discusses the requirement of a Construction Traffic Management Plan and a Marine Access Management Plan to be developed prior to construction.</p> | <p>A Construction Traffic Management Plan will be developed to identify and address traffic management risks and approaches for managing traffic and communication with stakeholders and the public during the construction period. A Marine Access Management Plan will be developed to minimize potential construction-related access effects on marine users. The plan will outline communications protocols to establish and advise of instream construction activities, including periods of vessel restrictions.</p> |
| <p>Preference for transit:</p> <ul style="list-style-type: none"> • Rapid transit in lieu of project • Transit generally, instead of project | <p>A new bridge was determined to be preferable in serving the needs of all user groups, including transit users, given the local, regional, provincial and national importance of Highway 99, the variable trip purposes on this corridor (goods movement, commuter, special generators etc.), vehicle requirements, origins and destinations of existing traffic; and planned future population and employment growth. The Evaluation of Crossing Scenarios (http://engage.gov.bc.ca/masseytunnel/files/2015/06/GMT-2014-March_Evaluation-of-Crossing-Scenarios.pdf) provides further background information on the preliminary analysis on alternatives considered to the Project.</p> <p>The Ministry worked with TransLink and area municipalities, including the City of Richmond, Corporation of Delta, and Metro Vancouver, to identify the improvements that could be incorporated into the Project to provide needed capacity improvements while also further encouraging transit, car-pooling, walking and cycling as alternatives to single occupancy vehicles on this corridor.</p> <p>The Ministry recognizes that this route is the busiest transit route of all the Fraser River road crossings, carrying more than 10,000 transit users daily, and has reflected this in the substantial transit improvements that have been incorporated in the Project scope. Improvements for transit on opening day include dedicated transit/ HOV lanes within the median for 24 km in each direction, integrated transit stops within the Steveston and Highway 17A interchanges and a dedicated transit ramp at Bridgeport Road enabling direct transit access to and from the Canada Line at Bridgeport Station. These measures will make transit more convenient and improve the reliability of transit travel times. A pedestrian and cycling pathway on the bridge with connections to the existing trail and cycling network in Richmond and Delta will allow cyclists and pedestrians to freely cross the Fraser River at this location. In addition, the new bridge will be built to accommodate potential future rapid transit.</p> | <p>Section 1.1 of the Application discusses the Project components, and will include a discussion on transit infrastructure for the Project.</p> <p>The Ministry continues to consult with TransLink, local governments and other stakeholders on the incorporation of transit into the Project scope.</p> <p>During operation, the Project will support provincial and regional strategies to encourage mode shift to transit and carpooling by providing continuous, dedicated transit/HOV lanes in both directions along Highway 99 between Surrey and Vancouver.</p> | <p>N/A</p> |

| Theme | Response | Action/Status | Applicable Mitigation |
|--|---|--|--|
| <p>Desire for greenhouse gas emissions reduction:</p> <ul style="list-style-type: none"> Federal and provincial targets Concern about increased traffic Suggestions that better options are available to reduce GHGs | <p>Greenhouse gas (GHG) emissions are discussed in Section 4.9 Air Quality of the Application. The Project is expected to help decrease future greenhouse gas emissions as compared with maintaining the existing Tunnel, supporting provincial and federal GHG reduction targets. This is due to reduced congestion-related idling as well as the effect of travel-demand management measures that promote transit, cycling and walking as alternatives to the single-occupant vehicle, discouraging growth in vehicle traffic over time.</p> <p>The findings of the Traffic assessment (Section 5.1) have been used to inform the assessment of air quality.</p> | <p>Section 4.9 of the Application discusses Air Quality. This section includes a discussion on Greenhouse Gas emissions.</p> | <p>The 2031 scenario with the Project shows an improvement in air quality compared to existing conditions.</p> |
| <p>Project funding:</p> <ul style="list-style-type: none"> Rationale for toll framework as proposed Equity concerns Suggestions to toll all bridges Suggestion that port/marine users should pay for the bridge | <p>The Province intends to fund the Project, at least in part, through user tolls. Consistent with Provincial Tolling Guidelines (http://engage.gov.bc.ca/masseytunnel/files/2015/06/GMT-2014-March_Evaluation-of-Crossing-Scenarios.pdf), tolling recognizes that those directly benefiting from the new infrastructure in terms of time savings and reliability should help pay for the Project. Tolling also ensures that the needed improvements can proceed now, without taking funding away from health care and education and without having to wait for years in the future when improvements will be even more overdue.</p> <p>Tolling is aligned with Metro Vancouver's Regional Growth Strategy's vision of compact communities, shorter travel distances and less vehicle traffic by encouraging transit and car-pooling and limiting traffic growth over time. This will result in a reduction in overall daily traffic levels, reducing GHG emissions.</p> <p>Phase 3 Consultation, held from December 2015, to January 2016 on the Ministry's Project Definition Report sought public feedback on tolling as a funding source. Results of this phase of consultation (http://engage.gov.bc.ca/masseytunnel/files/2016/04/Phase-3-Consultation-Summary-Report-March-2016.pdf) indicate that most participants supported tolling as a funding mechanism, although many participants suggested that tolling should be applied in the context of a regional tolling policy.</p> <p>It is anticipated that discussions about regional tolling will continue for some time and encompass a broad range of considerations. Any changes to the Provincial Tolling Guidelines may affect additional crossings and would be considered in advance of the anticipated start of tolling the new bridge, scheduled to open in 2022. The Province will continue discussions with the federal government to explore a funding partnership and confirm Project funding plans.</p> | <p>Section 1.1 of the Application includes a discussion on tolls in the context of Project financing.</p> <p>The Province will continue discussions with the federal government to explore a funding partnership and confirm Project funding plans.</p> | <p>N/A</p> |
| <p>Project size</p> <ul style="list-style-type: none"> Why 10 lanes? Recommendations for fewer lanes | <p>The assessment undertaken by the Ministry to confirm the appropriate number of lanes for the replacement bridge considered current traffic data, forecast volumes, safety, and other factors. As outlined in the Traffic Data Overview Report (http://engage.gov.bc.ca/masseytunnel/files/2015/12/Traffic-Data-Overview-2015.pdf) the Ministry's analysis confirmed a 10 lane bridge: results in greater safety benefits; provides room for trucks and other slower-moving traffic; facilitates the large volume of traffic entering and exiting the highway at the interchanges on either side of the crossing; allows for continuous dedicated median transit/ HOV lanes between Highway 91 in Delta and Bridgeport Road in Richmond, accommodates potential future rapid transit and; provides the capacity to handle future population and employment growth. An eight lane bridge would result in congestion on opening day, and therefore would not achieve one of the Project's primary objectives.</p> <p>As outlined in the Project's Business Case (http://engage.gov.bc.ca/masseytunnel/files/2015/12/Business-Case-Oct-2015.pdf), and the Evaluation of Crossing Scenarios (http://engage.gov.bc.ca/masseytunnel/files/2015/06/GMT-2014-March_Evaluation-of-Crossing-Scenarios.pdf), analysis confirmed that a 10-lane bridge results in greater safety benefits, with a projected 35 per cent reduction in collisions relative to the average annual collisions at the Tunnel and adjacent infrastructure.</p> | <p>Section 1.1 of the Application discusses the Project components and Section 1.4 of the Application discusses the rationale for having 10 lanes.</p> | <p>N/A</p> |

| Theme | Response | Action/Status | Applicable Mitigation |
|--|--|--|--|
| <p>Traffic diversion effects of tolling</p> <ul style="list-style-type: none"> • What impact will tolling the new bridge have on the Alex Fraser Bridge, Highway 91 and connecting routes? • Why not just toll the existing crossing to reduce traffic and the need for a new bridge? | <p>Traffic forecasts for the Project have been developed based on a program of in-depth research, data collection and analysis including consideration of the Regional Growth Strategy and Regional Transportation Model projections. Traffic volumes and patterns at the new Port Mann Bridge have also been evaluated in developing traffic forecasts for the Project.</p> <p>This work shows that during rush hours, traffic volumes on the new bridge likely will increase as some people switch from the congested Alex Fraser Bridge to the new bridge to take advantage of the time savings and increased reliability. That is the experience from other tolled crossings including the Port Mann Bridge as outlined in the Traffic Data Overview Report (http://engage.gov.bc.ca/masseytunnel/files/2015/12/Traffic-Data-Overview-2015.pdf).</p> <p>Outside of rush hours, the Ministry anticipates that some people will divert from the new bridge to the Alex Fraser Bridge to avoid paying the toll, while others will use it at all times of the day because of the convenience. This could lead to a reduction in volumes on evenings and weekends on the new bridge.</p> <p>Tolling the existing Tunnel without improvements may lead to some reduction in traffic, but does not meet current tolling guidelines, would put extreme pressure on the already congested Alex Fraser Bridge, and would not serve the broader regional and provincial needs to move goods and people.</p> <p>The Application will assess the potential Project related changes in traffic, and will include a discussion on potential effects related to tolling.</p> | <p>Section 5.1 of the Application discusses the potential Project related effects on traffic and includes a discussion on the potential effects of tolling.</p> <p>Section 1.1 of the Application includes a discussion on tolls in the context of Project financing.</p> | <p>Tolling will assist in managing traffic congestion, reduce future growth in traffic; and emissions; and support more favourable mode-share choices.</p> |
| <p>Risk of urban sprawl:</p> <ul style="list-style-type: none"> • Concern that the Project will encourage more car-based travel • Concern that the Project will change regional development patterns | <p>The Project aligns with regional and local land use plans including population and employment projections contained in Metro Vancouver's Regional Growth Strategy: Metro 2040.</p> <p>As communities grow, the need for travel grows. This includes travel for goods and services, much of which cannot be done via transit.</p> <p>The Project will reduce congestion, improve travel time and reliability, improve transit service, provide new alternatives for cycling and walking, provide safe alternatives for slower moving traffic, help improve travel time and reliability for Highway 99 Rapid Bus service, and pave the way for future rapid transit as demand grows. Most of these would not be possible if the Tunnel is not replaced.</p> <p>Land use is assessed in Section 5.3 of the Application. The assessment of land use describes how the Project aligns with and supports the implementation of regional and local land use plans, and population and employment projections identified in such plans. The assessment of traffic, and potential project related changes in traffic supported the assessment of land use.</p> | <p>Section 5.3 of the Application discusses how the Project aligns with local, provincial, and regional land use plans and designations, and will assess potential Project related changes to land use.</p> | <p>The Project supports overall regional growth trends under the land use plan set out in Metro Vancouver's Regional Growth Strategy</p> |
| <p>Impacts to the Fraser River and species:</p> <ul style="list-style-type: none"> • Potential effects on salmon • Potential effects on whales • Potential effects on birds • Potential effects on other species generally | <p>The Ministry recognizes that the Fraser River is a very important ecological area for fish and wildlife species, including salmon, sturgeon, eulachon, marine mammals, and migratory birds. The Fraser River and associated fish and wildlife habitat will be discussed as part of the following components: Fish and Fish Habitat, Sediment and Water Quality, Underwater Noise, River Hydraulics and Morphology, Marine Mammals, Marine Use and Terrestrial Wildlife (including birds).</p> | <p>The following sections of the Application discuss the Fraser River and associated fish and wildlife habitat:</p> <ul style="list-style-type: none"> • Section 4.2 Water Quality • Section 4.4 Fish and Fish Habitat • Section 4.6 Marine Mammals • Section 4.8 Terrestrial Wildlife | <p>Measures to avoid, reduce, or mitigate effects to these components are discussed in each individual section.</p> |

| Theme | Response | Action/Status | Applicable Mitigation |
|--|--|--|---|
| <p>Options for non-single occupant vehicles:</p> <ul style="list-style-type: none"> • HOV lanes • Bike/pedestrian pathway • Bus lanes • Transit stops | <p>The Project scope includes substantial measures to promote transit, car-pooling, walking and cycling as alternatives to single occupant vehicles. Improvements on opening day include dedicated transit/ HOV lanes within the median for 24 km in each direction, integrated transit stops within the Steveston and Highway 17A interchanges and a dedicated transit ramp at Bridgeport Road enabling direct transit access to and from the Canada Line at Bridgeport Station. These measures will make transit more convenient and improve the reliability of transit travel times.</p> <p>Multi-use pathways on the new bridge will provide new and enhanced opportunities for cyclists and pedestrians, as well as enhanced connections to community trails and cycling routes for interchange and overpass reconstructions.</p> <p>The Ministry consulted with TransLink, local communities and cycling stakeholders and has initiated a GMT Cycling Working Group to further engage with these groups in finalizing cycling plans.</p> | <p>Section 1.1 of the Application discusses the Project components, and will include a discussion on transit infrastructure for the Project.</p> <p>The Ministry continues to consult with TransLink, local governments and other stakeholders, including cyclists on the incorporation of transit and cycling infrastructure into the Project scope.</p> | <p>The Project was developed to help mitigate current and anticipated traffic challenges that are resulting in adverse effects on environmental, economic, social, and health values.</p> |
| <p>Noise</p> <ul style="list-style-type: none"> • Noise during construction • Changes in noise related to changes in traffic | <p>An effects assessment for noise, both during construction and Project operation is included in Section 4.10 Atmospheric Noise the Application. The parameters of the assessment for noise study are based on the anticipated Project construction activities, and traffic-related noise during operation.</p> <p>The assessment of community noise impacts follows the British Columbia Ministry of Transportation and Infrastructure, Policy for assessing and mitigating noise impacts from new and upgraded numbered highways, April 2014 (http://www.th.gov.bc.ca/publications/eng_publications/environment/references/MoTI_Noise_Policy_April_23_2014.pdf).</p> | <p>Section 4.10 of the Application discusses Atmospheric Noise.</p> | <p>A Noise Management Plan will be developed as part of the Construction Environmental Management Plan and will describe standard best practices to be implemented to minimize temporary, unavoidable construction-related noise.</p> |
| <p>Impacts to Deas Island Regional Park:</p> <ul style="list-style-type: none"> • Park experience • Access to the Park • Habitat values of the Park | <p>The Project presents an opportunity to create environmental and recreational improvements on the Fraser River, and within Deas Island Regional Park and Deas Slough. The new bridge will allow for connection of Deas Island Regional Park, which is currently separated by Highway 99 and the Tunnel. This will provide opportunities for improved access to and within the Park. Access to the Park will be maintained, during and post construction.</p> <p>Environmental opportunities include re-alignment of Green Slough and the creation of marsh habitat to support fish and wildlife.</p> | <p>Section 5.3 of the Application discusses Deas Island Regional Park.</p> <p>Section 4.4 of the Application discusses enhancement opportunities associated with Green Slough.</p> <p>The Ministry will continue to work with Metro Vancouver Parks regarding the enhancements associated with Deas Island Regional Park.</p> | <p>The Project is being built within the existing Highway 99 ROW (i.e., an already disturbed and developed corridor).</p> <p>Enhancement opportunities associated with land use, fish, and vegetation/ecosystems are being explored and are presented in the Application.</p> |

11.2.4 Future Consultation

Throughout the Application Review stage, the Ministry will continue to engage with the public and stakeholders. This will include, but not be limited to maintenance of the Project website, Project Office, and community relations program as described in **Section 11.2.2**.

The Application Review will include a public comment period. Activities related to the public comment period will be undertaken in a similar format as during the pre-Application phase public comment period. The proposed format for this consultation period is outlined in the Public Consultation Plan

(http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_430_39675.html).

If an EAC is awarded, the Ministry will continue to consult and engage with stakeholders and the public as the Project moves into subsequent Project phases (i.e., construction and operation). Consultation and engagement activities may include but are not limited to:

- Providing updates on the Project website and to the Project database and responding to public enquiries that arise from these updates.
- Presentations to community groups.
- Consultation with property owners and community groups.
- Surveys and consultations to measure project success against performance measures noted on page 30 of the Project Definition Report
- Development and implementation of construction environmental management plans.

Table 11.2-4 Public Consultation Schedule Summary

| Activity | Responsibility | Anticipated Timing |
|---|-----------------------|-------------------------------|
| Ongoing public and stakeholder engagement | | |
| All phases | Ministry | Nov 2012-Dec 2022 |
| Initial Engagement – Project conception and planning | | |
| Phase 1 consultation | Ministry | Nov/Dec 2012 |
| Phase 2 consultation | Ministry | Mar/April 2013 |
| Phase 3 consultation | Ministry | Dec 2015/Jan 2016 |
| Pre-Application Phase – issuance of section 10 Order to Application submission | | |
| Notifications for public open houses and public comment period on Project Description and Key Areas of Study document | Ministry/EAO | Jan 2016 |
| Public comment period on Project Description and Key Areas of Study document, including public open houses | Ministry/EAO | Jan 15-Feb15, 2016 |
| Ministry responses to public comments on Project Description and Key Areas of Study document including Public Consultation Report | Ministry | Feb 15 – March 2016 |
| Technical Working Group Meetings | EAO/Ministry | 21 Jan 2016 10 Mar 2016 |
| Application Review Phase - Application submission date to end of the (up to) 180-day Application Review stage (current stage). | | |
| Notifications for public open houses and public comment period on Application for EAC | Ministry/EAO | Summer 2016 |
| Public comment period on EAC Application, including public open houses | Ministry/EAO | Summer 2016 |
| Ministry responses to public comments on EAC application | Ministry | Summer 2016 |
| Public consultation report on Application Review phase | Ministry | Summer 2016 |
| Technical Working Group Meetings | EAO/Ministry | Dates to be determined by EAO |
| Post-EA - Post EAC issuance including for permitting, and throughout construction | | |
| On-going engagement | Ministry | ~ Winter 2016– Dec 2022 |

Part E – Management Plans and Follow-Up Programs

12.0 Management Plans

This section presents a summary of construction and operation environmental management plans (EMPs) that will be developed for works to be undertaken during construction (Construction EMP (CEMP)) and post-construction/operation (Operations EMP (OEMP)) of the Project. The requirements for Traffic Management, Marine Access Management, and Health and Safety Plans are also described. This section outlines the framework and content to be provided in the described plans, including associated monitoring and follow-up programs that will be developed and implemented.

12.1 Construction Environmental Management Plan

The objectives and components of the CEMP will be developed based on the recommended mitigation measures described in the Application, applicable legislation (licenses, permits, and approvals), BMP guidance documents, and the Ministry's *2012 Standard Specifications for Highway Construction: Section 165 Protection of the Environment* (B.C. MOTI 2012).

In addition to the components of the CEMP described within this section, it is expected that site-specific environmental work plans (EWPs) will be developed for specific Project construction components or (temporal or spatial) phases of construction, as appropriate. Site-specific work plans will be supplementary to the CEMP and will address the construction activities and environmental considerations applicable to a specific site or activity. Environmental work plans will be developed as required during Project construction and are therefore not discussed further in this section.

The objective of the CEMP is to provide guidance on actions and activities that will be carried out during Project construction. It will describe the environmental protection measures to be implemented during Project activities to address potential environmental effects of Project construction, and will comply with the environmental commitments described in **Part B – Assessment of Environmental, Economic, Social, Heritage, and Health Effects**, and summarized in **Section 14.2 Summary of Mitigation Measures**, as well as any provincial and federal licenses, permits and approvals required for the Project.

The CEMP will identify measures to reduce the risk of occurrence of incidents that could affect the environment, and minimize any effects that are unavoidable. The CEMP will provide a description of the roles and responsibilities of the environmental management team, the environmental mitigation and monitoring that is required for each of the sub-components within the CEMP, and will identify and describe environmentally sensitive zones within the Project alignment.

An environmental management team will be engaged, and will be comprised of qualified individuals who will develop and implement the CEMP. The environmental management team will have primary responsibility for confirming that the environmental management measures, controls, and specifications described within the CEMP are properly implemented. Mitigation and environmental management measures proposed for Project construction follow guidance documents and best management practices (BMPs) for land and highway development projects, and will be used during EMP preparation (see **Part B – Assessment of Environmental, Economic, Social, Heritage, and Health Effects**, and summarized in **Section 14.2 Summary of Mitigation Measures**), including but not limited to:

- *Best Management Practices for Pile Driving and Related Operations* (B.C. MPDCA 2003).
- *Develop with Care 2014: Environmental Guidelines for Urban and Rural Land Development in British Columbia* (B.C. MOE 2014).
- *Dredge Management Guidelines* (FREMP 2005).
- *Guidelines for Amphibian and Reptile Conservation during Urban and Rural Development in British Columbia* (B.C. FLNR 2014).
- *Guidelines for Raptor Conservation during Urban and Rural Land Development in British Columbia* (B.C. MOE 2013).
- *Land Development Guidelines for the Protection of Aquatic Habitat* (Chilibeck et al. 1993).
- *Measures to Avoid Causing Harm to Fish and Fish Habitat* (DFO 2013a).
- *Riparian Areas Regulation Implementation Guidebook* (B.C. MWLAP 2006).
- *Standards and Best Practices for Instream Works* (B.C. MWLAP 2004).

General BMPs that will be followed during construction will include:

- Maintenance of appropriate riparian setbacks along the Fraser River, Green Slough, Deas Slough, upland watercourses, and ditches.
- Storage and usage of deleterious substances more than 30 m away from a watercourse.
- Implementing appropriate vegetated buffers around raptor nests to mitigate sensory disturbance.
- Minimizing undertaking work during severe weather, which may increase the potential for erosion and sedimentation.
- Conducting works in a manner that will prevent the discharge or introduction of deleterious substances (including soil, sediment, or sediment-laden water, or turbid water) into the environment.

- Operation and storage of land- and marine-based equipment in a manner that will prevent damage to sensitive ecosystems and habitat.
- Utilizing existing linear and developed areas wherever possible to avoid unnecessary disturbance to undeveloped areas.
- Identifying and demarcating wildlife features within the Project alignment both on site plans and in the field.
- Avoiding clearing vegetation during the applicable nesting seasons for breeding birds (March 15 to July 31) and raptors (February 1 to August 14) whenever possible.
- When clearing may be required during the nesting season, conducting pre-clearing surveys and establish and maintain species-appropriate setbacks around active nests.
- Conducting instream works within the applicable least-risk timing windows whenever possible, unless otherwise approved.

Environmental monitoring will be conducted during construction of the Project and will have the key objective of ensuring construction activities are undertaken in accordance with the mitigation described within the Application and EAC, CEMP, and associated permits, licenses, and approvals. The CEMP will describe the frequency and scope of environmental monitoring and reporting that will be implemented throughout construction of the Project.

Implementation of the environmental monitoring program will be overseen by a qualified environmental professional and will be carried out during all construction activities that have the potential to result in adverse environmental effects. The environmental monitor will assess the implementation of the CEMP and any permits or approvals assigned to the Project, as well the effectiveness of the mitigation applied. The environmental monitor will be authorized to suspend any activity resulting in or potentially resulting in a breach of the CEMP or associated environmental permits, licences, and approvals. The CEMP will describe:

- Procedures to be undertaken to ensure work is conducted in accordance with the conditions of the EAC, applicable regulatory permits, licences, approvals, authorizations, and Ministry standards.
- A summary of the specific monitoring components to be undertaken.
- A schedule of when certain monitoring is to be conducted to fulfill the objectives of CEMP and its sub-components.
- Procedures and communications to be followed to track progress of action items and remediation requirements.
- Reporting requirements including format, timing, and distribution of environmental monitoring reports.

The CEMP will also describe training objectives and procedures to be used to maintain awareness of Project personnel regarding environmental considerations relevant to Project construction. Project personnel will be required to undertake environmental and safety orientation and awareness training prior to commencing onsite work. Training will include educating Project personnel on:

- Health and safety, and environmental roles and responsibilities of Project personnel.
- Project contacts, incident reporting procedures, and communication protocols.
- The objectives and purpose of the CEMP.
- Potential environmental issues that could occur during construction.
- Applicable regulatory compliance requirements and mitigation measures that are to be implemented during construction activities.
- Environmentally sensitive areas within the Project alignment.

The CEMP requires the preparation of a series of component plans, which will address more specific mitigation measures. The sub-component plans are expected to include:

- Air Quality and Dust Control Management Plan
- Agricultural Management Plan
- Archaeological and Heritage Resources Management Plan
- Contaminated Sites Management Plan
- Emergency Response and Spill Contingency Plan
- Erosion and Sediment Control Plan
- Fish and Fish Habitat Management Plan
- Marine Mammal Management Plan
- Noise Management Plan
- Terrestrial Vegetation and Wildlife Management Plan
- Waste Management Plan

12.1.1 Air Quality and Dust Control Management Plan

An Air Quality and Dust Control Management Plan will be developed, and will describe standard industry and best management practices to control and minimize fugitive dust and other airborne emissions associated with the operation of construction equipment, demolition and related decommissioning activities, stockpiling and handling of soils, and other construction activities.

This plan will describe the:

- Regulatory permits necessary for the operation of construction equipment or machinery capable of producing point-source emissions.
- Mitigation to be implemented during construction may include:
 - Procedures for the application of dust suppressants to construction areas and stockpiles to control fugitive dust and other airborne emissions.
 - Routine maintenance of vessels and vehicles.
 - Implementation of engine idling restrictions and selection of quieter vessels and vehicles when possible.
 - Managing speeds of construction-related vehicles.
- Air quality monitoring to be undertaken during Project construction activities with the potential to generate fugitive dust.

12.1.2 Agricultural Management Plan

An Agricultural Management Plan will be developed which will describe measures to avoid or mitigate potential impacts to agricultural land and activities during construction. The mitigation measures will be developed in parallel with planning the design and construction methodology for the Project, and shared with appropriate regulatory agencies and farm organizations prior to being finalized. Mitigation will be developed to minimize potential construction-related impacts to agricultural operations due to delays or detours during construction, changes in utilities or drainage/irrigation, and temporary usage of Agricultural Land Reserve land.

The plan will describe standard best practices and Project-specific mitigation measures to prevent or minimize potential adverse effects on drainage, water quality, and irrigation; farm infrastructure and operations; and soil conservation, storage, and reclamation. The plan will include:

- Procedures required for the reconstruction or upgrading of ditches in accordance with the B.C. *Agricultural Drainage Criteria* (B.C. MOAFF 2002).
- Consultation and communication program that will be undertaken to pro-actively inform farm operators potentially affected by Project-related activities during construction including potential changes in noise, drainage and irrigation, utilities, fencing, land use, and traffic.
- Procedures required to minimize the disruption of utility services (particularly power and natural gas supply) during construction, including if alternative power sources (e.g., generators or temporary power lines) may be required.

- Replacement requirements for any agricultural fences that may be damaged or moved as a result of the Project.
- Traffic management that will be implemented along major and secondary roads to facilitate the efficient movement of agricultural traffic throughout the communities and mitigate for temporary disruptions and increased traffic during construction.
- Mitigation to be implemented to reduce the potential for degradation of agricultural soils including, where possible:
 - Using non-arable areas for temporary laydowns and roads.
 - Reducing traffic in agricultural fields.
 - Developing a soil salvage, stockpile, and reclamation plan.
 - Implementing the spill response and contingency measures (as part of an Emergency Response and Spill Contingency Plan of the CEMP).
 - Implementing the erosion and sediment control measures, as part of the Erosion and Sediment Control Plan of the CEMP.
- A monitoring program that will be developed to evaluate the effectiveness of the mitigation implemented.

12.1.3 Archaeological and Heritage Resources Management Plan

An Archaeological and Heritage Resources Management Plan will be developed to address heritage site stewardship and protection relative to Project construction activities. The plan will be developed with guidance, where applicable, from the B.C. Archaeology Branch, as well as existing Ministry policies and procedures. It is not anticipated that previously undiscovered archaeological sites will be encountered during construction. Consistent with regulatory requirements and recognized best practices, the plan will describe:

- A chance-find procedure to be followed during construction in the event that a previously unknown heritage resource is encountered.
- A human remains protocol to be followed during construction in the event that human remains are encountered.
- Proper identification, reporting, and management of archaeological, heritage, and historical resources within the Project alignment.
- Roles and responsibilities of a professional archaeologist to ensure archaeological monitoring is conducted as required.

12.1.4 Contaminated Sites and Sediment Management Plan

A Contaminated Sites and Sediment Management Plan will be developed to guide the management of known or encountered contaminated sites within the Project area in compliance with the *Environmental Management Act*, S.B.C. 2003, c. 53, Contaminated Sites Regulation, B.C. Reg. 375/96, and relevant best practices and appropriate BMPs. It will also be developed to ensure that imported material or fill moved between Project locations or brought from off-site locations is clean and conforms to the criteria established in the *Environmental Management Act*, Contaminated Sites Regulation. The plan will:

- Describe procedures to be undertaken to ensure proper reporting and management of known or encountered contaminated sites within the Project alignment.
- Identify criteria and describe procedures for site characterization of excavated riverbed material in preparation for Tunnel removal.
- Outline regulatory and permitting requirements for upland disposal of excavated material.
- Identify procedures for selection of upland sites for disposal of excavated material in conformance with the *Environmental Management Act*, *Contaminated Sites Regulation*, and applicable soil deposition permits.

12.1.5 Emergency Response and Spill Contingency Plan

An Emergency Response and Spill Contingency Plan will be developed and will describe how construction personnel will prevent, prepare for, respond to, and clean up spills. The plan will include a description of spill prevention measures and clean up equipment that will be required onsite, as well as the procedures (containment, clean-up, and disposal) to be undertaken for marine and terrestrial environments.

The plan will describe the appropriate BMPs and procedures for preparing for and responding to Project-related emergencies, such as:

- Spills of toxic or hazardous materials (e.g., hydrocarbon fuels, lubricants, or concrete) into terrestrial and aquatic habitat, including environmentally sensitive sites.
- Structural failure of a culvert, ditch, detention pond, or sediment containment facility resulting in localized flooding, erosion, sedimentation, or discharge of deleterious materials to the environment.
- Inappropriate operation of machinery or equipment that leads to the disturbance of environmentally sensitive habitat or impacts to wildlife.
- Accidents involving collisions between vehicles moving through or around construction areas at the Project site.
- Marine vessel grounding and collision with other vessels, marine facilities, or marine mammals.

The plan will describe the following key components:

- Site security and personnel safety.
- Pre-emergency planning and risk identification.
- Emergency organization and training, as well as emergency personnel responsibilities (including contact details, emergency telephone lines), and command structure.
- Emergency response, and evacuation procedures.
- Identification, storage, and management of potentially deleterious materials.
- Spill identification.
- Spill containment materials available onsite and how to use them.
- Specific spill reporting requirements in accordance with the Spill Reporting Regulation under the *BC Environmental Management Act*.
- Communication requirements, including a communications plan to inform applicable stakeholders of a spill.
- Site restoration and remediation requirements.
- Post-incident evaluation and follow up and preventative actions.

12.1.6 Erosion and Sediment Control Plan

An Erosion and Sediment Control Plan will be developed, and will describe standard BMPs, and mitigation measures that will be implemented to prevent or minimize adverse effects to water quality in upland ditches and the marine environment. The primary objective of the plan will be to ensure that, during Project construction, water from the site that is discharged into the receiving environment will meet suspended sediment requirements outlined in the Canadian Council of Ministers of the Environment (2002) and the B.C. (B.C. MOE 2006) water quality guidelines. Erosion prevention and sediment control measures that will be implemented during construction may include:

- Developing temporary drainage systems to receive, filter, and direct stormwater and runoff during construction.
- Installation of sediment control measures.
- Developing sediment settlement ponds, if required.
- Re-stabilization of vegetated areas that are cleared or disturbed during construction.
- Careful storage of waste material and soil to prevent possible entry into the aquatic environment.

The plan will describe:

- Measures to be applied to mitigate soil erosion and sediment transport to the receiving environment such as installing silt fences or other appropriate mitigation.
- Measures to control sediment-laden flows and prevent sediment-laden water from entering watercourses such as utilizing gravel filter dikes, sedimentation ponds, or other water quality management measures to be selected and implemented on a site-specific basis.
- Guidelines to be followed to mitigate erosion and sediment transport, such as:
 - Develop with Care: Environmental Guidelines for Urban and Rural Land Development in British Columbia (2014).
 - Standards and Best Practices for Instream Works (MWLAP 2004).
- Procedures for monitoring, maintenance, repair, or replacement of stormwater drainage and sediment control systems.
- Maintenance procedures for managing stockpiled material to minimize erosion or generation of fugitive dust.
- Measures to control the dispersion of re-suspended sediments during in-water activities with the potential to result in physical disturbance.
- Water quality monitoring to be undertaken during Project construction activities that have the potential to induce turbidity, including sampling locations and frequency, as well as federal and provincial water quality criteria to be used for the evaluation of water quality samples.
- Protocols to address and resolve issues in the event that water quality parameters exceed, or have the potential to exceed, federal and provincial guidelines.
- Incident reporting requirements and the approach to be undertaken in the event of a reportable release of sediment or sediment-laden water into a watercourse.
- Proper storage and disposal of construction waste, soil, or other potentially deleterious substances, to prevent entry to the aquatic environment.
- Applicable vegetated buffer areas to be applied on a site-specific basis.

12.1.7 Fish and Fish Habitat Management Plan

A Fish and Fish Habitat Management Plan will be developed to protect fish and fish habitat during construction. The objectives of the plan will be to protect aquatic, foreshore and riparian habitat by avoiding or minimizing impacts through Project design and construction methodology and the application of mitigation measures. The plan will comply with the *Fisheries Act*, and provincial standards and best practices, including the Ministry's 2012 *Standard Specifications for Highway Construction* (B.C. MOTI 2012), and the Ministry's *Environmental Best Practices for Highway Maintenance Activities* (B.C. MOTI 2010). The plan will be provided to applicable regulatory agencies for review prior to finalization.

The plan will as a minimum:

- Identify and classify fish habitat within the Project alignment.
- Describe protection zones to be delineated with fencing or other protection to minimize erosion or sedimentation including appropriate riparian setbacks on a site-specific basis.
- Describe regional least-risk timing windows to be applied during specific Project activities (e.g., Tunnel decommissioning, in-stream works in and around upland watercourses) that have the potential to cause adverse effects to fish and fish habitat.
- Describe watercourse isolation measures and fish salvage and relocation activities to be applied in the event that in-stream works in upland watercourses are to be undertaken outside least-risk timing windows (in consultation with FLRN and DFO).
- Describe ditch realignment and applicable riparian restoration guidelines (e.g., B.C. MELP 1996, B.C. MOE 2008b).
- Describe construction and post-construction fish and fish habitat monitoring requirements.

12.1.8 Marine Mammal Management Plan

A Marine Mammal Management Plan will be developed to reduce the potential for effects of the Project on marine mammals during construction. The plan will describe standard best practices and mitigation measures that will be implemented to minimize underwater noise generated during marine-based construction activities, and to mitigate the potential for physical injury to marine mammals. Mitigation and monitoring measures that will be described in the plan will include, but will not be limited to:

- Limited use of engines and propellers on stationary vessels, whenever possible.
- Maintaining consistent navigation courses and speeds.
- Conducting land-based pile driving whenever possible.
- Conducting activities with the potential to generate underwater noise as efficiently as possible.
- Avoiding unnecessary idling of marine-based equipment.
- Procedures to prevent direct or indirect discharge of deleterious substances (including soil, sediment, sediment laden or turbid water, or fuel, and oils) into the marine environment.
- Implementation of marine mammal monitoring during activities anticipated to generate underwater noise, including an underwater noise monitoring program.
- Underwater noise monitoring to be conducted during Project construction activities that have the potential to generate underwater sound levels that may exceed auditory thresholds that can cause physical injury to fish and marine mammals.

12.1.9 Noise Management Plan

A Noise Management Plan will be developed to describe measures that will be implemented to minimize community impacts to temporary, unavoidable construction-related noise. Noise abatement measures and timing of specific construction activities will be planned to limit disruption to sensitive receptors including adjacent residential communities, educational facilities, places of worship, recreational areas, and wildlife. Construction-related noise will be reduced by implementing best practices and measures to reduce noise created by machinery used during construction as much as possible.

The plan will describe mitigation to be implemented to reduce, wherever possible, noise generated by marine and land-based construction activities. The plan will describe:

- Equipment and activity restrictions to be implemented to minimize noise emissions.
- Site-specific construction schedules and activities.
- Procedures and best management practices to control construction noise emissions such as using mufflers on equipment and maintaining equipment in good working order.
- Developing and implementing a community relations/stakeholder communication program to inform potentially affected communities of construction schedules and activities that may create temporary increases in noise. Communication methods may include signage, a telephone line, web-based updates and communications, newspaper ads, or direct communication.
- Noise monitoring to be undertaken during Project construction activities with the potential to generate fugitive dust and increased noise.
- Developing and implementing a construction noise monitoring program to document community noise exposures and assess effectiveness of implemented mitigation measures.

12.1.10 Terrestrial Vegetation and Wildlife Management Plan

A Terrestrial Vegetation and Wildlife Management Plan will be developed to avoid or mitigate potential impacts to vegetation and wildlife species during Project construction. The plan will be developed in parallel with finalizing the design and construction methodology of the Project and will be provided to applicable regulatory agencies (such as the B.C. Ministry of Forests, Lands and Natural Resource Operations).

The plan will:

- Provide current information on the presence of environmentally sensitive areas within the Project alignment and any specific procedures that may be required within each sensitive area.
- Provide guidelines on minimizing Project disturbance, use of heavy machinery to avoid soil compaction, and duration of construction.
- Describe pre-construction requirements including permitting, nest survey protocols, timing windows, buffer zones, and wildlife salvage and translocation procedures that may be required.
- Procedures for managing and reporting on interactions with wildlife, including wildlife observations, and wildfire injury or mortality as a result of construction activities.
- Describe rehabilitation requirements that should be undertaken following unavoidable disturbance to terrestrial habitat.
- Describe measures to offset unavoidable habitat loss effects to terrestrial vegetation and wildlife.
- Describe during and post-construction monitoring requirements to confirm offsetting measures are functioning as intended.

Mitigation measures that will be implemented during construction will include procedures such as:

- Site preparation activities to be undertaken prior to commencement of construction, including:
 - Identification on site plans and demarcation in the field of wildlife habitat areas, including nests or wildlife trees.
 - Providing training and education on wildlife that could be expected to occur within the Project alignment.
- Appropriate storage and waste disposal procedures to reduce wildlife attraction.
- Appropriate mitigation for decommissioning of the Deas Slough Bridge to mitigate impacts to barn swallows.
- Appropriate measures to be undertaken for vegetation clearing activities including undertaking clearing within the least-risk timing window for breeding birds (approximately August 1 to March 14) and raptors (approximately August 15 to January 30).
- If works cannot be conducted within the appropriate timing windows, pre-clearing nest surveys will be undertaken by a qualified professional.
- Maintenance of appropriate disturbance buffer zones around active raptor nests.

- Invasive species management requirements to be implemented to mitigate the introduction, transport, and expansion of invasive plant species and noxious weeds to, within, and from the Project area, including:
 - Identification of invasive plants and noxious weeds known to be, or having the potential to be present within the Project alignment including species for which there is a requirement to control under the B.C. *Weed Control Act*, R.S.B.C. 1996, c. 487, as well as species that are listed by the Invasive Species Council of Metro Vancouver.
 - Appropriate monitoring and control methods.

12.1.11 Waste Management Plan

A Waste Management Plan will be developed and will describe the provisions for minimizing waste production, and appropriate methods for management of hazardous and non-hazardous material. The plan will describe the transport, recycling and disposal procedures that will be required to manage waste that is expected to be generated during construction activities. Waste materials produced during construction may include steel and concrete materials, sand and gravel, and organic materials generated from vegetation clearing. Waste management that will be described within the plan will include:

- Appropriate disposal procedures to manage construction materials, waste material, sediment and soil, or other materials or substances potentially deleterious to the marine or terrestrial environment.
- Appropriate management measures for managing material (such as garbage) that may attract wildlife.
- Disposal of solid waste at an appropriate disposal or recycling facility.
- Reusing and recycling materials whenever possible.

In the event that hazardous materials are encountered, they will be transported, handled, and disposed of in accordance with the *Environmental Management Act*, Hazardous Waste Regulation, B.C. Reg. 63/88. The plan will describe how construction debris will be managed to ensure compliance with the *Environmental Management Act* as well as the procedures for waste reduction, re-use and recycling, and appropriate waste disposal. Where construction activities will involve the handling, storage, and removal of hazardous waste, a description and quantity of the hazardous waste generated, stored, or removed will be recorded. Any hazardous wastes recovered from a spill will be disposed of at an appropriate off-site disposal facility.

12.2 Construction Traffic Management Plan

A Construction Traffic Management Plan will be developed to describe measures that will be applied to avoid or mitigate potential effects to traffic associated with Project construction. The plan will address land-based construction traffic, traffic control, and potential traffic hazards associated with construction of the Project. The plan will be prepared in accordance with applicable regulations and standards including the *BC Workers Compensation Act* and *Occupational Health and Safety Regulation*, and the Ministry of Transportation Traffic Control Manual for Work on Roadways (MOTI 1999).

Traffic will be managed to ensure construction, public, and emergency vehicles; cyclists; and pedestrians can pass through the Project area safely during the construction period. Traffic management will involve detour routes with appropriate signage, transition zones, and buffer areas. Traffic personnel will be located at key traffic control areas to guide traffic and to monitor the effectiveness of the traffic routes.

The Construction Traffic Management Plan will be shared with appropriate agencies and local governments prior to being finalized. The plan will:

- Identify how current information regarding construction activities, construction periods, and route options will be communicated to stakeholders, emergency responders, municipalities, and adjacent land users, such as through radio notices, signage, a website, a telephone line, and message boards.
- Describe communication requirements to share information regarding traffic management during Project construction, traffic control measures, traffic interruptions, restrictions, and re-routing scenarios.
- Include how access will be provided for emergency vehicles including access in the event of an incident or emergency both within and externally to the Project where emergency vehicle and response personnel require passage through the site.
- Identify key detours and traffic changes and schedules for such detours and changes.
- Describe the communication activities to be undertaken to provide information to the public regarding changes in traffic, including vehicular, pedestrian, cyclist, and recreational traffic.
- Describe the requirements for consultation with the agricultural community to facilitate efficient movement of agricultural traffic, goods, and services during construction.
- Describe the duties and responsibilities of traffic control personnel that will be involved in the development, implementation, and management of the Construction Traffic Management Plan.

12.3 Marine Access Management Plan

A Marine Access Management Plan will be developed that will outline the measures to be implemented to avoid or minimize potential Project-related effects on marine use during marine-based construction activities. The plan will address marine-based construction traffic, traffic control, and potential traffic hazards associated with the Project. Specific mitigation will be developed based on the final designs and confirmed construction approach for the marine-based construction components, including location of staging areas and navigation routes to and from the construction site.

The plan will be shared with marine stakeholders, including Aboriginal Groups, the Vancouver Fraser Port Authority, Canadian Coast Guard, Metro Vancouver, the City of Richmond, the Corporation of Delta, and other local marine users, construction contractors, and representatives of marine communications and traffic services. The plan will adhere to the requirements of Transport Canada's Navigation Protection Program, pursuant to the *Navigation Protection Act*, R.S.C., 1985, c. N-22, and will:

- Identify any marine-based staging areas that may be required during Project construction.
- Identify travel corridors for marine vessels and equipment into and within the Project alignment.
- Describe the anticipated construction schedule for marine-based activities.
- Identify priorities for the timing and location of marine access, and options for the alternative movement of vessels and boats.
- Describe any required navigational aids, markers, and signs that will be used to delineate construction areas.
- Detail local marine communications and emergency preparedness procedures, including but not limited to:
 - Marine stakeholder communication program to inform the marine community of construction and decommissioning activities that may interfere with navigation.
 - Establishment of an emergency telephone line that will be available to the marine community during new bridge construction and Tunnel decommissioning.
 - Issuance and posting of notices regarding construction schedule.
 - Processes and procedures to inform marine traffic (e.g., through signage, a website, a direct telephone line for information) of any in-river activities that may encroach the navigation channel and other areas frequented by marine users, construction phasing, work scheduling, location of in-river staging areas, and times and duration of temporary navigation channel closures.

12.4 Health and Safety Plan

A Health and Safety Plan will be developed in accordance with the *Workers Compensation Act* and appropriate regulations. Contractors will be required to develop a health and safety plan for applicable components of work prior to the start of construction.

The Project Health and Safety Plan will include but not be limited to:

- Identification of potential site hazards
- Mitigation procedures and protocols for working around construction sites
- Site location and local emergency and Project contact telephone numbers
- Description and map of emergency routes
- Safety equipment required
- Safety training requirements

12.5 Operation Environmental Management Plan

Following completion of Project construction, an OEMP will be developed. The plan will describe the post-construction environmental management measures and BMPs that will be in place. The OEMP will be developed to avoid or minimize the potential for adverse environmental effects that may occur during post-construction Project activities such as maintenance and rehabilitation and implementation of follow-up plans. The plan will describe:

- The objectives and scope of the OEMP.
- Environmental monitoring frequency and activities to be undertaken during routine Project operations and requirements to be undertaken during specific maintenance activities.
- Implementation of post-construction/follow-up monitoring program and reporting requirements.
- Emergency maintenance procedures.
- Emergency spill response containment and management procedures.
- Management of stormwater and surface water runoff and maintenance of stormwater management features and facilities.
- Road and structure maintenance procedures.
- Vegetation and Wildlife management plans.

- Fish and Fish Habitat management including a Fish Habitat Offsetting Plan, if required, which will comply with the Fisheries Act, and will be guided by Fisheries and Oceans Canada Fisheries *Productivity Investment Policy: A Proponent's Guide to Offsetting* (DFO 2013b). The plan will:
 - Identify on- or near-site offsetting opportunities and concepts.
 - Outline offsetting implementation methods.
 - Describe post-construction monitoring requirements to determine efficacy of fish habitat offsetting efforts.

13.0 Monitoring and Follow-up Programs

This section describes how the results of monitoring programs, described in **Section 12 Management Plans**, will be used to support Project-related reporting and follow up programs, including EAO compliance reporting. In addition, this section provides an overview of the reporting structure that will support the delivery of the conditions of the EAC including the roles of the Contractor and Ministry.

13.1 Monitoring and Reporting

All of the management plans identified in **Section 12**, which are part of the CEMP and/or OEMP, will have a monitoring component to support reporting to the Contractor, Ministry, and in some cases external parties including the EAO, regulatory agencies, and members of the Technical Working Group.

Monitoring of the implementation of management plans will be supported by the collection and analysis of information, including technical data as well as onsite conditions collected during site visits. Information collected to support monitoring of EMP implementation, will be used to confirm the effective implementation of mitigation measures and compliance with conditions of the EAC.

Data to be collected and the frequency of data collection, for specific VCs and ICs, will be management plan specific and described in the detailed EMPs to be developed by the Contractor.

In terms of reporting during the construction phase, environmental monitoring reports will be developed that will include:

- General Project status including completion of key milestones
- Summary of the results of environmental monitoring activities
- Environmental incidents that may have occurred in addition to how incidents were responded to or addressed
- Potential areas for corrective action where applicable

An environmental report for the Project will also be undertaken that summarizes overall implementation of Project EMPs and the status of implementation of conditions associated with the EAC. The frequency and duration of environmental monitoring and reporting following completion of construction will be confirmed during the review of the Application in consultation with the EAO.

13.2 Follow Up Program

Monitoring data will also be used to support the implementation of the Follow Up Program for the Project. The program focuses on the implementation of Follow Up Strategies for specific VCs and ICs as described in **Section 3.11** and presented in VC and IC sections where it has been determined that there is the potential for a residual effect following implementation of mitigation measures. Monitoring is an important aspect of follow up strategies and serves to:

- Evaluate accuracy of original effects predictions
- Evaluate the effectiveness of mitigation
- Support identification of additional or different mitigation where original effects prediction and/or effectiveness of mitigation were not as anticipated

The majority of the residual effects identified for the Project are temporary in nature and associated with the construction phase. Follow up strategies that have been identified apply to the post-construction/operations phase of the Project and are proposed for the following VCs and ICs:

- River hydraulics
- Fish and Fish Habitat
- Vegetation
- Terrestrial Wildlife
- Atmospheric Noise

13.3 Reporting structure

During delivery of the Project (i.e., construction and post-construction phases), implementation of conditions of environmental approvals, including but not limited to the EAC, will be the responsibility of the Contractor, except in scenarios where works are undertaken by the Ministry. The Contractor will lead the development and implementation of EMPs discussed in **Section 12** as well as meeting environmental reporting requirements associated with the EAC.

The Contractor's team will include an Environmental Manager that will oversee technical specialists with expertise in relevant areas (e.g., noise, air quality, water quality, fisheries etc.) that:

- Provides environmental technical advice and support to the Contractor in relevant areas
- Provides input into the final Project design and development of construction plans

- Develops and implements mitigation consistent with the conditions of the EAC and all other required environmental approvals
- Undertakes environmental monitoring and reporting
- Provides support to the Contractor in responding to environmental incidents

A detailed description of the specific environmental resources, and roles and responsibilities, within the Contractor's environmental team will be provided in the CEMP that will be finalized following award of the Concession contract.

During Project delivery, the Ministry will oversee the work of the Contractor to ensure compliance with contractual environmental requirements including the conditions of the EAC. The Ministry will be supported by environmental specialists that will assist in undertaking audits focused on delivery of environmental requirements.

13.4 EAO Compliance Monitoring

Compliance monitoring, led by EAO, is undertaken to ensure that the Proponent advances approved projects in a manner that is consistent with the conditions of the EAC. Compliance monitoring activities, led by EAO, include the review of reports submitted to the EAO in accordance with established compliance monitoring requirements as well as planned site visits to support compliance monitoring and verify information provided in written reports.

During construction, the Contractor will report on implementation of the CEMP and status of the Project commitments within a defined reporting schedule developed as part of the conditions of the EAC. In the event of an environmental incident, monitoring and follow-up reporting will be implemented as required.

During construction, the Ministry will submit reports on the status of compliance with the terms and conditions of the EAC at a frequency confirmed with EAO during the Application review. It is anticipated that the reporting period will commence at the issuance of the EAC.

Environmental monitoring during construction that will support EAO compliance monitoring is expected to include the following;

- Environmental monitoring reports providing results of monitoring of conditions of VCs/ICs (e.g., water quality, air quality, noise etc.)
- Summary reports to EAO on the status of Project construction and status of conditions associated with the EAC

- Compliance reports describing audits conducted by the Contractor(s), Ministry, and regulatory agencies, including findings and follow-up items
- Monitoring reports associated with environmental permits and approvals (such as a fisheries authorization), where applicable
- Reporting on accidents, malfunctions, or spills to appropriate agencies and authorities

Some limited environmental monitoring is anticipated to continue post-construction with such requirements to be confirmed by EAO and may include:

- Reports to EAO on the status of ongoing Project commitments if applicable
- Compliance reports describing audits conducted by the Ministry, Contractor, and regulatory agencies, including findings and follow-up items
- Reports on the effectiveness of applicable post-construction mitigation (e.g., noise mitigation; river hydraulics, fisheries offsetting sites, vegetation, and wildlife etc.)
- Monitoring reports associated with environmental permits and approvals (such as a fisheries authorization), if applicable

14.1 Summary of Residual Effects

A summary of the results of the assessment of potential Project-related effects on valued components (VCs) and intermediate components (ICs) presented in Part B of the Application is provided in a table format (**Table 14.1-1 – Summary of Assessment of Potential Project-related Effects**) in this section. An overview of the following is included in the table:

- Potential Project-related effects on each VC and IC
- Project phases/activities that the effects are associated with.
- Brief overview of mitigation strategies proposed to address potential effects
- Residual effects, i.e. effects remaining after implementation of mitigation measures
- Result of determination of significance of residual effects for each VC
- Cumulative effects, where applicable

Further detail on specific mitigation measures proposed to address potential Project-related effects on each VC and IC is provided in **Table 14.2 Summary of Mitigation Measures**.

Table 14.1-1 Summary of Assessment of Potential Project-related Residual Effects

| Potential Effect | Project Phase/Activity | Mitigation | Residual Effects | Significance ¹ | Cumulative Effect |
|---|---|--|---|---------------------------|---|
| River Hydraulics and River Morphology | | | | | |
| <ul style="list-style-type: none"> Increase in volume of suspended sediment in Fraser River South Arm during Tunnel decommissioning Change in riverbed associated with Tunnel removal, and potential for associated effects on the Lulu Island-Delta watermain | Construction <ul style="list-style-type: none"> Tunnel Decommissioning | <ul style="list-style-type: none"> Implementation of standard best management practices Engagement with Metro Vancouver, who owns the watermain Monitoring of riverbed during and post Tunnel removal Follow-up action, if required, to address effects on the watermain | <ul style="list-style-type: none"> Temporary, short-term increase in volume of suspended sediment during Tunnel removal Riverbed lowering between the Tunnel alignment and the Lulu Island-Delta water main for one to two years after Tunnel removal | N/A | No overlap or interaction of Project-related residual effects with effects of other project or activities is expected; thus, no cumulative effects are anticipated. |

14.2 Summary of Mitigation Measures

Table 14.2-1 provides a list of measures that were developed to avoid, minimize, or offset potential adverse effects of the Project on environmental, socio-economic, heritage, and health pillars as discussed in **Part B – Effects Assessment**.

Since the same mitigation measure may apply to more than one topic, the measure is fully described in the first section in which it appears, and is referenced by its number thereafter. Project design considerations or other measures that avoid or minimize potential Project-related effects, in addition to the mitigation measures included in **Table 14.2-1**, are discussed in the effects assessment of each valued component.

In the table, timing refers to when the mitigation measure will be finalized and implemented. Where permits or authorizations are attached to a mitigation measure, the associated legislation and regulatory agency responsible for issuing the permit or authorization are identified in the table under columns titled Legal Requirement and Responsible Agency, respectively.

Table 14.2-1 Proposed Mitigation Measures

| No. | Valued Component/Intermediate Component and Effect | Proposed Mitigation Measure | Timing | Legal Requirement? | Responsible Agency |
|----------------------|---|---|------------------------------|--------------------|--------------------|
| Environmental | | | | | |
| M1 | River Hydraulics and River Morphology: <ul style="list-style-type: none"> Minor increase in volume of suspended sediment during Tunnel decommissioning activities | <ul style="list-style-type: none"> Measures to mitigate effects from turbidity or elevated levels of suspended sediments; also see mitigation M4. | Construction | N/A | |
| M2 | River Hydraulics and River Morphology: <ul style="list-style-type: none"> Temporary lowering of riverbed between the Tunnel and the Lulu Island-Delta water main | <ul style="list-style-type: none"> Early engagement and coordination with Metro Vancouver (owner of the water main). Monitoring riverbed within 100 m upstream and downstream of the water main. Regular monitoring at appropriate intervals will begin during Tunnel removal. Stockpiling appropriate-sized rock near the Project site for priority scour protection repairs at the water main crossing, if required. Establishing on-call contracts with a qualified registered professional and a qualified marine contractor prior to Tunnel removal to facilitate the design and implementation of scour protection repairs on short notice if required. | Project Planning/ Ongoing | N/A | |
| M3 | Sediment and Water Quality: <ul style="list-style-type: none"> Sediment generation, or re-suspension associated with Tunnel removal Localized disturbance of surficial sediments during installation of temporary barging facilities, and removal of Tunnel segments | <ul style="list-style-type: none"> Removing fill materials adjacent to the Tunnel will be conducted using appropriate equipment to minimize re-suspension of sediments. Transporting removed fill material off-site using appropriate sediment containment systems. | Construction | N/A | |

|-----|--|--|--------------|--|---|
| M6 | <p>Underwater Noise:</p> <ul style="list-style-type: none"> Temporary exceedance of the auditory injury threshold for marine mammals during construction activities within and near the marine environment | <ul style="list-style-type: none"> Scheduling activities with the potential to generate underwater noise levels above the auditory threshold for injury to marine mammals during periods of low tide, when work can be completed under shallow water conditions or in the dry. Conducting underwater noise monitoring during applicable activities to ensure underwater noise levels do not exceed auditory injury thresholds. Developing a Marine Mammal Management Plan as part of the CEMP (see M15). | Construction | N/A | |
| M7 | <p>Fish and Fish Habitat:</p> <ul style="list-style-type: none"> Temporary, localized streamside disturbance, erosion, or sedimentation resulting in increased total suspended solids levels | <ul style="list-style-type: none"> Developing and implementing environmental protection measures that will be outlined in the Fish and Fish Habitat Management Plan, and Erosion and Sediment Control Plan, components of the CEMP, as well as an Operational Environmental Management Plan (OEMP). The plans will describe the mitigation measures to avoid or minimize potential erosion, sedimentation, or increased total suspended solids. Conducting instream works in accordance with provincial standards and best practices, including the Ministry's <i>Environmental Best Practices for Highway Maintenance Activities</i> and the B.C. <i>Water Sustainability Act</i> (where applicable). | Construction | <i>Water Sustainability Act</i> permitting | Ministry of Forests, Lands, and Natural Resource Operations |
| M8 | <p>Fish and Fish Habitat:</p> <ul style="list-style-type: none"> Loss of fish habitat | <ul style="list-style-type: none"> Minimizing potential encroachment on fish habitat, as well as potential effects resulting from instream works, ground disturbance and clearing and grubbing of riparian vegetation, by limiting Highway 99 improvements to the Highway 99 ROW. Developing and implementing a Fish Habitat Offsetting Plan. Offsetting unavoidable footprint effects through the development of comparable habitat. | Construction | N/A | |
| M9 | <p>Fish and Fish Habitat:</p> <ul style="list-style-type: none"> Temporary changes in ambient water quality during Tunnel removal | <ul style="list-style-type: none"> Implementing mitigation measures to maintain turbidity levels within the B.C. WQG and CCME <i>Water Quality Guidelines for the Protection of Aquatic Life</i>, including: <ul style="list-style-type: none"> undertaking instream activities within the applicable least-risk timing window to the extent that is technically feasible and viable using appropriate equipment to minimize the amount of re-suspended sediment. | Construction | N/A | |
| M10 | <p>Fish and Fish Habitat:</p> <ul style="list-style-type: none"> Temporary changes in ambient water quality | <ul style="list-style-type: none"> Conducting works in and around upland ditches within the applicable timing windows, in isolation of water flows, and with fish salvages as required. Undertaking works in and around upland ditches in accordance with provincial standards and best practices, including the Ministry's <i>Standard Specifications for Highway Construction</i> (B.C. MOTI 2012), and complying with the B.C. <i>Water Sustainability Act</i>. <p>Operations:</p> <ul style="list-style-type: none"> Designing roadside ditches to maintain ambient water quality and pre-development flow regimes. Incorporating vegetated shoulders and drainage swales, stormwater storage facilities to control runoff rates, headwall structures in culverts, wide bottom ditches, and stormwater management ponds. | Construction | <i>Water Sustainability Act</i> permitting | Ministry of Forests, Lands, and Natural Resource Operations |
| M11 | <p>Fish and Fish Habitat:</p> <ul style="list-style-type: none"> Direct or indirect fish injury or mortality to fish | <ul style="list-style-type: none"> Describing requirements for application of appropriate fisheries timing windows in the Fish and Fish Habitat Management Plan (see M7). | Construction | N/A | |

| No. | Valued Component/Intermediate Component and Effect | Proposed Mitigation Measure | Timing | Legal Requirement? | Responsible Agency |
|-----|--|--|--------------|--------------------|--------------------|
| M12 | Fish and Fish Habitat: <ul style="list-style-type: none"> Physical injury, mortality, or behavioural disturbance to fish through exposure to underwater noise during construction | <ul style="list-style-type: none"> Adhering to BMPs and other standard industry practices that set appropriate sound thresholds for fish protection during activities that may generate underwater noise. Implementing measures to mitigate underwater noise effects, including undertaking underwater noise monitoring (see M6 and M15). | Construction | N/A | |
| M13 | At-risk Amphibians: <ul style="list-style-type: none"> Temporary loss of or change in at-risk amphibian habitat during instream works including clearing and grubbing of riparian vegetation, temporary de-watering of upland ditches, and installation of temporary drainage structures | <ul style="list-style-type: none"> Developing and implementing mitigation to prevent or minimize potential effects on at-risk amphibians as part of the CEMP. Developing and implementing the Erosion and Sediment Control Plan, Fish and Fish Habitat Management Plan, and Terrestrial Vegetation and Wildlife Management Plan to further prevent or minimize potential adverse effects on at-risk amphibians (see M4, M7, and M16). Minimizing Project footprint disturbance by flagging construction boundaries in the field and marking clearing perimeters to minimize the potential for accidental encroachment on forested areas and wetlands that may be suitable living habitat for at-risk amphibians. Offsetting Project footprint effects on the cattail marsh near Green Slough through the creation of a cattail marsh within a biofiltration pond near the existing south portal of the Tunnel. Removing invasive species and garbage from the marsh and revegetating using native species in the area surrounding the new bridge support piers. Conducting monitoring during and after construction to ensure that it is functioning as intended. | Construction | N/A | |
| M14 | At-risk Amphibians: <ul style="list-style-type: none"> Mortality from vegetation grubbing and clearing, and instream construction activities | <ul style="list-style-type: none"> Conducting amphibian salvage and translocation as required to avoid or minimize potential Project-related mortality to at-risk amphibians (and other native amphibians) from instream works during Project construction. | Construction | N/A | |
| M15 | Marine Mammals: <ul style="list-style-type: none"> Physical injury or behavioural disturbance due to underwater noise | <ul style="list-style-type: none"> Developing and implementing a Marine Mammal Management Plan as part of the CEMP, which will describe measures to mitigate potential Project-related effects to marine mammals during construction activities and measures to minimize underwater noise. Applying measures to mitigate construction activities that may generate underwater noise (see M6). Conducting underwater noise monitoring during Project construction in the Fraser River South Arm and Green Slough to measure underwater noise levels and ensure that injury thresholds are not exceeded | Construction | N/A | |
| M16 | Vegetation: <ul style="list-style-type: none"> Overlap between at-risk plant communities and Project components | <ul style="list-style-type: none"> Developing and implementing a Terrestrial Vegetation and Wildlife Management Plan as part of the CEMP to minimize potential construction-related effects on vegetation. The plan will describe measures to minimize disturbance and loss of vegetation, prevent soil compaction, minimize clearing, and identify appropriate storage areas and reclamation requirements. Confining unavoidable overlap of cattail marsh adjacent to Green Slough to the edges of the marsh, where it will not affect the functionality of the ecosystem. Offsetting unavoidable Project footprint effects on cattail marsh near River Road by creating comparable cattail marsh habitat within Project alignment. Implementing environmental protection measures outlined in the CEMP during Project construction and operation to prevent or minimize potential effects on vegetation. The CEMP will include a Terrestrial Vegetation and Wildlife Management Plan, and an Invasive Species Management Plan. | Construction | N/A | |

| No. | Valued Component/Intermediate Component and Effect | Proposed Mitigation Measure | Timing | Legal Requirement? | Responsible Agency |
|-----|--|--|--------------|---------------------|---|
| M18 | Vegetation: <ul style="list-style-type: none"> Invasive species | <ul style="list-style-type: none"> Developing and implementing an Invasive Species Management Plan that includes site-appropriate monitoring and control methods for different species and conditions as part of the CEMP. Controlling invasive plant species during construction in accordance with the B.C. <i>Weed Control Act</i>, as well as species that are listed by the Invasive Species Council of Metro Vancouver. | Construction | N/A | |
| M19 | Terrestrial Wildlife: <ul style="list-style-type: none"> Loss of terrestrial wildlife and wildlife habitat as a result of clearing and grubbing for Project components | <ul style="list-style-type: none"> Implementing measures described in Terrestrial Vegetation and Wildlife Management Plan (see M16). Flagging sites important to wildlife species in the field and marking them on Project plans to provide a visual barrier to contractors, indicating that such areas need special provisions (as specified in Environmental Protection Plans for the site) during construction. To the extent feasible, planning Project construction activities to coincide with least-risk timing windows for wildlife. The Terrestrial Vegetation and Wildlife Management Plan will define timing windows during which there is potential for adverse effects on terrestrial and semi-aquatic wildlife; identifying low-risk periods for construction and operation activities. Conducting nest surveys in advance if clearing and grubbing must proceed during the bird breeding season to confirm the presence/absence of breeding birds, and location of nesting sites. Construction can proceed if identified nests are unoccupied and are not of a species protected year-round by the <i>Wildlife Act</i>. Undertaking wildlife salvage prior to clearing and grubbing if there are locations of known small mammal occurrences. | Construction | <i>Wildlife Act</i> | Ministry of Forests, Lands, and Natural Resource Operations |
| M20 | Terrestrial Wildlife: <ul style="list-style-type: none"> Temporary sensory disturbance to terrestrial wildlife during construction | <ul style="list-style-type: none"> Applying mitigation to address construction-related effects on noise (see M25). Applying mitigation to address construction-related effects on air quality (see M24). Implementing measures within Terrestrial Vegetation and Wildlife Management Plan (see M16). | Construction | N/A | |
| M21 | Terrestrial Wildlife: <ul style="list-style-type: none"> Sensory disturbance to terrestrial wildlife during Project operation | <ul style="list-style-type: none"> Incorporating standard practices for lighting systems for highways and roadways under the jurisdiction of the Ministry into the Project design. The lighting design will address safety requirements and will minimize sensory disturbance to terrestrial wildlife from changes in the ambient light environment and the currently lit areas of Highway 99. | Operation | N/A | |
| M22 | Terrestrial Wildlife: <ul style="list-style-type: none"> Increased mortality of barn owls as a result of collision with vehicles. | <ul style="list-style-type: none"> Constructing highway width in accordance with applicable geometric standards, and minimally vegetating the right-of-way, which can limit infrequently disturbed grass habitat that is suitable for barn owl prey resources (i.e., small mammals including Townsend's vole), thus reducing barn owl attractiveness to the Project alignment and lowering the collision risk. Installing flight deflectors such as hedgerows at appropriate locations along the highway. | Operation | N/A | |
| M23 | Terrestrial Wildlife: <ul style="list-style-type: none"> Removal of the Deas Slough Bridge, resulting in the loss of barn swallow nesting habitat | <ul style="list-style-type: none"> Approach of the new bridge in the immediate vicinity of the Deas Slough Bridge is expected to provide nesting opportunities for barn swallows. | Construction | N/A | |

| No. | Valued Component/Intermediate Component and Effect | Proposed Mitigation Measure | Timing | Legal Requirement? | Responsible Agency |
|---------------|---|---|-------------------------|---|--------------------|
| M24 | Air Quality: <ul style="list-style-type: none"> Emissions and road dust generated from vehicles and equipment, resulting in a temporary change in air quality during construction | <ul style="list-style-type: none"> Developing and implementing an Air Quality and Dust Control Management Plan as part of the CEMP, which will describe measures to control and minimize fugitive dust and other airborne emissions associated with construction equipment, demolition, and other decommissioning activities, as well as soil handling. Including industry standards and best management practices in the Air Quality and Dust Control Managing road dust during Project operation by cleaning the road where dirt, debris, sand, and gravel have accumulated. | Construction | N/A | |
| M25 | Atmospheric Noise: <ul style="list-style-type: none"> Traffic-related changes in noise levels at adjacent receptors during construction | <ul style="list-style-type: none"> Developing and implementing a Noise Management Plan as part of the CEMP, which will describe standard best practices and Project-specific mitigation measures to prevent or minimize community impacts due to temporary construction-related noise. | Construction | N/A | |
| M26 | Atmospheric Noise: <ul style="list-style-type: none"> Traffic-related changes in noise levels at adjacent receptors during operation | <ul style="list-style-type: none"> Undertaking mitigation in accordance with the Ministry's 2014 Noise Policy. Conducting post-project, 24-hour noise monitoring at selected, representative noise receiver locations to confirm noise predictions and assess the effectiveness of mitigation measures. | Operation | N/A | |
| Social | | | | | |
| M27 | Traffic: <ul style="list-style-type: none"> Temporary delays and lane closures during construction | <ul style="list-style-type: none"> Developing and implementing a Traffic Management Plan that will identify and describe approaches for managing traffic and communicating with stakeholders and the public during the construction period. This will include: <ul style="list-style-type: none"> Traffic management strategies, including access routes, to ensure continued movement of traffic on the Highway 99 corridor and initiatives to minimize disruption and maximize predictability for Highway 99 travellers, cycling and pedestrian network users, and nearby residents and businesses Safety requirements to maintain a safe corridor at all times for travellers and workers Communication and engagement activities Incident management and response plans | Construction | N/A | |
| M28 | Marine Use: <ul style="list-style-type: none"> Temporary change to commercial navigation, commercial, recreational, and Aboriginal fisheries navigation, and recreational navigation | <ul style="list-style-type: none"> Submitting a Notice of Works form to Transport Canada to address the requirements of the <i>Navigation Protection Act</i> for construction activities that may interfere with navigation. Developing and implementing measures to maintain the navigation channel during construction, including establishing navigation protection zones. Developing a Marine Access Management Plan that includes measures to minimize potential construction-related access effects on marine users. This will include communications protocols to establish and advise of instream construction activities, including periods of vessel restrictions. | Construction | <i>Navigation Protection Act</i> permitting | Transport Canada |
| M29 | Land Use: <ul style="list-style-type: none"> Potential acquisition of additional portions of adjacent land parcels to accommodate Project alignment, which may influence land use within or adjacent to those parcels | <ul style="list-style-type: none"> Designing the Project to be largely within the Highway 99 right of way, avoiding effects to nearby land uses where possible. Incorporating land use considerations in the Traffic Management Plan (see M27), Marine Access Management Plan (see M28), Noise Management Plan (see M25), and Air Quality and Dust Control Management Plan (see M24). | Construction, Operation | N/A | |

| No. | Valued Component/Intermediate Component and Effect | Proposed Mitigation Measure | Timing | Legal Requirement? | Responsible Agency |
|-----|---|--|--------------|--------------------|--------------------|
| M30 | Land Use: <ul style="list-style-type: none"> Temporary restricted use of Millennium Trail, Island Tip Trail, and recreational watercraft in Deas Slough during construction | <ul style="list-style-type: none"> Reconnecting, restoring, or enhancing trails following Project construction, in consultation with Metro Vancouver Parks and Delta Department of Parks, Recreation and Culture. | Construction | N/A | |
| M31 | Land Use: <ul style="list-style-type: none"> The new bridge will add noticeable visual features to the landscape and result in changes in visual conditions at certain viewpoints | <ul style="list-style-type: none"> Addressing potential effects to visual quality where feasible (see M40). | Operation | N/A | |
| M32 | Agricultural Use: <ul style="list-style-type: none"> Temporary changes to irrigation and drainage systems | <ul style="list-style-type: none"> Constructing the Project in a way that enables key ditch systems to continue to function and water quality to be suitable for irrigation. Developing an Agricultural Management Plan as part of the CEMP, which will describe standard best practices and Project-specific mitigation measures to prevent or minimize potential effects on drainage, water quality and irrigation, farm infrastructure and operations, and soil conservation, storage, and reclamation. The plan will include measures to reconstruct or upgrade ditches in accordance with the B.C. <i>Agricultural Drainage Criteria</i>. | Construction | N/A | |
| M33 | Agricultural Use: <ul style="list-style-type: none"> Temporary changes to transportation and access | <ul style="list-style-type: none"> Implementing a Traffic Management Plan during construction (see M27) that will facilitate the efficient movement of agricultural traffic and mitigate temporary disruptions and increased traffic during construction. The plan will be shared with the agricultural community prior to implementation. | Construction | N/A | |
| M34 | Agricultural Use: <ul style="list-style-type: none"> Temporary disturbance to livestock | <ul style="list-style-type: none"> Mitigating sensory disturbances related to air quality (see M24) and noise (see M25). | Construction | N/A | |
| M35 | Agricultural Use: <ul style="list-style-type: none"> Temporary potential for accidental spills of deleterious substances | <ul style="list-style-type: none"> Incorporating measures to be undertaken in the event of a spill or release of deleterious substance in the CEMP. | Construction | N/A | |
| M36 | Agricultural Use: <ul style="list-style-type: none"> Temporary degradation of ditches due to sedimentation | <ul style="list-style-type: none"> Developing and implementing a Erosion and Sediment Control Plan (part of the CEMP) to prevent soil erosion and sediment transport. | Construction | N/A | |
| M37 | Agricultural Use: <ul style="list-style-type: none"> Temporary degradation of agricultural soils | <ul style="list-style-type: none"> Reducing the potential for degradation of agricultural soils during Project construction. Salvaging topsoil and subsoil along temporary roads or laydown areas, and making it available for agricultural use if appropriate. Developing and implementing an Agricultural Management Plan (see M32). Including measures to be implemented to prevent and manage spills in the CEMP (see M35). Developing and implementing an Erosion and Sediment Control Plan (see M36). | Construction | N/A | |

| No. | Valued Component/Intermediate Component and Effect | Proposed Mitigation Measure | Timing | Legal Requirement? | Responsible Agency |
|-----------------|--|---|------------------|--|------------------------------|
| M38 | Agricultural Use: <ul style="list-style-type: none"> Temporary changes to farm utilities and infrastructure | <ul style="list-style-type: none"> Informing potentially affected farm operators in advance of any potential disruption to utility services—specifically power and natural gas supply—during construction. Minimizing the Project footprint and consolidating farm parcels into more economically viable units; this measure will also mitigate the effects of the Project on stakeholder perceptions of agricultural land in the LAA. | Construction | N/A | |
| M39 | Agricultural Use: <ul style="list-style-type: none"> Changes to three parcels of agricultural land within the Project alignment | <ul style="list-style-type: none"> Making suitable land parcels available for agricultural use to offset the acquisition of small portions of farmland for the Project. These parcels are located adjacent to existing farm fields, and can be restored to comparable land capability, enhancing their agricultural potential. Project-related offsetting is expected to result in a net gain of agricultural land. | Project Planning | <i>Agricultural Land Commission Act</i> permitting | Agricultural Land Commission |
| M40 | Visual Quality: <ul style="list-style-type: none"> Introduction of an anthropogenic feature into the existing landscape | <ul style="list-style-type: none"> Installing vegetation buffers to partially reduce the visual effects of the Project in select areas on either side of the new bridge. | Project Planning | N/A | |
| Heritage | | | | | |
| M41 | Heritage Resources: <ul style="list-style-type: none"> Chance encounter of an unidentified archaeological or heritage resource during construction | <ul style="list-style-type: none"> Developing and implementing an Archaeological and Heritage Resources Management Plan as part of the CEMP, which will include chance find procedures to be implemented if previously unknown heritage resources are encountered during Project construction. Developing the plan with guidance, where applicable, from the B.C. Archaeology Branch, in accordance with existing Ministry policies and procedures, and in consultation with Aboriginal groups. Undertaking further assessment of previously inaccessible sites, if required, under the terms and conditions of a <i>Heritage Conservation Act</i> permit prior to or during Project construction. | Construction | N/A | |
| Health | | | | | |
| M42 | Human Health: <ul style="list-style-type: none"> Change in atmospheric noise during construction and operation | <ul style="list-style-type: none"> Developing and implementing a Noise Management Plan (see M25), which will include communicating with potentially affected parties. Implementing noise mitigation in accordance with the Ministry's 2014 Noise Policy (see M25 and M26). | Operation | N/A | |
| M43 | Human Health: <ul style="list-style-type: none"> Change in air quality during construction | <ul style="list-style-type: none"> Developing and implementing an Air Quality and Dust Control Management Plan (see M24). | | N/A | |

Glossary

| Term | Definition |
|---|---|
| acoustic Doppler current profiler (ADCP) | Technology that measures water current velocities using the Doppler effect of sound waves scattered back from particles within the water column. |
| anabranching | Describes a river with multiple channels separated by stable islands that are large relative to the size of the channels and which divide the flow at discharges up to and including bankfull. |
| bed load | Sediment particles moving in direct contact with the bed by rolling, sliding and saltating. On the lower Fraser River, bed load consists almost entirely of sand-sized sediments. |
| bedforms | Feature that develops on a river bed due to the action of fluid flow over a moveable bed. |
| bed-material load | The transport rate of sediments derived from entrainment and erosion of the bed material deposits in the channel; can be transported both as bed load and as suspended bed material, and has a major influence on the stability of the channel. Also, that part of the total sediment load of a river that is composed of particle sizes present in appreciable quantities in the shifting portions of the bed. |
| computer aided design (CAD) | Software used to assist in the creation, modification, analysis, or optimization of a design. |
| channel conveyance | A measure of the hydraulic carrying capacity of a channel, related only to the cross-sectional dimensions of the channel. |
| draft | Depth of water that is required to safely float a ship. |
| dunes | A bedform that occurs in sand bed rivers and consists of migrating undulations in the river bed surface. |
| element | In a finite element model, the unit of subdivision of the model mesh. |
| entrainment, or sediment entrainment | Process by which sediment is incorporated into river flow as part of the action of erosion. |
| exceedance probability, annual exceedance probability | The probability of an event being greater than or equal to a given value; annual exceedance probability is the probability of an event being greater than a given value once or more than once in a given year. |
| flow split | The distribution of flow among individual channels in a multi-channel stream. |

| Term | Definition |
|---|--|
| flume | An artificial channel or trough for conducting water, often used in hydraulic research. |
| headcutting | The process of riverbed erosion that is characterized by the upstream progression of a knickpoint. |
| hindcast | A way of testing a numerical model by simulating a past event and comparing results with known outcomes. |
| hydrodynamics | The branch of fluid dynamics that deals with liquids, including hydrostatics and hydrokinetics. |
| king tide | An especially high tide |
| knickpoint | The location along a river where there is a locally steepened slope between lower gradient sections, and an upstream-migrating wave of erosion can occur or has occurred. |
| left bank, right bank | As seen by an observer looking downstream. For the Fraser River, the left bank corresponds to the south bank; the right bank corresponds to the north bank. |
| LiDAR | Light detection and ranging remote sensing technology |
| mesh | In a finite element model, the model representation of the prototype domain, composed of elements. |
| morphodynamics | The study of riverbed changes due to erosion and sedimentation. |
| multibeam surveys | Bathymetric surveys conducted using a transducer that emits an acoustic pulse in a multi-directional cone of energy directed downward towards the bed to measure water depth below the ship. The high density of data collected provides a high resolution of features on the bed. |
| node | In a finite element model, a point common to two or more elements. |
| non-exceedance probability, annual non-exceedance probability | The probability that no event greater than a given value will occur; annual non-exceedance probability is the probability that an event having a given magnitude will not be exceeded in a given year. |
| planform | Channel shape as viewed from above |
| reach | Any specified length of a stream |
| river training | River engineering works intended to reduce hydraulic hazards by re-aligning and controlling flow patterns within the channel, (e.g., spurs, groynes, guide banks, etc.). |

| Term | Definition |
|---------------------|---|
| single-beam surveys | Bathymetric surveys conducted using a transducer that emits an acoustic pulse in a single, narrow cone of energy downward towards the bed to measure water depth directly beneath the ship. |
| suspended load | Sediment particles maintained in the water column by the turbulence of the flow, including fine material constantly maintained in suspension and sand temporarily entrained from the river bed (the suspended bed material load). |
| sill | A non-erodible or erosion resistant horizontal layer or structure protruding above the surrounding riverbed, usually forming a hydraulic control. |
| thalweg | The path along a river channel of maximum depth and usually velocity. |
| velocity | A vector quantity consisting of speed and direction; the speed of something in a given direction |
| velocity magnitude | The speed component of the velocity vector |
| washload | Fine sediment load that can be maintained in suspension by the turbulence of the flow and consequently is not found in appreciable quantities in the river channel bed material; in the lower Fraser River, wash load sediments consist of clay, silt and fine sand (less than 0.177 mm). |

1.0 Introduction

This technical volume presents the objectives, methods, and findings of the Fraser River hydraulics and morphology study undertaken to support the environmental assessment of the George Massey Tunnel Replacement Project (Project).

1.1 Project Background

The British Columbia Ministry of Transportation and Infrastructure (Ministry) is proposing the Project to address current safety and congestion challenges, meet forecast population and employment growth, and ensure Highway 99 continues to meet regional, provincial and national transportation needs. The Project involves replacing the George Massey Tunnel crossing (Tunnel) of the Fraser River South Arm with a new bridge within the existing Highway 99 right-of-way (ROW), replacing the Westminster Highway, Steveston Highway, and Highway 17A interchanges, widening Highway 99 between Bridgeport Road in Richmond and Highway 91 in Delta, and decommissioning the Tunnel. The Project's location is shown on **Figure 2-1**.

1.2 Study Overview and Objectives

The purpose of the study is to assess the potential changes in Fraser River hydraulics and morphology due to removal of the Tunnel. River hydraulics is the study of flow in rivers, and is most often related to flow patterns, water levels, and velocities. The study of river morphology (i.e., fluvial geomorphology) focuses on river forms and processes, and is primarily concerned with the interaction between fluid flow and the erodible materials in the channel bed and banks (Knighton 1998). This study reviews potential changes to water levels, velocities and flow patterns resulting from Tunnel removal, and their influence on sedimentation and erosion within the Fraser River. **Figure 2-1** shows locations of key interest in the study.

Potential changes due to the new bridge crossing are not discussed. The new bridge is proposed as a clear-span crossing, eliminating the potential for instream changes resulting from the structure. It has been assumed that the clear-span bridge will require no river-training structures (i.e., guide banks, spurs, etc.) or instream collision-protection structures, and that any upgrades to bank protection near the proposed bridge pylons will retain the shape and footprint of the existing bank protection works.

2.0 Methods

2.1 Assessment Area

The regional assessment area (RAA) includes the Fraser River South Arm from just upstream of Annacis Island to the Fraser River estuary, including Sturgeon Bank and Roberts Bank (**Figure 2-2**).

The local assessment area (LAA), where Project-related changes are likely to occur, extends from Fraser River South Arm from just upstream of Tilbury Island to the mouth of the River (**Figure 2-3**). Approximately 35 km upstream of the mouth, the Fraser River splits around Lulu Island and Annacis Island at the New Westminster Trifurcation. North of Lulu Island, flow enters the Fraser River North Arm. The Fraser River South Arm splits around Annacis Island to form Annieville Channel and Annacis Channel. Downstream of Tilbury Island, flow along the Fraser River South Arm is further dissected around islands in the area bounded by the main channel, Ladner Reach, and Sea Reach, and then around Westham Island, with a portion of the flow travelling down Canoe Passage. The water level in this lower reach is dominated by the tides (winter tides in particular), as opposed to Fraser River discharge.

2.2 Temporal Scope

The three temporal cases in this assessment are identified as follows:

- Existing conditions
- Future conditions with the Project
- Future conditions without the Project

The characterisation of existing conditions was based on data from recent years. Model geometry was comprised of Fraser River bathymetry data from PWGSC, CRA Canada Surveys Inc. (CRA), and Northwest Hydraulic Consultants Ltd. (NHC) surveys completed in 2014. Wind, tide, and Fraser River flow data from 2012 were used as inputs to the numerical model. The year 2012 was typical in terms of storm frequency and intensity, but was above average for discharge from the Fraser River in the late spring and early summer. For the fall and winter periods, 2012 discharge corresponds with the mean.

Assessment of future conditions with the Project was based on the construction and operation phases of the Project as described in **Section 3.1** of the Application. Tunnel removal is anticipated to begin in August/September, and be undertaken within the least-risk timing window. Infilling of the trench feature expected to be left on the river bed by the removal of the Tunnel was simulated in the model based on data from August 16, 2012 to March 14, 2013. Longer-term changes in the river were assessed based on the post-infilling riverbed geometry. Post-infilling analysis in the model was carried out based on data from the freshet period of May 26 to July 27, 2012. The freshet period was selected for modelling because this is when the majority of sediment transport occurs in the Fraser River. The 2012 freshet in the Fraser River had a return period on the order of 20 years (B.C. FLNR 2014), and the high freshet flow scenario provided the condition for evaluating the upper end of potential changes to river hydraulics and sedimentation. Availability of data for the year 2012 facilitated model calibration.

The Fraser River is a dynamic environment with seasonal patterns and climatic influences. Climate change will have an impact on this natural variability in the long term. Changes to water levels as a result of sea level rise and to flows as a result of changes in precipitation are anticipated. For comparison purposes, a discussion of the influence of climate change on Fraser River hydraulics and morphology without the Project in place is provided.

2.3 Study Methods

Two methods were used to assess potential changes to river hydraulics and morphology due to the Project:

1. Interpretive geomorphic studies using historical data, site observations, and measurements
2. Numerical modelling of hydrodynamics and morphodynamics

2.3.1 Interpretive Geomorphology

An interpretive geomorphology approach was undertaken to supplement the numerical modelling results and enable a better understanding of the morphological evolution of the lower Fraser River and estuary. Tasks included the following:

- Literature review – Previous field, model, and theoretical studies were reviewed to understand the environment and driving forces at work near the Tunnel and interpret the results of the numerical modelling in this light.
- Aerial photograph interpretation – Aerial photographs of the local assessment area (LAA) spanning the years 1938 to 2009 were analyzed. They provide insight into the planform changes that have taken place on the lower Fraser River since 1938 and the role of natural or anthropogenic factors in driving these changes.
- Bathymetric surveys – Water main crossings on the Fraser River have been surveyed regularly by the Greater Vancouver Water District since 1962. Data were also obtained from bathymetric surveys of the lower Fraser River conducted in 1988/89, 2000/01, 2008/09 and 2014 by Public Works and Government Services of Canada (PWGSC).

2.3.2 Numerical Modelling

Potential Project-related changes to river hydraulics and morphology in the Fraser River were investigated using the TELEMAC-MASCARET modelling system. The hydrodynamic program TELEMAC-3D was applied to compute various physical processes of river hydraulics, and the SISYPHE program was used to compute sediment transport. The TELEMAC-3D program first computes hydraulic conditions in the lower Fraser River. Bed changes (scour and deposition) around the Tunnel were computed by coupling the sediment transport and morphodynamic model SISYPHE to TELEMAC-3D. SISYPHE uses the hydraulic information from TELEMAC-3D to compute scour and deposition of the riverbed. The new bed elevation computed by SISYPHE is fed back into TELEMAC-3D to re-compute the flow hydrodynamics (**Figure 2-4**).

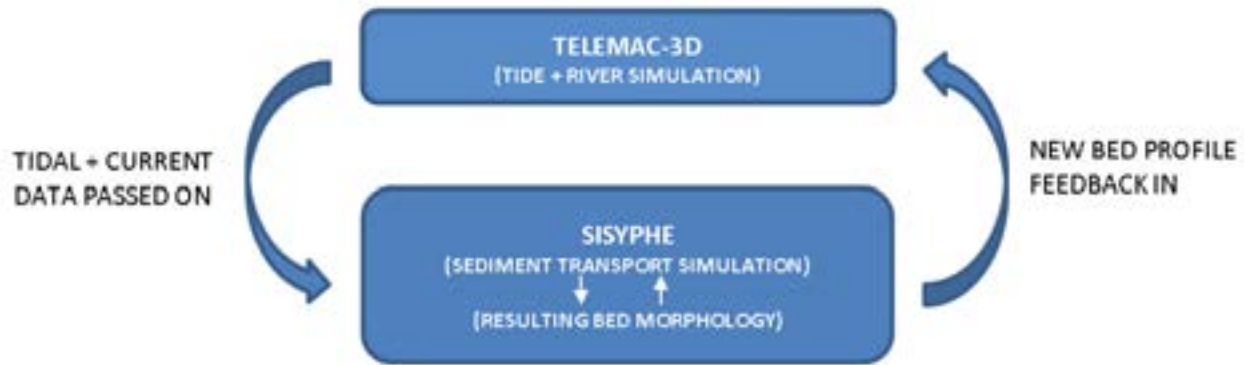

Figure 2-4 TELEMAC model coupling flow diagram

The resulting model serves as a tool for understanding the potential changes to river hydraulics and morphology due to Tunnel removal; however, it cannot be used to predict the long-term behaviour of the river. Future changes in physical inputs such as sea level rise, changes to hydrograph timing and shape, sediment supply, and alterations to the river channel (i.e., channel deepening, land reclamation) will influence future hydraulics and morphology in ways that cannot be predicted by the model. Rather, the model captures the most important physical processes in lower Fraser River and assists in predicting the consequences of a specific change to the system. As with all numerical models, it is subject to uncertainty due to reasonable limits on the collection and incorporation of input data, approximation of hydraulic and sediment transport processes, and natural variability. Model results must be understood in the context of known river behaviour and interpreted using professional judgement.

2.4 Tunnel Description

As discussed in **Section 1.2**, the river hydraulics and morphology study focussed on the potential changes due to Tunnel removal. Three options have been studied: existing conditions, full Tunnel removal, and partial Tunnel removal. These options are discussed further in **Section 3.1**.

3.0 Existing Tunnel Conditions

The Tunnel is located on the Fraser River South Arm between km 18 and 19 (**Figure 2-1**). As part of Tunnel construction, which was complete by 1959, concrete sections were floated into position and allowed to sink into a trench dredged out of the sandy river bottom. In the immediate vicinity of the Tunnel crossing lies Deas Dock, which was dredged and built in 1957, and is now used as a maintenance facility for BC Ferries. The Tunnel is 629 m long and consists of six concrete segments, each 105 m in length. The Tunnel is 23.8 m wide and 7.3 m high. Simplified schematics of the Tunnel are shown in **Figure 3-1** and **Figure 3-2**.

The Tunnel is protected from scour and erosion with riprap and flexible concrete mattresses. A rock apron composed of 680 kg (1,500 lb) rock covers the Tunnel. Beneath that is a layer of 227 kg (500 lb) rock. A 3.8 cm (1½”) flexible concrete mattress is keyed into the rock protection and extends upstream and downstream from the Tunnel with 227 kg (500 lb) rock overburden (**Figure 3-1**). The top of the scour protection layer was constructed to be flush with the riverbed in the central channel. As-built drawings of the Tunnel scour protection are included in **Attachment A**.

¹ Retrieved from MMM Group Ltd.

3.1 Proposed Tunnel Decommissioning Alternatives

The proposed Tunnel decommissioning is expected to occur once the new bridge is open to traffic. The assumed methodology involves removing the rock apron/ballast from the top of the structure, excavating beneath the Tunnel segments to break suction, and then floating the pre-cast concrete Tunnel segments to the surface. Tunnel decommissioning is assumed to take several months to complete. Two options for Tunnel removal are considered in this study: removal of six elements (full tunnel removal), and removal of four elements (partial tunnel removal).

3.1.1 Full Tunnel Removal

With the full Tunnel removal option, all six Tunnel segments, rock apron, and concrete mattress would be removed, leaving a trench of approximately 10 m in depth in the riverbed. The model assumes that both the north and south banks will be reconstructed to blend with adjacent banks and armoured with riprap where they have been disturbed by Tunnel removal.

3.1.2 Partial Tunnel Removal

With the partial Tunnel removal option, the two Tunnel segments located partially within the banks (TE1 and TE6 in **Figure 3-1**) would be left in place, and the four segments in the river channel would be removed, leaving an excavated trench. Since the end segments are mostly buried in the banks, channel conveyance at the crossing under this option is similar to that with the full Tunnel removal option. It has been assumed that rock would be placed around the nose of the two end segments at a 2H:1V slope to avoid adverse hydraulics and undermining of the Tunnel segments. The segments are expected to be filled with sand or gravel such that there would be no large voids within them.

4.0 Physical Setting

4.1 Fraser River Flows and Sediment Loads

4.1.1 Flows

The Fraser River drains a 232,000 km² area of southern B.C., making it the largest river on the west coast of Canada. Near the town of Mission, 85 km from the Strait of Georgia, the river changes abruptly from an anabranching gravel bed to a meandering sand-bed single channel. The reach from New Westminster to the Strait of Georgia represents the modern delta. At this location, 35 km from the river mouth, the main channel splits into the North Arm and South Arm. The North Arm further divides into the Middle Arm, and all three branches discharge into the Strait of Georgia.

The Fraser River has a snowmelt-dominated flow regime, with the discharge typically rising in April, peaking between May and July (the freshet period) and then receding during the autumn and winter months. **Figure 4-1** shows minimum, mean, maximum annual flow hydrographs for the Fraser River at Hope, 180 km upstream from the mouth. Flows in the lower Fraser River are often referenced to Hope since flows are free of tidal influence here, and the continuous gauge record extends back to 1912. The year 2012 is also shown because it was selected for the numerical modelling analyses (**Section 6.4**). Average peak flow of the Fraser River at Hope is about 7,000 m³/s in June; the average low flow is approximately 850 m³/s in March.

Figure 4-1 Annual Hydrographs of Fraser River at Hope (Retrieved from Government of Canada 2014).

4.1.2 Flow Patterns

The Fraser River South Arm divides just below Deas Island (18 km upstream from the Strait of Georgia) into Ladner Reach, and then again into Canoe Passage. Estimates of the flow splits in the various branches have changed over time due to the effects of river training and dredging; estimation is also complicated by the tidal influence on the flow. In May to June 2005, PWGSC conducted acoustic Doppler current profiler (ADCP) velocity-discharge measurements at several branches of the river in support of flood modelling investigations (NHC 2006). Those measurements indicated that the flow in the South Arm, upstream of Tilbury Island, was 90% of the flow at New Westminster; at the Kirkland Island bifurcation, the flow split is 81% in the Fraser River main channel (specifically, Woodward Reach) and 9% through Ladner Reach (**Attachment C: Tables 4, 5, and 6**).

Substantial effort has historically been devoted to maintaining a stable channel configuration through this reach of the river (Pretious and Thorne 1953), as discussed in **Section 5.1**. During the Tunnel planning stages, there was concern that the proposed Tunnel could alter flow patterns at the nose of Kirkland Island where Ladner Reach splits off, potentially resulting in scour and erosion in Ladner Reach (Pretious et al. 1957). Conversely, there are concerns about Tunnel removal altering flow patterns.

The Tunnel was expected to act like a weir, straightening flow near the riverbed. If this effect is indeed present, removing the Tunnel could allow flow to be directed more toward Ladner Reach. To address this issue, ADCP velocity measurements collected on March 27, 2014 near the bed and near the water surface along the centreline of the Tunnel (**Figure 4-2**) were examined. At the time, the river flow was approximately 6400 m³/s, and the water level was - 0.22 m Geodetic Datum (GD). The near-bed velocities were depth-averaged over the first metre above the bed, and the near-surface velocities were depth-averaged over the first metre below the water surface. The measurements show that the sill created by the top of the Tunnel does not appreciably change the direction of the flow near the bed. That is, the direction of flow near the bed is very close to the direction of flow near the water surface. This result suggests that the removal of the Tunnel will not change the velocity direction in its vicinity and is unlikely to change the flow splits in the surrounding area.

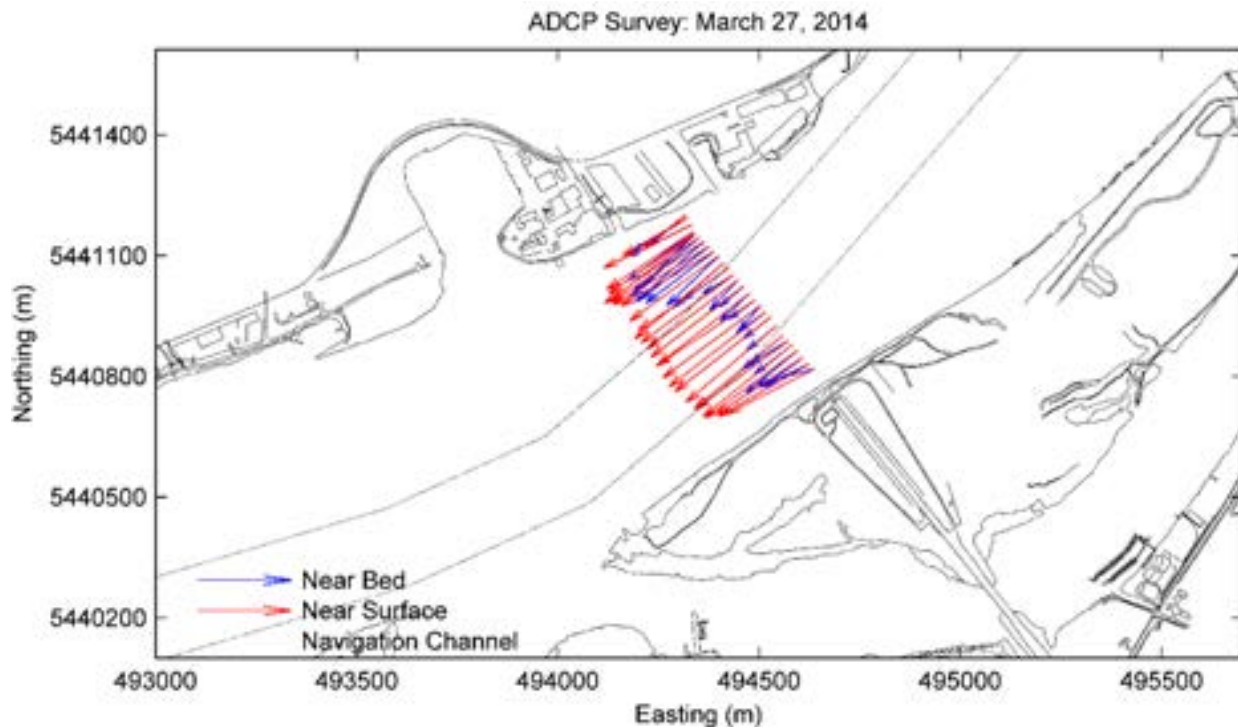

Figure 4-2 ADCP Velocity Measurements within 1 m Above the Bed (Blue) and within 1 m Below Water Surface (Red) for March 27, 2014 at 9:10 am.

4.1.3 Salt Wedge

Flow and sediment transport in the lower Fraser River are influenced by the presence of a salt water wedge, as is common in estuarine environments. The location of the salt wedge moves throughout each day in response to variations in tide height, as well as seasonally in response to variations in river discharge.

Stakeholder concerns have been raised regarding the potential changes to the extent of salt-wedge intrusion into the river as a result of Tunnel removal, specifically in the context of the influence of such changes on irrigation intake from the Fraser River South Arm. A separate study that involved hydrodynamic modelling was undertaken to investigate the behaviour of the salt wedge in the Fraser River and potential impact of Tunnel removal on its movement. A technical volume that provides further detail on the study is included as **Section 16.7**, and results of the study are discussed in **Section 5.4** (Agricultural Use) of the Application. A brief overview of the Fraser River salt wedge is provided below for context.

Ward (1976) found that during winter low flows, the wedge can extend up to 30 km upstream from Sand Heads (**Figure 2-1** and **Figure 4-3**). This observation contradicts the previously held hypothesis (Pretious 1972) that the sill formed by the Tunnel prevents the salt wedge from extending upstream of the Tunnel.

During freshet high flows, the maximum extent of salt water intrusion is less than 15 km. Therefore, the salt wedge is limited to downstream of the Tunnel during the freshet, and salt water is not present in the water column at the Tunnel during this period. Ward (1976) also found that stratification increases with increasing flow, and the wedge accordingly becomes better defined.

Patterns of sediment entrainment and deposition are affected by the salt wedge. As the salt wedge migrates upstream during flood tides, rapid deposition of suspended bed material occurs. This is presumably because of decreased turbulence in the upper non-saline layer and de-coupling of the river flow from the bed, preventing entrainment. During ebb tides, the salt wedge recedes and bed material re-suspension resumes due to increased turbulence as the tip of the salt wedge passes and is sustained by accelerating downstream flow (Kostaschuk, Luternauer, et al. 1989).

Kostaschuk et al. (1998) found that that sediment deposition during freshet occurs preferentially at the mouth of the river, where the tip of the salt wedge has been forced to retreat by high river flows. During periods of low flow, when the salt wedge has migrated upriver, bed-material transport from upstream is limited due to lower flows and weaker currents, and small amounts of bed material are deposited at the tip of the salt wedge.

Figure 4-3 Distance of Tip of Fraser River Salt Wedge as a Function of Discharge (Retrieved from Ward 1976)

4.1.4 Sediment Loads

Sediment loads on the lower Fraser River were measured by Water Survey of Canada (WSC) at Hope, Agassiz, Mission, and Port Mann during the period 1965 to 1986. Based on that data, the total suspended load averaged 16.5 million tonnes/year, and ranged from 12.3 million to 31.0 million tonnes/year (Tywoniuk 1972, McLean and Tassone 1988, McLean et al. 1999, NHC 2002a). In the lower Fraser River, fine sediments (also called washload) generally remain in suspension and therefore have little effect on sedimentation patterns. Of primary importance is the bed-material load, which is the bed load and the fraction of sediment load capable of depositing in the river, and therefore exerts an influence on river morphology. The bed-material load averaged 2.9 million tonnes/year, and ranged from 1.2 million to 8.9 million tonnes/year (NHC 2002a).

4.2 Dunes

Dunes are river bedforms that are characteristic of sand-bed channels. Multibeam surveys by CRA from 2014 show that dunes occur within a 1.2 km span centered over the Tunnel crossing. Large dunes have been observed from Port Mann (NHC 2009) to the mouth of the Fraser River. Dune height typically varies from 0.5 to 2.0 m in channels of approximately 12 m in depth, although individual dunes can be considerably larger (Church and McLean 1994).

Near Steveston, dune bedforms of up to four metres in height were measured in the channel. The morphology of dunes in the lower Fraser River varies with discharge (Kostaschuk, Church, et al. 1989); dunes are largest during freshet, then wash out and rebuild over the rest of the year. Results from multibeam surveys (Kostaschuk and MacDonald 1988) show that bedforms in the Sand Heads area have a curved, concave-downstream planform, and crests were continuous for at least 300 m across the river channel. The major bedforms are essentially two-dimensional, transverse dunes migrating directly downchannel. At the river mouth, migration rates were found to be at their maximum during the freshet period with an average migration rate of 14.8 m/day (Kostaschuk, Church, et al. 1989). Field observations by Pretious and Blench (1951) determined that migration occurred at rates of up to 50 to 75 m/day. The dunes produce periodic scour and fill as they migrate along the channel and can considerably increase total scour depths, damaging existing scour protection aprons and rock protection, and potentially exposing existing pipe crossings.

4.3 Water Levels

The Fraser River is tidally affected as far upstream as Mission. Tides in the Strait of Georgia are mixed semi-diurnal, generally having two highs and two lows of unequal height in each 24-hour day. The tidal range at Point Atkinson (**Figure 2-2**) located 23 km north of the mouth at Fraser River South Arm, is up to 5.2 m, and the mean tidal height is +3.1 m Chart Datum (CD). The fluctuations in water level at Fraser River at Deas Island (WSC gauge 08MH053) are shown in **Figure 4-4**, based on differences in hourly water levels for 2013. As at Point Atkinson, there is a seasonal variation, with the greatest amplitudes (the difference between high and low tide level) occurring during the months of April to July and October to January; values exceed 3.5 m during most of the months in these two periods. However, the tide signal is moderated by the influence of Fraser River flow at Deas Island. Nonetheless, extreme water levels in the lower estuary of the Fraser River are governed by the occurrence of high tides and storm surge in the winter season, rather than high discharges during the freshet.

Figure 4-4 Fluctuations in Daily Tidal Water Levels Calculated at Fraser River at Deas Island, WSC Gauge 08MH053².

Hourly water levels at the Fraser River at Deas Island gauge from 1969 - 1984³ were analyzed. Elevations in this gauge record are relative to Sand Heads datum (-2.603 m); therefore, data were corrected to GD prior to the analysis. Water levels ranged from -2.02 to +2.64 m. Corrected water levels were ranked, and annual probabilities of water level exceedence and non-exceedence were calculated (**Figure 4-5**). Exceedence and non-exceedence probabilities of a number of relevant water levels are listed in **Table 4-1**.

NHC assumed a preliminary design high water level of 2.0 m GD, which corresponds to the Canadian Hydrographic Service (CHS) high water datum at Deas Island. The HWL had an exceedence probability of 0.24% (i.e., in any hour there is a 0.24% chance that the water level will be higher than 2.0 m). The preliminary high water level was exceeded 298 times in the period of record (1969 – 1984).

² Data tabulated from Water Survey of Canada

³ The record was 88.2% complete within the period 1969 to 1984. Records are also available from May 2007 onward, but the gauge was relocated 200 m downstream from the original location, resulting in a shift in the record. The post-shift data were not included in the analysis.

Figure 4-5 Hourly Exceedence and Non-exceedence Probabilities for Fraser River Water Levels at Deas Island (WSC 08MH053, 1969 – 1984)

Canadian Hydrographic Service chart datum at Deas Island is -1.8 m, and had a non-exceedence probability of 0.02% (i.e., in any hour there is a 0.02% chance that the water level will be lower than -1.8 m). Water levels dropped below this level 19 times in the period of record.

It should be noted that the hourly probabilities referred to in this analysis do not account for seasonal variation. High water levels are clustered during the periods of largest tidal swings around the summer and winter solstices.

Table 4-1 Hourly Exceedence and Non-exceedence Probabilities for Fraser River Water Levels at Deas Island (WSC 08MH053, 1969 – 1984)

| Parameter | Description | Water Level (m GD) | Exceedence Probability (%) | Non-Exceedence Probability (%) |
|------------------|----------------------|--------------------|----------------------------|--------------------------------|
| Maximum | Highest recorded | 2.64 | 0.0008 | 99.9992 |
| | | 2.34 | 0.01 | 99.99 |

4.3.1 Water Level Changes

Water levels from three WSC hydrometric stations and two CHS tide gauges were analysed for long-term trends. Data from 1969 onwards were available from Mission (WSC 08MH024), Port Mann Pumping Station (WSC 08MH016), Deas Island (WSC 08MH053), New Westminster (#7654), and Point Atkinson (#7795). Minimum water levels were plotted for each year to highlight degradation and aggradation, since low water levels are sensitive to bed elevation changes.

The water level record upstream at Mission exhibits a subtle declining trend in minimum water levels between 1969 and the late 1980s, and levelling since then. The limited data available at Port Mann supports this observation with declining minimum water levels in the 2000s. The data record for New Westminster is the most complete, and follows a similar pattern as at Mission where minimum water level elevations clearly declined up to the late 1980s, after which the trend is flat (**Figure 4-6**). Similar to New Westminster, water levels at Deas Island decreased in the period from 1969 to 1984 and, even after the gauge was re-located, there has been a subtle downward trend.

The downward trend in minimum water levels is most likely a response to lowering of the riverbed, assuming that there have been no significant changes in discharge over this time period. Further discussion on riverbed lowering is provided in **Section 5.2**. Changes in low tide elevations could also affect the reported minimum water level; however, as shown in **Figure 4-6**, no corresponding downward trend in tide levels is apparent at Point Atkinson.

Figure 4-6 Minimum Water Levels Over Time at Gauges in the Assessment Area

4.4 River Infrastructure

4.4.1 Water Mains and Pipelines

Six water main crossings are present on the Fraser River downstream of New Westminster (**Figure 2-1**): Port Mann Main, Annacis Main No. 2 (Annieville Channel crossing), Annacis Main No. 3 (Annieville Channel crossing), Annacis Main No. 4 (Annacis Channel crossing), Tilbury Main, and Lulu Island–Delta Main.

The Lulu Island–Delta Main is nearest to the Project, situated approximately 600 m downstream of the Tunnel. Survey data indicate that scour occurs upstream of the water main, primarily in the left (south) part of the channel. **Section 8.2.2** discusses potential changes at the water main due to Tunnel removal.

There are nine other submerged pipeline crossings in the RAA (**Figure 2-1**) including three natural gas pipelines owned by Fortis (two at Tilbury Island and one downstream of the Port Mann Bridge); a gas pipeline located in Annacis Channel; an oil pipeline downstream of the Port Mann Fortis pipeline; and four submarine cables or cable areas downstream of the Tunnel.

There are scour protection aprons at several of these submerged pipeline crossings that create grade controls which affect river bed elevations upstream and downstream. The Lulu Island–Delta Main has a scour protection apron over its southern half that imparts a variable cross-channel elevation, but it is two metres lower than the Tunnel along the thalweg.

4.4.2 Bridge Crossings

Bridge crossings in the RAA include the Pattullo Bridge, built in 1936-37; the Alex Fraser Bridge, built in 1983-86 **Figure 2-1**; and the TransLink Advanced Light Rapid Transit bridge, situated just downstream of the Pattullo Bridge and constructed from 1987 to 1989. The Port Mann Bridge, 5 km upstream of the RAA boundary, was re-built in 2012.

4.4.3 River Training

With the growth of population and industry in the Lower Mainland, industrial use of the Fraser River estuary has increased, bringing with it an incentive for improving shipping access and protecting property and infrastructure on the river's banks. Extensive efforts to control the alignment of the river mouth started in 1910. The general locations of river training works described are shown in **Figure 4-7**.

The Steveston North Jetty was built in stages from 1911 to 1932, and the South Jetty was constructed between 1930 and 1932. The first Albion Jetty was constructed in 1935 (Morton 1949). The Woodward Island training wall and dam were constructed between 1922 and 1936 to further concentrate the main channel flow. Three pile dykes were constructed at Steveston (Shady) Island between 1925 and 1927 to train flow in the main channel; two on the southern bank and one upstream of the island. As a result of river training and bank protection, the channel in the estuary was significantly narrowed and deepened in comparison to conditions that existed in 1894 (McLean et al. 2007). The channelized section of river was also extended approximately nine kilometres seaward, mainly as a result of the Steveston North Jetty (**Figure 4-7**).

Two training structures, both completed in 1949, are in close proximity to the existing Tunnel: Deas Dam and the nose of Kirkland Island at the bifurcation. Deas Dam connects the upstream tip of Deas Island to the mainland, forcing flow down the main channel and closing off Deas Slough. The upstream tip of Kirkland Island was protected with a closed-pile bulkhead in 1949. Poor placement of the bulkhead had the unintended consequence of diverting excess flow into Ladner Reach (Pretious and Thorne 1953). The bulkhead was damaged in the 1952 freshet, and presumably not replaced or repaired. Currently, a rock training spur extends upstream from Kirkland Island's nose on the main channel side of the bifurcation, and what is believed to be the southern flank of the pile bulkhead remains in the Ladner Reach side.

4.4.4 Bank Hardening

Banks of the lower Fraser River have been hardened over the years by extensive riprap protection. Between 1927 and 1941, Woodward Island was riprapped on the main channel side. By 1953, the majority of the right bank had been protected with riprap from Steveston to upstream of the Tunnel (Pretious and Thorne 1953). The main channel bank of Deas Island has also been protected with riprap, although the time of construction is not known.

Figure 4-7 Known River Training Structures in the Fraser River Estuary, from the Mouth to Tilbury Island.

4.5 Dredging

The annual dredging effort along the Fraser River South Arm since 1960 has been extensive, with most of the sediment removals occurring downstream of New Westminster. Dredging volumes were greatest in the period between 1976 and 1990 and have declined in more recent years. Since 1999, 65% of the total dredging effort has taken place in the lower 11 km of the river, between Steveston and Sand Heads (McLean et al. 2006). In 1999, the Fraser River Estuary Management Program (FREMP) began to manage dredging on the lower Fraser River to ensure that the rate of dredging was approximately in proportion to the incoming bed material load (FREMP 2005).

According to FREMP (2006), frequent maintenance dredging of the navigation channel occurs at the mouth of the river, especially in Steveston Cut. There is also infrequent dredging of secondary channels in Ladner Reach and Sea Reach to maintain depths for navigation of small vessels. Further upstream, between the New Westminster trifurcation (where the North Arm and South Arm diverge) and Deas Island, annual maintenance dredging occurs at St. Mungo's Bend and Annieville Channel (**Figure 2-1**) near the Fraser-Surrey Docks to allow access for large ship traffic. Transfer pits are also present near Tilbury Island, from which sand is pumped to upland sites. Infrequent (no more than once every five years) localized dredging for boat access to small craft harbours in Ladner and Steveston also takes place.

During the height of dredging activity from 1976 to 1990, about 15% of the total annual sediment removal was from the reaches adjacent to the Tunnel: Gravesend Reach upstream and Woodward Reach downstream (**Figure 4-8**). At Gravesend Reach, large-scale borrow dredging had a noticeable effect on bed levels. Bed levels remained relatively constant when the dredging quantities remained in the order of 200,000 m³/year, but when navigation and borrow dredging reached up to 700,000 m³/year during the 1980s, the bed at Gravesend lowered at a rate of about 25 cm/year (NHC 2002a). Although total removals have rebounded since 2001, less than one per cent of total dredging has been extracted from Gravesend Reach annually.

Since 2004, the maximum vessel draft in the reaches downstream of Deas Island (Woodward Reach, Ladner Reach, Sea Reach, Canoe Passage, Steveston Cut, and Sand Heads Reach) has been increased from 10.7 m, which had been in place since 1976, to 11.5 m.

Figure 4-8 Annual Dredging Effort on the Lower Fraser River from 1960 to 2012.

5.0 Fluvial Processes and Morphology

5.1 Long-Term Lateral Changes

The Fraser River estuary has historically been morphologically active. The river transports large volumes of sand downstream of Mission, at which point patterns of deposition, mobilization and transport become heavily influenced by the tides. As a result, the configuration of channels at the mouth of the river is complex and, in the absence of human intervention, would be in constant flux.

As late as 1898, Ladner Reach was considerably larger than its current size. Around 1827, the main channel occupied Ladner Reach, and continued along Sea Reach to the mouth. Prior to this, the main flow path may have been down Canoe Passage via Ladner Reach. The Ladner Reach entrance was observed to have widened (see **Section 5.1**), and the thalweg migrated from the right (north) to left (south) bank⁴ at Deas Island (see **Section 5.2**) in the years prior to Tunnel construction (Pretious and Thorne 1953).

Historical aerial photographs were acquired of the LAA from the University of British Columbia (UBC) aerial photograph library for nine years to represent the period from 1938 to 2009 (i.e., 1938, 1949, 1954, 1963, 1974, 1984, 1991, 2002, and 2009). Photos of the vicinity of the Tunnel (two kilometres upstream and downstream) for these years were scanned and rectified (**Attachment B**). In the broader reach extending from Tilbury Island to the mouth of the river, photos from 1949, 1974, and 2009 were scanned and rectified (**Attachment B**).

The photos reflect increasing anthropogenic development in the lower Fraser River over time, both within the river itself and on its floodplain. Banklines of the main channel were digitized from the 1974 photos and displayed on orthorectified photos from 1949 and 2009 for comparison (**Figure 5-1**). Varying tides and Fraser River flows at the time of photo collection can confound interpretation and make quantitative assessments of bank changes difficult. However, the results indicate that there has been no major shifting in the bankline position over the 60-year period. The only distinguishable changes are attributed to the dredging of the Deas Dock and some expansion of industrial water lots in the Steveston area. Banklines are generally stable, due in large part to bank hardening and river training works fixing their position.

⁴ From the perspective of an observer looking downstream.

Banklines of mid-channel islands, particularly those in the area bounded by the main channel, Ladner Reach and Sea Reach, are largely unprotected, and therefore more likely to change over time. Although they could not be reliably digitized due to the tidal variations between photos (1949 photos were collected at higher tide than 2009 photos), a visual comparison of the photos in **Figure 5-1** suggests that existing islands have expanded since 1949. In particular, Little Hart Island developed between 1949 and 1974 and has been attributed to dredge spoil dumping and subsequent transport by currents (Hay & Company Consultants Inc. 2010). Little Hart Island's growth appears to have forced the flow at the elbow of Ladner Reach north, into Barber Island. The main channel of the reach has since shifted north of Little Hart and Big Hart islands, while the south channel has become constricted.

Downstream in Sea Reach, the width of the southern portion of the channel has not changed appreciably, but the reach downstream of the confluence with Woodward Slough appears to have widened between 1949 and 2009.

A sand bar located approximately 1.5 km upstream of the Tunnel, at the downstream end of Tilbury Island, was first observed in the 1954 air photo. Favourable tides allowed observation of it again in the 1984 photoset, by which time it had started to become colonized by vegetation. Known as Tilbury Marsh, the bar is still present and is roughly three-quarters colonized by marsh vegetation. Nonetheless it represents a relatively young geomorphologic feature.

Archived UBC reports for the Fraser River model show that between 1898 and 1953, the upstream end of the Kirkland Island was subject to considerable erosion (Pretious and Thorne 1953). The bankline at the downstream end of Deas Island also receded, with the majority of the change occurring between 1948 and 1953. Air photos from this year onwards suggest that the banklines of upstream Kirkland Island Deas Marsh have largely stabilized.

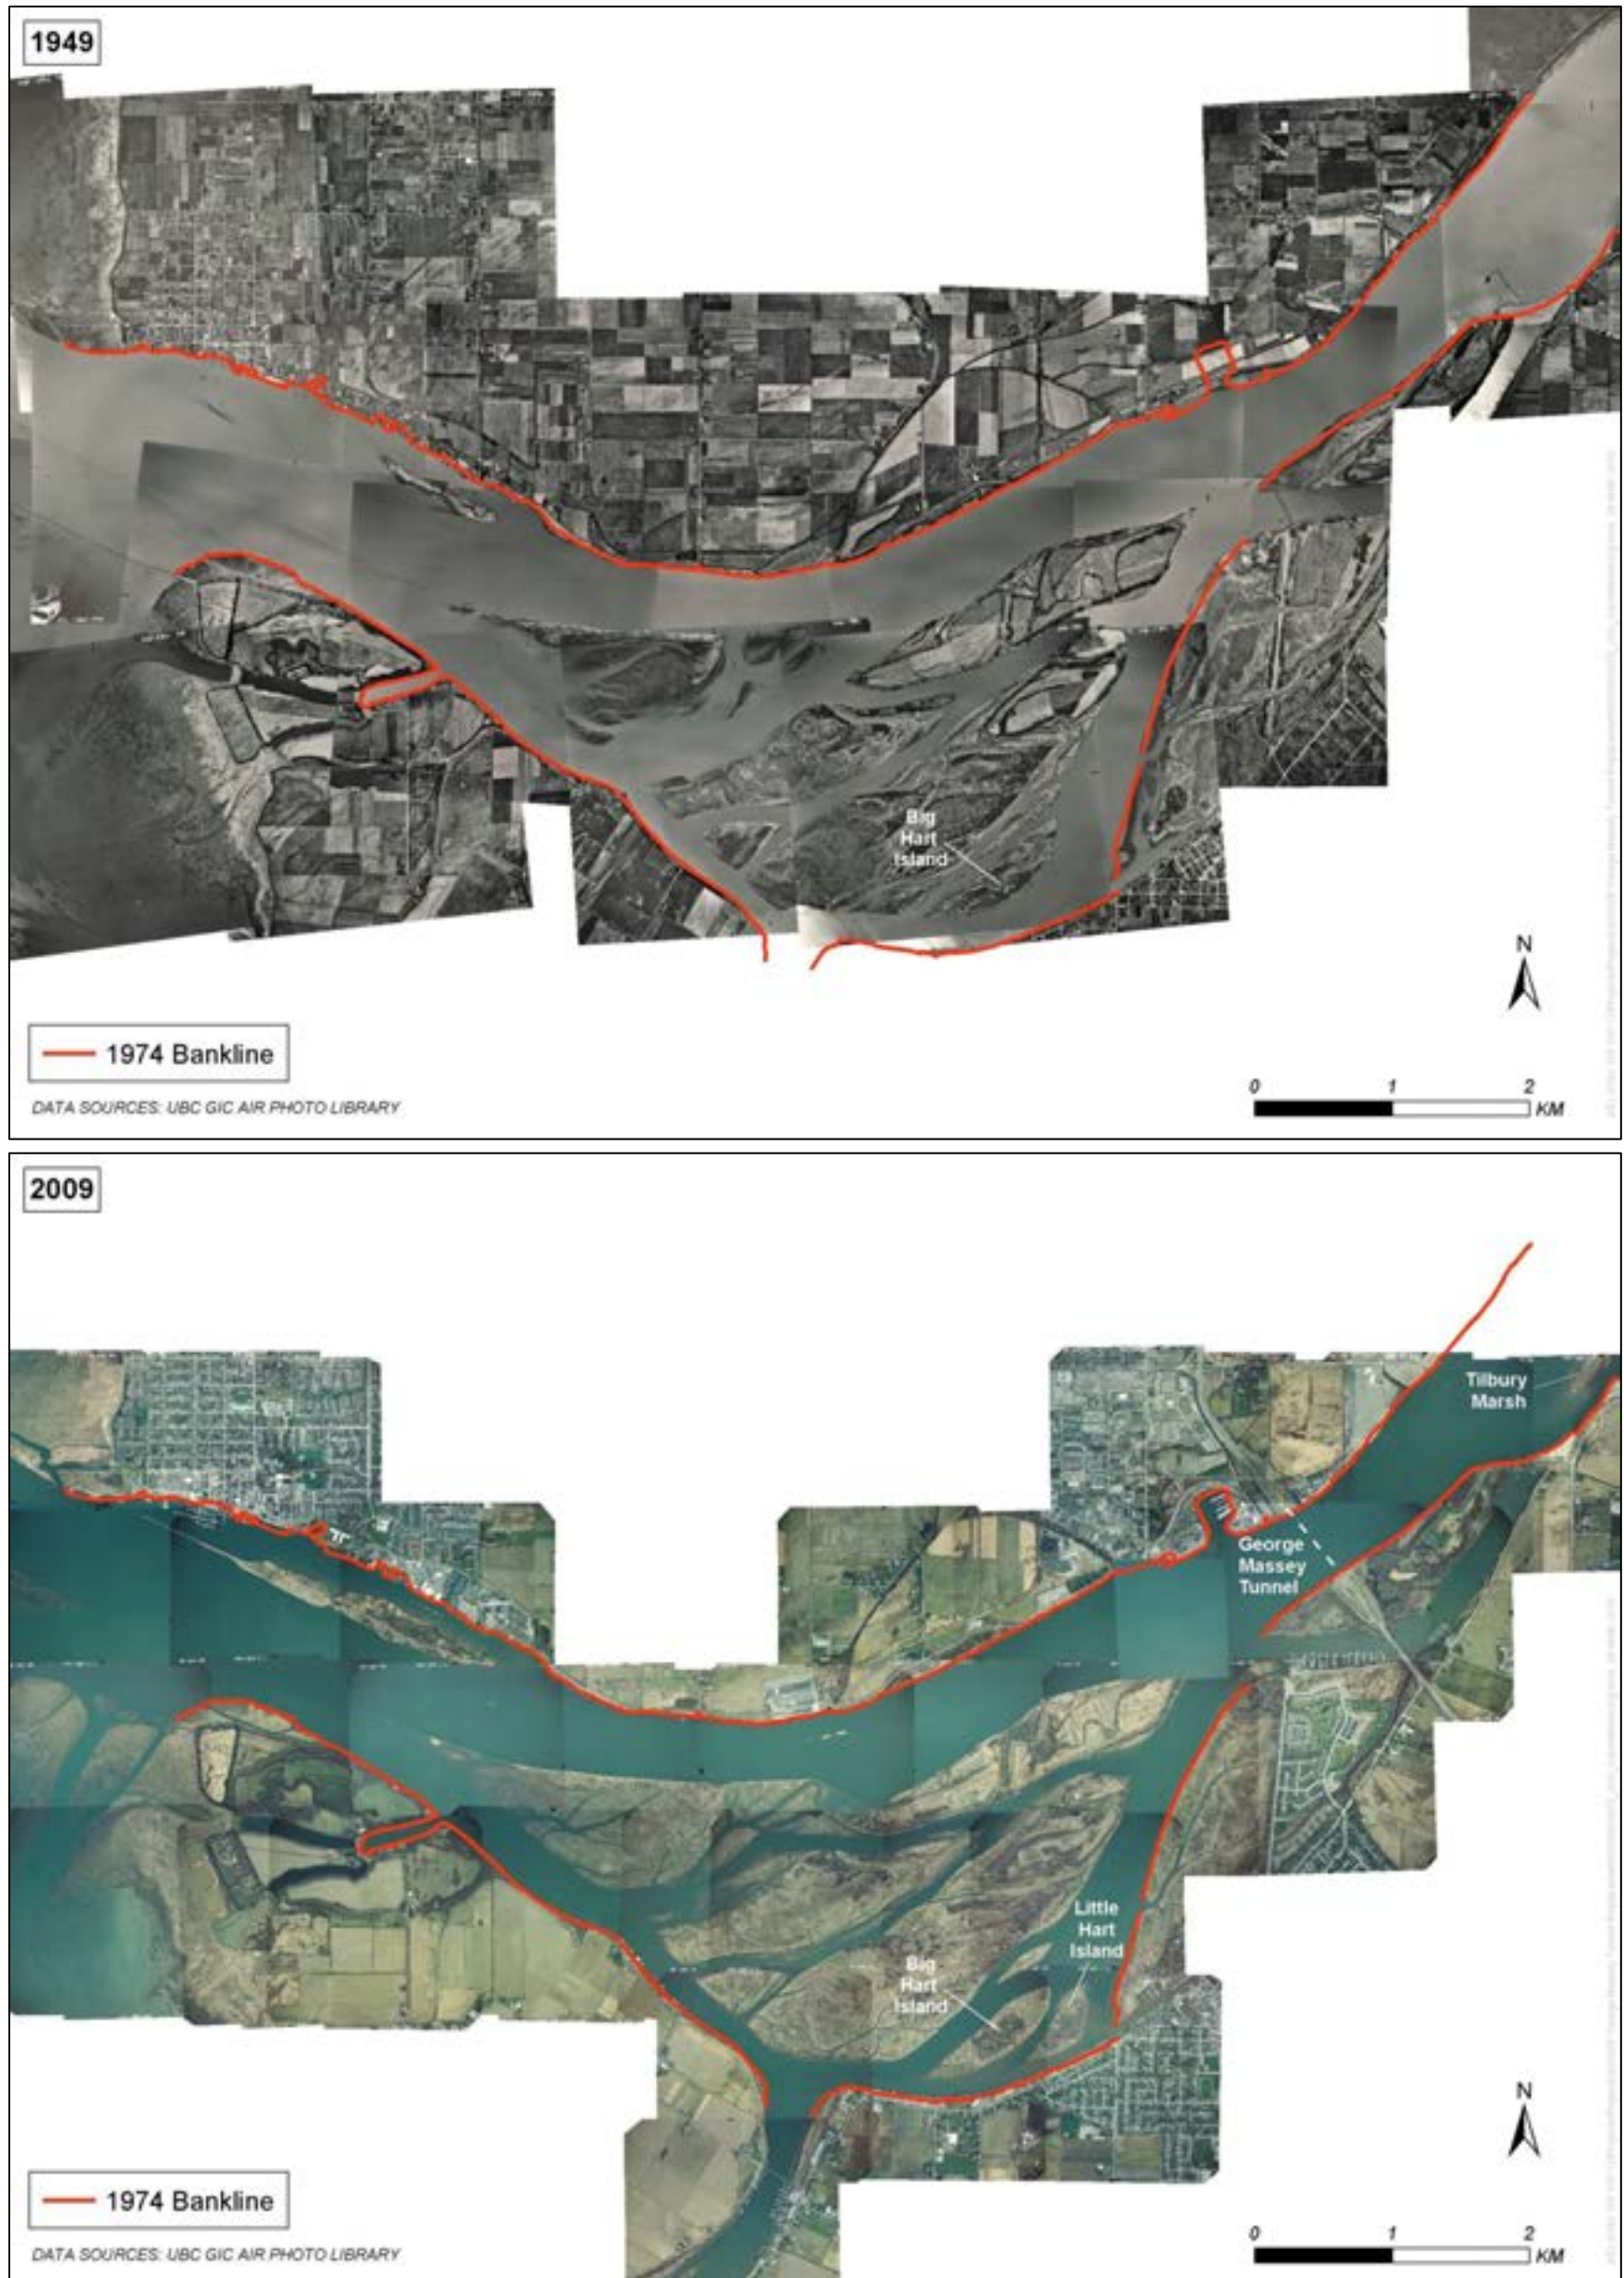

Figure 5-1 Historical aerial photographs comparison of the study reach between 1949 and 2009. Red line represents the digitized banklines from 1974. Tide heights during photo collection: 1949 = 0.6 m, 1974 = 0.0 m, 2009 = 0.0 m.

5.2 Long-Term Vertical Changes

Changes in riverbed elevations along the study reach were assessed using historical bathymetry from PWGSC. Annual datasets were available from 1988/89 through 2014 and from a more recent period than the air photos. To assess changes in bed elevations, survey data collected during the winter low-flow period for the years 1988/89, 2000/01, 2008/09 and 2014 were reviewed. Whereas the data from 1988/89 consist of surveyed cross-sections collected every 100 m, data from the 2000s consist of multibeam surveys (data point every metre) with some supplementary single-beam survey transects. Coverage along the study reach is very good, with some small gaps in in 1988/89⁵ and 2014⁶. Triangulated Irregular Network (TIN) surfaces were generated for each year using the point data. Longitudinal profiles along the thalweg between the Port Mann Bridge and the river mouth were extracted from each of the surfaces as well as cross-section profiles in the same reach.

The longitudinal profile downstream of the Port Mann Bridge is characterized by deep pools separated by shallower reaches (**Figure 5-2**). The pools occur at channel bends, narrower sections, and at instream structures such as bridge piers and pipeline and water main crossings where channel morphology has been constrained. Notably, a 15-m scour hole has developed in the long profile downstream of the Alex Fraser Bridge since 1988/89. The Tunnel is higher than the adjacent channel within about two kilometres upstream and downstream (**Figure 5-3**), but remains lower in elevation than Woodward Reach and Steveston Cut, which are further downstream.

Cross-sections from three well-spaced locations (**Figure 2-1**) along the lower 35 km length of the river (upstream of the New Westminster trifurcation, at Tilbury Island, and at Woodward Reach) are shown in **Figure 5-4 a, b, and c**. A review of these cross-sections suggest that the highest bed elevations were in 1988/89, with the bed lowering by 1.5 to 3.5 m as of 2014. At Tilbury Island, where there is a bend in the channel, scour has been greater along the outer right bank. About seven kilometres downstream from the bend, where there are a number of training works (**Figure 4-7**), concentrated flow at Woodward reach has deepened the channel near the right bank, and deposition has taken place at the opposite bank.

⁵ Missing data include the upstream portion of Ladner Reach and a section between Annacis Island and Tilbury Island.

⁶ Survey data from Ladner Reach were not available at the time of analysis.

The long profile in **Figure 5-2** also shows there has been a trend towards general bed lowering over much of the 45-km river profile downstream of Port Mann Bridge. The amount of lowering between 1988/89 and 2014 is consistent with that observed at individual cross-sections and corresponds to an average annual rate of approximately 10 cm/year. These changes are more recent but the trend toward bed lowering is consistent with previous findings of long-term riverbed degradation downstream of New Westminster. Between 1951 and 1988, the channel bed lowered by two to three metres (NHC 2002*b*). McLean et al. (2006) noted that the greatest lowering occurred in the 1980s, which corresponds to the period during which sediment removal volumes were consistently greater than incoming bed material load. They further observed that, since the 1990s, this trend has slowed with the reduction in dredging volumes, but anticipated that the river would continue to undergo changes resulting from earlier intensive dredging for at least the subsequent two decades. Since 2004, dredging volumes have increased in the lower reaches to facilitate an increase in vessel draft. It is expected that progressive degradation migrating up to New Westminster will resume in response to the increased dredging.

Figure 5-2 Historical Longitudinal Profiles for the Lower Fraser River (Data Source: Public Works and Government Services Canada 2014)

Figure 5-3 Historical Longitudinal Profiles for the Lower Fraser River in the Vicinity of the Tunnel (Data Source: Public Works and Government Services Canada 2014)

A comparison of historic cross-section bathymetry surveyed over time at Tilbury water main and Lulu Island–Delta water main (**Figure 5-5**), located upstream and downstream of the Tunnel respectively, provide further validation of the bed lowering trend. At the Lulu Island–Delta water main crossing, the bed scoured by as much as 2.5 m between 1981 and 1997. Scour protection was added in 2000, and the bed is noticeably higher in the 2011 profile. Scour of 0.5 to 1.0 m occurred again between 2011 and 2013. Prior to construction of the Tunnel, cross-sections surveyed near the water main between 1947 to 1952 indicate that there was approximately 2.5 to 3.5 m of bed elevation change there, largely attributed to shifting of the thalweg from the right to left bank by a strong shoal that formed on the right side of the channel during the 1950 freshet (Pretious and Thorne 1953).

At the Tilbury water main crossing, the bed scoured down by 2.5 to 3 m between 1990 and 1997. As a result of scour protection being added in 2001/2002, the profile is higher in 2008 than in 1997. From 2002 to 2008, only about 0.5 m of scour is observed at this crossing.

Figure 5-4 Comparison of River Cross-sections (a) Upstream of New Westminster Trifurcation (km 34.5), (b) Tilbury Island (km 22.8), and (c) Woodward Reach (km 16) Extracted from Historical Bathymetric Surveys

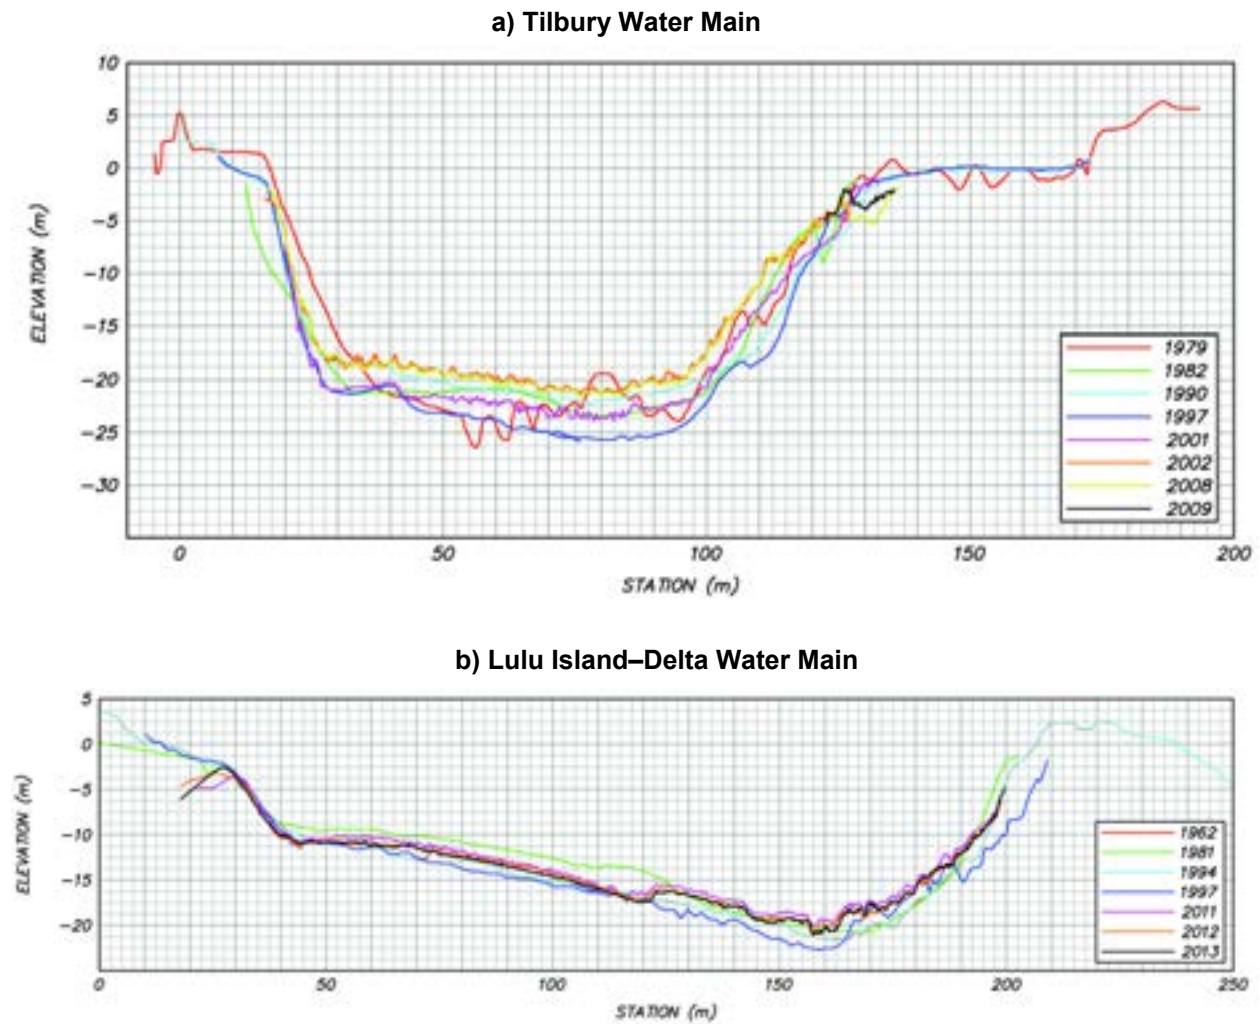

Figure 5-5 Comparison of Cross-sections Profiles from Historical Surveys at a) Tilbury Water Main and b) Lulu Island–Delta Water Main

Figure 5-6 shows the bed level changes in the vicinity of the Tunnel over three time periods: (a) 1988/89 to 2000/01, (b) 2000/01 to 2008/09, and (c) 2008/09 to 2014. The 1988/89 to 2000/01 period overlaps with peak dredging activity, with the post-2001/02 period corresponds to minimal dredging. Nonetheless, the observed trends inherently comprise both natural scour and deposition, and dredging, as the river responds over time to this disturbance.

The greatest bed level changes seem to have occurred in the 11-year period between 1988/89 and 2000/01. Upstream of the Tunnel, the main channel side of Deas Dam underwent about two to four metres of local deposition over that period. On the main channel side of Deas Island, a zone of significant scour (more than three to four metres) developed during the same time frame, with half that amount of bed lowering from 2000/01 to 2008/09. For both these areas, there is inadequate information for a 2008 to 2014 comparison.

Downstream of the Tunnel, the thalweg impinges on the left bank to the upstream third of Kirkland Island and there is evidence of scour along this bank. Between the Tunnel and the Lulu Island–Delta water main, there is a hole at the left bank that was scoured by four metres between 1988 and 2000, and lesser amounts in subsequent intervals; corresponding deposition occurred immediately downstream of the scour hole.

Further downstream at the Kirkland Island bifurcation, local erosion and deposition of greater than three metres has taken place in all three periods, likely due to how the rock spur divides flow into the two channels differently with varying seasonal discharges. An accumulation of sediment deposited in the mid-channel off Kirkland Island in the 1988/89 to 2008/09 period was presumably sourced from sediment eroding along the left bank upstream of the Tunnel. A summary comparison of bed elevation changes between 1988/89 and 2008 is provided in **Figure 5-7**. There is inadequate survey data to allow a 2008 to 2014 comparison.

Due to sparse survey coverage within the side channels, Ladner Reach could only be assessed for two time periods, from 1988/89 to 2000/01 for lower Ladner Reach, and from 2000/01 to 2008/09 for the entire reach. Bed level changes in Ladner Reach appear to be modest, with less than one metre of scour along the thalweg, and deposition of the same magnitude near adjacent banks. Detection of changes may, however, be confounded by dredging activity. There are localized areas of greater scour at the upstream and downstream ends of the islands, and where the thalweg impinges on the bank. Local deposition of two to three metres between 2000/01 and 2008/09 was also observed in Ladner Harbour, which was slated for dredging in 2014.

Historical bathymetric charts from the Department of Public Works (the predecessor of PWGSC) supplement the understanding of more recent bed changes—specifically, those from 1950, 1967, and 1983. The shift in primary flow to north of Big Hart Island (**Figure 5-1**) deepened the channel there from a shoal in 1950 to five to seven metres in 1967, and increased sedimentation south of Big and Little Hart islands reduced depths from seven to eight metres in 1967 to 2.5 to 5.5 metres in 1983. The bed in the reach between Kirkland Island and Big and Little Hart islands did not change appreciably between 1950 and 1983. Further downstream, in Sea Reach, sedimentation has occurred downstream of the Woodward Slough confluence, with bathymetric charts showing maximum depths of nine metres in 1967 and seven metres in 1983.

Figure 5-6 Change in Fraser River Bed Elevations in the Vicinity of George Massey Tunnel Between Survey Periods (a) 1988/89 – 2000/01, (b) 2000/01 – 2008/09, and (c) 2008/09 - 2014.⁷

⁷ Some Gaps Occur in the Survey Datasets in Secondary Channels.

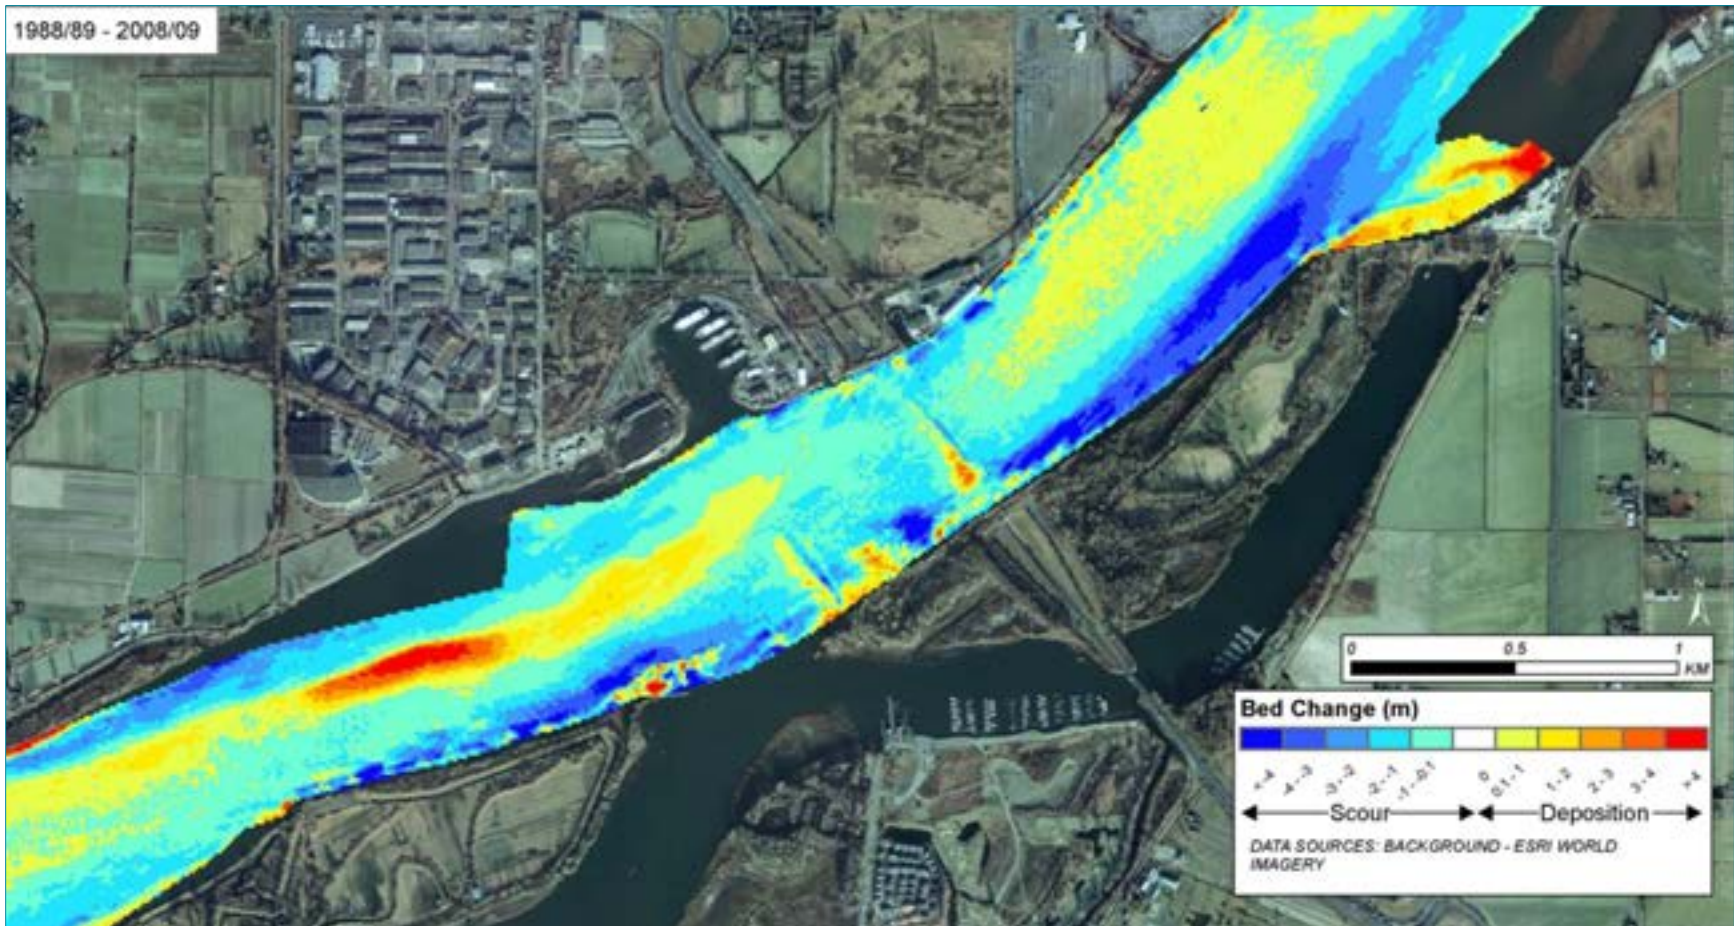

Figure 5-7 Trench Morphology and Evolution

5.3 Project Considerations

The study assumes at least four of six Tunnel segments are to be removed (**Section 3.1**). Tunnel removal will result in a trench feature in the river bed. It is particularly instructive to review trench evolution in comparison with the evolution of a dredge cut, since dredge cuts are common in the reaches of interest in this study, and their effects are relatively well known.

Whereas a dredge cut typically spans a number of kilometres, a trench tends to be more confined, extending for a few hundred metres along the river profile. The larger footprint of a dredge cut has the ability to locally lower the water surface profile. The water draft at the edges in particular is reduced and flow velocities increase locally as a consequence. The knickpoint created in the profile can therefore headcut upstream and deposit the eroded material immediately downstream at the toe of the slope. A similar knickpoint migration occurs at the downstream end, except that it travels downstream and there is no deposition at the toe of the slope. The transition between the cut slopes and the bottom become more gradual over time, thereby altering the overall morphology.

In contrast, the narrower trench feature proposed for the Project of approximately 95 m wide and 8 m deep (**Attachment A** and **Figure 3-2**), would not have as considerable an effect on the height of the water surface profile. For a river slope of 0.00005 (similar to the lower Fraser River near the Tunnel), a 100-m wide trench would result in an approximate 0.5% change in water level. This minimal water level change translates to less acceleration of flow; therefore, no erosion of the upstream knickpoint would occur and the trench would fill. However, the downstream knickpoint, would erode and propagate downstream.

Walstra et al. (1999) modelled the morphological development of trench geometries over 50 years and found that narrow, relatively deep trenches, such as anticipated for the Project, are preferable over wide, relatively shallow ones if stability (i.e., minimum migration rate) is desirable. That study did show, however, that deep trenches have a longer morphological lifespan (time to fill) than wide trenches (Walstra et al. 1999). The volume required to fill a trench with dimensions for the full Tunnel removal option is on the order of 260,000 m³, which represents about nine per cent of the average annual bed material load of the Fraser River (2.9 million m³). In addition, compared with the seven million cubic metres (or more) dredged from the Fraser River in a single year at the height of dredging activity, or the one million cubic metres removed in the local reaches annually, the excavated trench volume of 260,000 m³ constitutes a small fraction.

Trenches have been excavated for other river infrastructure developments on the Fraser River. In 2009, a 200-m-wide by 5-m-deep by 300-m-long trench was excavated to allow barge access for construction of the Port Mann Bridge. Numerical modelling (NHC 2009) indicated that the 100,000 m³ trench would infill by 45% in about a year, with complete filling in three years. Subsequent monitoring verified that filling has occurred, although the actual time required for infilling is not known. In another example, an excavation site on the Fraser River at Bedford Channel was dredged in early 2006. The trench had similar characteristics to the excavated area at Port Mann, and underwent about 100,000 m³ of sediment infilling after two freshets.

6.0 Modelling Methodology

Hydraulic and morphodynamic numerical modelling analyses were conducted to evaluate potential changes in river hydraulics (i.e., current distributions and water levels), and morphology (i.e., sedimentation patterns) associated with the full Tunnel removal and partial Tunnel removal proposed options. Modelling used the TELEMAC system, a suite of finite element computer programs developed by the Laboratoire National d'Hydraulique et Environnement (LNHE). The TELEMAC system is a modelling tool recognized throughout the world, having more than 4,000 registered users including BC Hydro, Hydro-Québec, and Canadian Coast Guard, as well as universities, engineering schools and research centres. TELEMAC programs utilized for this study include the following:

- TELEMAC3D – A three-dimensional hydrodynamic model that solves the time-dependent Navier-Stokes equations with an evolving free surface, under the assumption of hydrostatic or non-hydrostatic pressure distribution using the finite element method.
- SISYPHE – A sediment transport and morphodynamic model that computes bed-load and suspended load separately, and the resulting bed changes using the Exner equation.

The modelling methodology and results are presented in the sections below. Further details on the development, calibration, and validation of the numerical models can be found in **Attachment C**.

6.1 Far-Field and Near-Field Models

As described in **Section 2.1** and shown in **Figure 2-3**, the RAA for this study extends from the mouth of the Fraser River to New Westminster. Modelling this extent of the river while providing a useful level of detail at the Project site required careful consideration of model size and computational time. To yield the desired combination of model precision and efficiency, two TELEMAC models were developed for the study:

Far-Field: the Strait of Georgia/Lower Fraser River (SOG/LFR) model extends from Ballenas Island at its northern boundary, to Port Renfrew at its western boundary (**Figure 6-1**). This model mesh also includes the Fraser River up to km 42, downstream of Port Mann Bridge. The SOG/LFR model was used to evaluate far-field changes to hydraulics and sedimentation associated with the proposed Tunnel removal options.

Near-Field: the No.5 Road model extends from 1,300 m upstream of the Tunnel to 700 m downstream of the Tunnel (**Figure 6-2**). The No.5 Road model was used to evaluate near-field hydraulic and sedimentation associated with the proposed Tunnel removal options. This spatial resolution was employed to better define Tunnel geometry, and hence, better identify features in the flow field that could result in changes to the local deposition pattern.

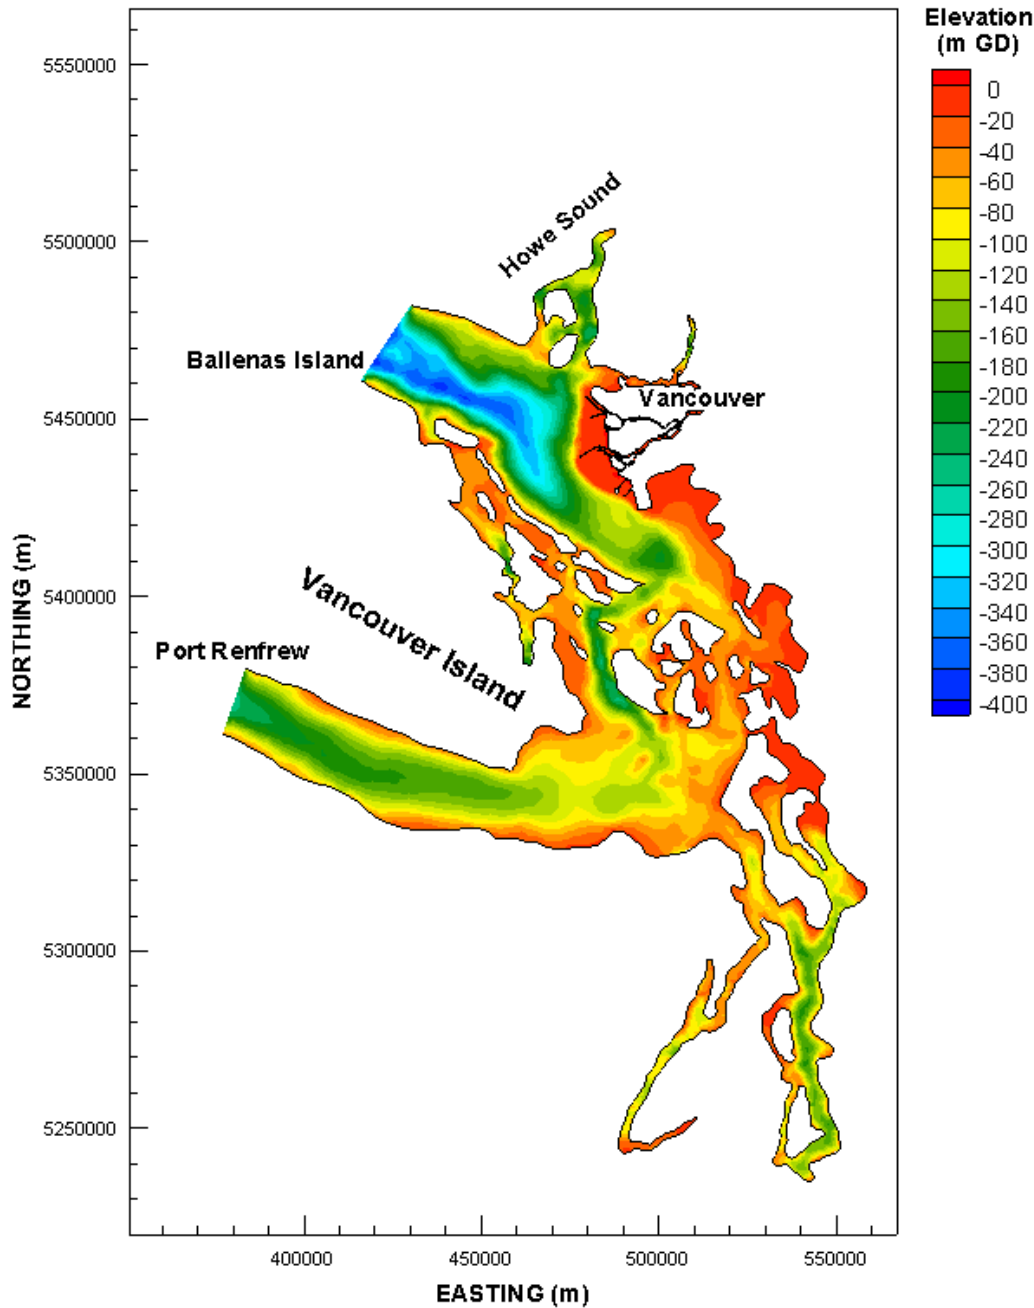

Figure 6-1 TELEMAC Strait of Georgia/Lower Fraser River (Far-Field) Model Extent

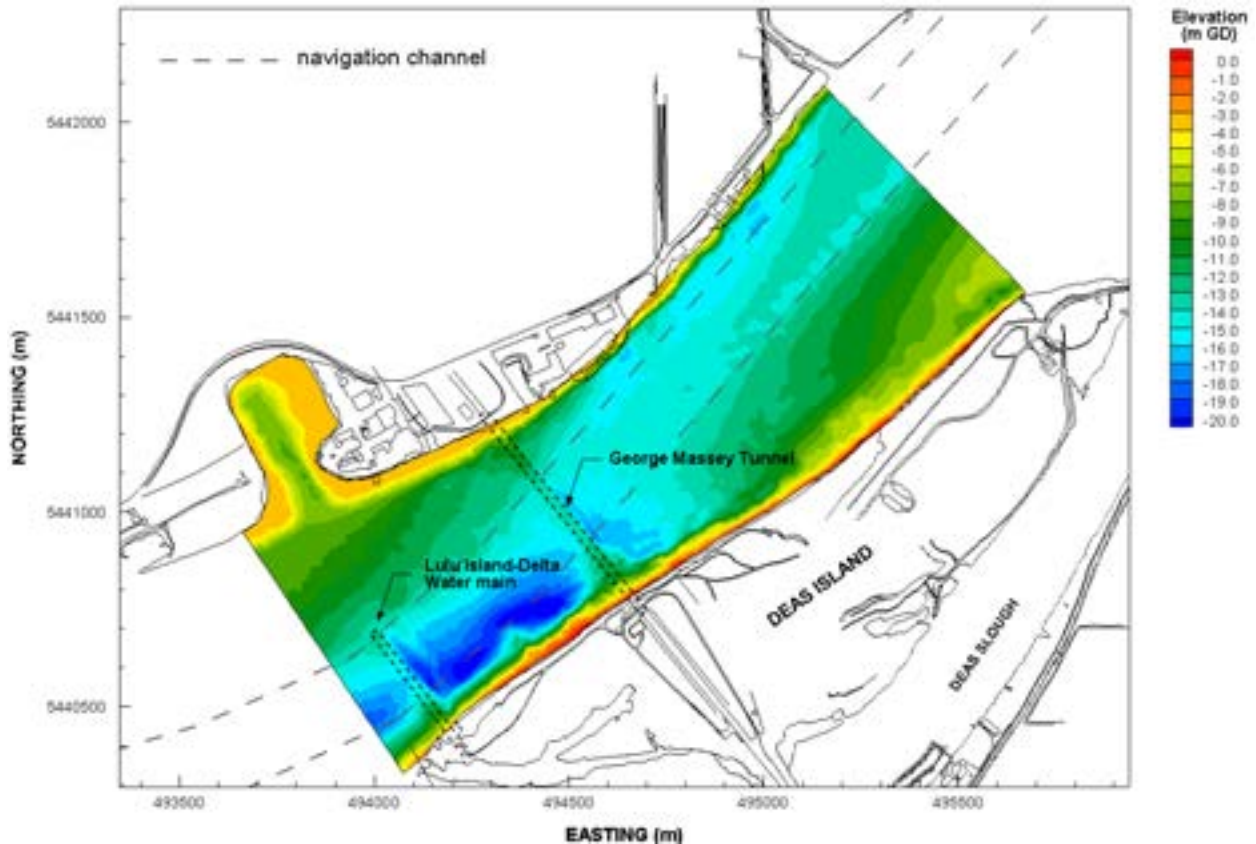

Figure 6-2 TELEMAC No.5 Road (Near-Field) Model Extent

The SOG/LFR model is used to evaluate far-field hydraulic effects and sedimentation associated with the proposed Tunnel removal options. The TELEMAC model uses a computational mesh as a mathematical representation of the physical environment under study. A mesh typically includes information on the shoreline geometry, the bathymetric features, and the bottom-type characteristics of the area involved. The SOG/LFR model mesh comprises approximately 35,000 nodes, 63,000 elements, and 10 levels in the vertical. The element lengths vary from approximately 3,000 m in the Strait of Georgia to about 50 m in the lower Fraser River. In the river reach near the Tunnel, the element lengths were further refined to about 30 m.

The No.5 Road model is used to evaluate near-field hydraulic and sedimentation associated with the proposed Tunnel removal options. This model mesh comprises approximately 11,000 nodes, 21,000 elements, and 10 levels in the vertical. The element lengths vary from approximately 20 m in the upstream to about 5 m in the vicinity of the Tunnel. This spatial resolution was employed to better define Tunnel geometry, and hence, better identify features in the flow field that could result in changes to the local deposition pattern.

To ensure that both models were subjected to the same hydraulic conditions, the modelled flow and water levels from the SOG/LFR model at km 18 and km 19 (near the Tunnel) of the Fraser River were compared against the same values in the No.5 Road model and found to have good agreement (**Figure 6-3**).

Figure 6-3 Comparison of Modelled Water Levels at Deas Island for the Strait of Georgia/Lower Fraser River and No.5 Road Model Meshes During Peak of 2012 Freshet

6.2 Modelled Scenarios

The model analysis was conducted for two distinct scenarios:

1. The trench infilling scenario examines the short-term channel response to the removal of the Tunnel, particularly trench migration and infilling. Key processes analyzed include: (a) trench migration and infilling as a result of Tunnel removal, and (b) the potential changes on nearby infrastructure and habitat due to the trench.
2. The post-infilling scenario examines the potential changes to the river hydraulics and sedimentation patterns as a result of Tunnel removal, after the trench has been filled in by deposition of river sediments. To reduce computation time and more clearly delineate the short-term and long-term analyses, river bathymetry at the Tunnel alignment was modified to blend with upstream and downstream bed elevations, rather than beginning with the final bed configuration of the trench infilling model.

6.3 Model Geometry

Five model geometries were developed for the analysis:

- Existing conditions
- Full Tunnel removal trench infilling
- Full Tunnel removal post-infilling
- Partial Tunnel removal trench infilling
- Partial Tunnel removal post-infilling

These geometries represent the initial bed profile for each model simulation. Each of these is described below.

6.3.1 Existing Conditions

Existing channel geometry for both the SOG/LFR and No.5 Road models was derived using the following datasets:

- Bathymetric survey data collected by CRA Canada Survey Ltd. on April 2, 2014. The survey extended approximately 500 m upstream and downstream of the Tunnel (**Figure 3-3**).
- For the Fraser River, data from the 2014 PWGSC bathymetric surveys and 2005 Fraser Basin Council LiDAR acquisitions
- For Puget Sound, the Strait of Georgia and Juan de Fuca Strait, CHS bathymetry data

No.5 Road model geometry for existing conditions (with the Tunnel) is shown in **Figure 6-4**.

Figure 6-4 No.5 Road Model Geometry for Existing Conditions (with the Tunnel)

6.3.2 Full Tunnel and Partial Tunnel Removal Geometries

To determine the extent of excavation for the full Tunnel and partial Tunnel removal geometries, the as-built drawings prepared for the B.C. Toll Highways and Bridges Authority (**Attachment A**) were reviewed and a three-dimensional model of the Tunnel and surrounding erosion protection was developed using computer-aided design (CAD). The CAD model was then used to develop localized digital elevation models (DEMs) within the extents of the excavation for the Tunnel removal options. Beyond the extents of the excavation, the localized DEMs were merged with the existing conditions DEM so that all three DEMs were identical outside of the excavation area. To avoid discontinuities at the border of the merged DEMs, the extents of excavation were extended up to existing ground at a 2H:1V slope.

6.3.2.1 Full Tunnel Removal Trench Infilling

For full Tunnel removal trench infilling scenario, it was assumed that all six precast concrete segments of the Tunnel were to be removed. The two sections (TE1 and TE6) closest to the river banks are located partially under existing ground, as shown in **Figure 3-1**. Banks at the Tunnel crossing were assumed to be re-constructed and protected with riprap to match the adjacent upstream and downstream banklines. **Figure 6-5** shows the No.5 Road DEM used for the full Tunnel removal option in the trench infilling scenario. The DEM used for the SOG/LFR trench infilling scenario was identical to this in the Tunnel reach.

Figure 6-5 No.5 Road Model Geometry for Trench Infilling Scenario Modelling of the Full Tunnel Removal Option

6.3.2.2 Full Tunnel Removal Post-Infilling

The full Tunnel removal post-infilling scenario examines potential effects of Tunnel removal after sediment has filled in the trench. The DEM used for the SOG/LFR trench infilling scenario was identical to the No.5 Road DEM used for the full Tunnel removal option in the trench infilling scenario as shown in **Figure 6-6**.

6.3.2.3 Partial Tunnel Removal Trench Infilling

For the partial Tunnel removal trench infilling model, it was assumed that the four middle precast concrete segments of the Tunnel were removed, while the two end segments closest to the river banks (TE1 and TE6) and the existing banks were left intact. It was assumed that a riprap “nose” with a 2H:1V slope would be placed around the end of each end segment to avoid abrupt transitions leading to adverse hydraulics. The DEM used for the SOG/LFR model was identical to the No.5 Road model bathymetries used for partial Tunnel removal in the trench infilling model as shown in **Figure 6-7**.

Figure 6-6 No.5 Road Model Geometry for Post-infilling Scenario Modelling of the Full Tunnel Removal Option

6.3.2.4 Partial Tunnel Removal Post-Infilling

For the partial Tunnel removal post-infilling model, river bathymetry at the Tunnel alignment was modified to blend with upstream and downstream bed elevations. **Figure 6-8** shows the No.5 Road model bathymetry used for partial Tunnel removal in the post-infilling model. The DEM used for the SOG/LFR model was identical to this in the Tunnel reach.

Figure 6-7 No.5 Road Model Geometry for Trench Infilling Scenario Modelling of the Partial Tunnel Removal Option

Figure 6-8 No.5 Road Model Geometry for Post-infilling Scenario Modelling of the Partial Tunnel Removal Option

As seen in **Figure 6-5** and **Figure 6-7**, the excavation geometries for the full and partial Tunnel removal options are very similar. The two concrete sections (TE1 and TE6) closest to the river banks are located mostly under existing ground (**Figure 3-1**). For the full Tunnel removal option, it was assumed that the river banks within the extent of the excavation will be re-constructed and armoured to best match the existing river banks on either side of the excavation. After the banks are re-constructed, most of the area above sections TE1 and TE6 would be re-covered. As a result, the net removal of material and shape of the excavation for the full and partial Tunnel removal options are similar. Cross sections along the centreline of the existing Tunnel are shown for existing conditions (black line), full Tunnel removal (red line), and partial Tunnel removal (blue line) options in **Figure 6-9**.

Figure 6-9 Cross-section along the Centreline of the Tunnel and Proposed Excavation Showing Bed Elevations for Existing Conditions, Full Tunnel Removal, and Partial Tunnel Removal Options

6.4 Boundary Conditions

The SOG/LFR model is driven at its open boundaries (Ballenas Island and Port Renfrew) by tidal levels obtained using WebTide Tidal Prediction model (Department of Fisheries and Oceans 2005) based on work by Foreman et al. (2000). Inflows to the Fraser River at Port Mann Bridge (km 42) are computed using a hydraulic model of the Fraser River that uses the MIKE11 one-dimensional hydrodynamic software developed by the Danish Hydraulic Institute. The Fraser River MIKE11 model was developed by NHC for the Fraser Basin Council in 2006 (NHC 2006) and updated two years later for B.C. Ministry of Environment (NHC 2008). The No.5 Road model is driven at its upstream end (flow) and downstream end (water level) by outputs from the aforementioned Fraser River MIKE11 model.

All model simulations were conducted using the 2012 Fraser River flow and tide conditions from WSC and CHS respectively. The year 2012 was selected because of availability of data for model calibration and because freshet flow was high that year. The high freshet flow provides the condition for evaluating the upper end of the potential changes to river hydraulics and sedimentation. The 2012 Fraser River flow at Hope, where discharge is not influenced by the tidal signal, is shown in **Figure 6-10**.

Figure 6-10 2012 Fraser River Daily Flow at Hope (Retrieved from Government of Canada 2014)

Construction work associated with Tunnel removal was assumed to commence in August or September after the Fraser River flow at Hope drops below 5,000 m³/s. In accordance with the Department of Fisheries and Oceans fisheries windows, instream work in the Fraser River estuary is limited to between July 16 and February 28 downstream of the Tunnel, and between June 16 and February 28 upstream of the Tunnel (DFO 2014). However, instream construction work during the summer freshet period (May to July) is generally difficult due to high water levels and velocities. For the trench infilling analysis, the model simulation starts on August 16, 2012 and runs for 210 days. The trench infilling model assumes that Tunnel removal would be instantaneous. Actual Tunnel removal, however, will take place over several months.

For the post-infilling analysis, the model simulation extends from May 26 to July 27, 2012. This represents the time period within the freshet during which Fraser River flows at Hope were greater than 6,000 m³/s (see **Figure 6-10**), an estimated threshold for significant sediment motion in the Fraser River. The freshet period was selected because it is the period when the Fraser River is most active and when most of the sediment transport occurs.

6.5 Sediment Characteristics

The model incorporates transport of suspended bed materials as well as bed load for each scenario. Sediment sizes in the model were based on known characteristics of Fraser River bed materials. Model sediment had a D_{50} (median diameter) of 250 μm and D_{90} (90th percentile diameter) of 450 μm , based on surface samples collected by McLaren and Ren (1995) in the lower Fraser River between February 9 and April 7, 1993.

The van Rijn formula (1993) was used to compute bed load and suspended load transport. This formula distinguishes between sediment transport above or below a reference height: transport below the reference height is treated as bed load transport, and transport above the reference height is treated as suspended load. Sediment is entrained in the water column by imposing a reference concentration at the reference height, which is a function of effective roughness height, dune/ripple height, and water depth.

Equilibrium sediment concentration was prescribed at the upstream model boundary. This modelling approach allows the sediment load entering through the boundary to be near-perfectly adapted to the local flow condition, such that limited accretion or erosion would occur near the model boundary. The daily sediment load (in million cubic metres) prescribed to the SOG/LFR model over the course of the 2012 freshet period is shown in **Figure 6-11**.

Figure 6-11 SOG/LFR Modelled Daily Input Sand Load

6.6 Calibration and Validation

Model calibration is an iterative process of comparing model results to the actual physical system, and using any discrepancies between the two, along with insights gained, to improve the model. This process is repeated until model accuracy is deemed acceptable. A model that is determined to be an acceptable representation of the real physical system is considered a validated model.

In this study, the hydrodynamic and the morphodynamic components of the models were validated using observed datasets collected from within the LAA, and additional experimental data published in peer-reviewed literature. A brief discussion on model calibration and validation are presented in this section. Further details on the development, calibration, and validation of the numerical models can be found in **Attachment C**.

6.6.1 Hydrodynamics

The hydrodynamic component of the SOG/LFR model was validated by comparing the model results to the following data:

- Observed water levels at Point Atkinson, New Westminster, Steveston, Deas Island Tunnel, and Port Mann Pumping Station
- Discharge, flow split, and velocity measurements from the March 7 and March 27, 2014 ADCP surveys

Overall, the SOG/LFR model reproduced the observed characteristics of the water levels well. The tidal ranges, between the spring and neap tidal cycle, and times of high and low waters, were well reproduced. The computed results generally had slightly lower peaks and higher troughs than the observed data, depending on the tidal conditions. The model was run over a full lunar cycle to capture various tidal ranges. Agreement with the observed water levels at the Tunnel was generally within ± 0.3 m (RMS Error = 0.28 m). Note that the water level and discharge at the Tunnel are strongly influenced by tidal levels and vary rapidly as the tide rises and falls. For example, in March 2014, the observed data at Deas Island show that the water level varied as much as 0.25 m in 15 minutes.

Discharge and velocity data are important for model calibration to confirm whether the model is accurately computing the distribution of flow and to ensure the velocity distribution across the channel is well-represented. The SOG/LFR model results were compared to discharge, flow split, and velocity measurements from the March 7 and March 27, 2014 ADCP surveys. The results show that the model represents the velocity distribution across the various river channels reasonably well. However, it tends to slightly underpredict the magnitude of velocity and discharge compared to the observed data. This discrepancy is likely because the MIKE11 model, from which the upstream boundary conditions for the present model were taken, was calibrated to peak flow conditions, whereas the ADCP measurements were taken during a low freshwater discharge. While the SOG/LFR model slightly underpredicts discharge and velocity compared to the observed values, it does accurately predict the distribution of flow, as a percentage, between the distributary channels near the mouth of the Fraser River. Therefore, the slight underprediction of velocity magnitude and discharge should not limit the utility of the model in comparing existing and proposed conditions.

6.6.2 Morphodynamics

Following the hydrodynamic model validation, the coupled hydrodynamic-morphodynamic model results were compared to experimental results and field data to validate the morphodynamic component of the models. Model validation was divided into two parts. The first part was to demonstrate the ability of the model to predict the migration and infilling of a trench. The modelled results were compared to experimental data from van Rijn (1986). The migration and infilling of the trench, resulting from the Tunnel removal, is one of the key morphodynamic processes present in the LAA. Therefore, the accurate prediction of the trench migration is important in evaluating potential changes due to the Project. The second part of the morphodynamic model validation was to compare the modelled results to measured sediment loads and sedimentation patterns on the lower Fraser River.

Comparison with flume experiments conducted by van Rijn (1986) showed that the model accurately reproduced the trench migration and infilling processes. Van Rijn's experiments observed trench migration and infilling over a range of trench geometries, each of which was well-represented by the model. This demonstrates the robustness of the model and suggests that it can be applied to problems with a range of geometries. The trench resulting from Tunnel removal is expected to have initial side slopes within the range of geometries modelled in this part of the validation. The estimated sediment grain size on the Fraser River is similar to that used in the experiments conducted by van Rijn (1986). While these flume experiments are not necessarily representative of the field conditions in the LAA, the validation shows that the model is in agreement with the theoretical understanding of how an alluvial channel will respond to an excavated trench.

In the second part of the morphodynamic model validation, the model results were compared to observations from the LAA, namely, sediment loads and sedimentation patterns on the lower Fraser River. The model predicted a total sediment input of 15 million tonnes over the 2012 freshet. This estimate falls between the 12.3 million to 31.0 million tonnes/year range estimated by Milliman (1980). The model was run over the 2012 freshet; the modelled sedimentation patterns matched reasonably with the established sedimentation patterns in the lower Fraser River, including the following results:

- Shoaling in the navigation channel in Sand Heads Reach between km 2 and km 4
- Shoaling on the south side of the navigation channel in Sand Heads Reach between km 4 and km 5
- Scour in the Steveston Jetty bend between km 5 and km 7
- Deposition along Steveston Cut between km 7 and km 12

- Scour along Kirkland Island between km 13 and km 14
- Deposition on the outer bend of St. Mungo's Bend between km 27 and km 30
- Deposition at the Fraser Surrey Dock (km 33)

The model morphodynamics were further validated by comparing Port of Vancouver maintenance dredging records with model prediction of the required dredge volumes to meet Port of Vancouver draft requirements. Required maintenance dredging volume was computed by comparing the bed surface elevation at the end of the model simulation to the dredge design grade. In general, the modelled maintenance dredging volumes compared well with the volumes recorded between 2006 and 2012 (**Attachment C: Section 3.1.5.3**).

Overall, the model has demonstrated the ability to replicate the general sedimentation pattern, and to hindcast the annual maintenance dredging in the lower Fraser River, and can be used to evaluate the relative hydraulic and sedimentation changes resulting from the proposed Tunnel decommissioning options.

6.7 Salt Wedge

Salinity was not incorporated in the model analyses; thus, the potential effect of the salt wedge on sediment dynamics (see **Section 4.1.3**) is not represented. However, this is not expected to have a significant effect on model morphodynamics because approximately 80% of sediment discharge in the Fraser River occurs during freshet (Milliman 1980), when the salt wedge is forced to the mouth of the river. The relationship between discharge and sediment load can be better visualized in **Figure 6-12**.

Figure 6-12 Mean daily Discharge and Daily Suspended Sediment Load for the Fraser River at Mission during 1985 (Retrieved from Kostaschuk and Luternauer 1989).

Studies by Ward (1976) and Villard and Church (2003) stated that the salt wedge rarely extends farther than Steveston Bend when the Fraser River flow is greater than $5,000 \text{ m}^3/\text{s}$. **Figure 6-13** shows the 2012 Fraser River flow at Hope and specific conductivity (a function of salinity) measured from Environment Canada Fraser River Water Quality Monitoring Station located about three kilometres upstream of the Tunnel. **Figure 6-13** shows that limited saline water was detected at the buoy when the flows were greater than $4,500 \text{ m}^3/\text{s}$.

Figure 6-13 2012 Fraser River Flow at Hope (WSC 08MF005) and Water Quality Monitoring Station (Environment Canada)

It is anticipated that the model may underestimate sediment shoaling in the lower reaches between Sand Heads and Steveston Bend where the salt wedge persists during the freshet. Since the Tunnel is approximately 10 km upstream of the Steveston Bend, this simplification is not likely to have a large influence on the modelling results during the freshet period.

During the non-freshet period, when the salt wedge could intrude over 30 km upstream of Sand Heads, the sediment load in the Fraser River is small compared to that during the freshet (**Figure 6-12**), and sediment movement is also small. Therefore, not incorporating salinity into the model analyses is not likely to have any substantial influence on the modelling results during the non-freshet period.

The riverbed profiles shown in **Figure 5-2** and **Figure 5-3** and show the Tunnel is several meters lower than the bed downstream (km 15) and upstream (km 19). Therefore, temporary lowering of the bed levels by one to three metres at the Tunnel is not likely to influence the maximum distance of salt wedge intrusion. Results of hydrodynamic modelling, as discussed in detail in **Section 16.7** of the Application, indicates that the proposed removal of the Tunnel will not affect the behaviour of the salt wedge.

7.0 Model Simulation Results

7.1 Existing Conditions during Low Flow Period

Existing conditions were modelled for the period of August 16 - November 14, 2012 (the low flow period) as a basis for comparison with the trench infilling scenario during the same time period. The results are presented below.

7.1.1 Hydrodynamics

7.1.1.1 Current Velocities

Local velocities for the existing condition near the time of maximum ebb tide on August 16, 2012 (day one of the assumed Tunnel removal work) were examined using the No.5 Road model.

Modelled surface velocities (**Figure 7-1**) were generally highest on the right side of the channel and in the zone of flow acceleration over the Tunnel. Surface velocities in the middle of the navigation channel upstream, on top of, and downstream of the Tunnel are 1.5, 1.7, and 1.6 m/s, respectively. Similar flow acceleration is also predicted over the Lulu Island–Delta water main downstream.

Closer to the river bed at -12 m GD elevation, predicted velocities (**Figure 7-2**) were highest in the zones of acceleration over the Tunnel, and downstream Lulu Island–Delta water main crossing. Upstream of the Tunnel, maximum velocities of 1.4 m/s were predicted on the right (north) side of the channel. Downstream of the Tunnel, the maximum velocity was similar in magnitude but more evenly distributed across the channel. This is probably due to a combination of bathymetric variations (the channel is deepest on the right side downstream of the Tunnel) and acceleration of near-bed flows over the sill formed by the Tunnel.

Figure 7-1 Modelled Surface Velocity Distribution under Existing Conditions, August 16, 2012.

Figure 7-2 Modelled Near-bed Velocity Distribution (elevation -12 m GD) under Existing Conditions, August 16, 2012.

7.1.1.2 Water Levels

For comparison with the far-field Tunnel removal options, hourly water levels at several locations upstream and downstream of the Tunnel (**Figure 7-3**) were extracted from the SOG/LFR model for the existing conditions on August 16, 2012. The minimum and maximum modelled water levels at these locations are summarized in **Table 7-1**.

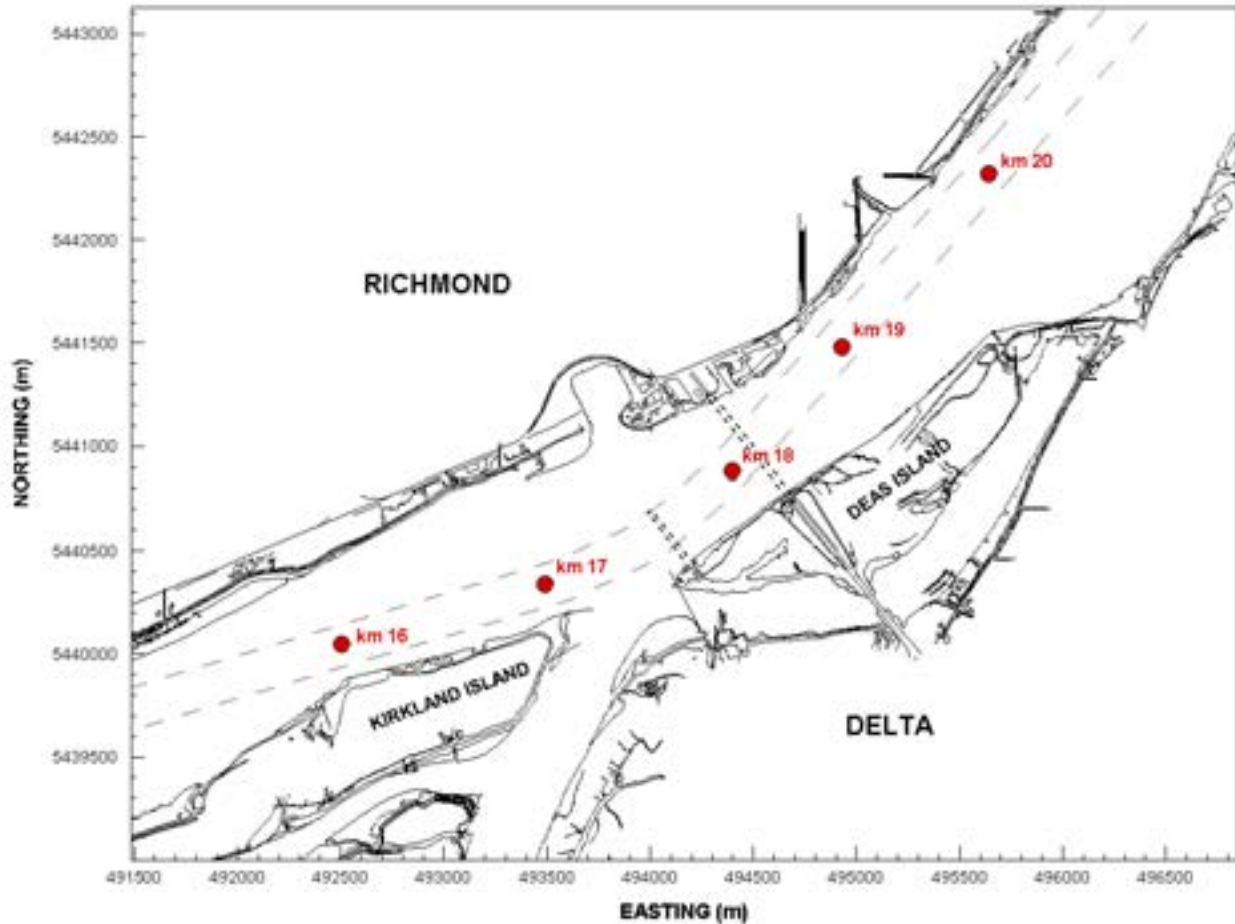

Figure 7-3 Stations Upstream and Downstream of the Tunnel where Water Level Analyses were Conducted.

Table 7-1 Modelled non-freshet water level statistics for August 16, 2012

| Station | Maximum Water Level (m GD) | Minimum Water Level (m GD) |
|---------|----------------------------|----------------------------|
| km 16 | 1.29 | -1.60 |
| km 17 | 1.30 | -1.55 |
| km 18 | 1.30 | -1.53 |
| km 19 | 1.30 | -1.50 |
| km 20 | 1.31 | -1.48 |

Near-field water levels for the existing conditions were extracted from the No.5 Road model for comparison with local water levels in the Tunnel removal options. The low-flow hydraulic analysis was based on the king tide event that occurred on December 16, 2012. The Fraser River flow at Hope on this date was 1,770 m³/s, a typical Fraser River flow during the winter period. The water level at the Tunnel during this period is shown on **Figure 7-4**.

Figure 7-4 Modelled Water Level (m GD) at the Tunnel during the Period from December 15 to 17, 2012.

Modelled current velocity distribution at maximum ebb and maximum flood conditions for June 23 and December 16, 2012 were first evaluated. The results indicate that the hydraulic condition under which Tunnel removal will likely have the greatest changes is the freshet ebb tide. Consequently, only results from the freshet ebb tide condition (i.e., 13:00 on June 23) are presented for the hydrodynamic assessment. Further details on other hydrodynamic conditions (i.e., freshet flood tide, non-freshet ebb tide, and non-freshet flood tide) are presented in **Attachment C**.

7.1.1.3 Flow Split

Flow splits between Woodward Reach and Ladner Reach were calculated from the SOG/LFR model for existing conditions at maximum ebb (at 12:00) and maximum flood (at 18:00) tides on August 16, 2012 (**Table 7-2**).

Table 7-2 Modelled Flow Splits on August 16, 2012

| Condition | Woodward Reach | Ladner Reach |
|------------------|-----------------------|---------------------|
| Ebb tide | 93% | 7% |
| Flood tide | 95% | 5% |

7.1.2 Morphodynamics

Bed evolution under existing conditions was modelled using the No.5 Road model over the period of August 16 to November 14, 2012 for comparison with the Tunnel removal options.

Figure 7-5 shows the modelled bed elevations at the end of the simulation. In general, the modelled sedimentation pattern matches reasonably with the established sedimentation patterns in this part of the lower Fraser River, including:

- Minimal deposition in the navigation channel
- Shoaling on the left bank upstream of the Tunnel
- Shoaling on the right bank downstream of the Tunnel in front of Deas Dock
- Erosion downstream of the Tunnel and the Lulu Island–Delta water main

Figure 7-5 Modelled Morphodynamic Evolution under Existing Conditions – Trench Infilling

The model predicts erosion upstream of the Tunnel and the Lulu Island–Delta water main, primarily outside of the navigation channel. From the bathymetry survey, it appears that erosion also occurs upstream of the Tunnel within the navigation channel. The model mesh size (5 m) may be too large to resolve the local hydraulic effect that induces erosion immediately upstream of these two crossings. A finer model might better reproduce this process but would require excessive computation time. The model demonstrates the ability to replicate the general sedimentation pattern and can be used to evaluate the relative hydraulic and sedimentation changes due to Tunnel removal.

7.2 Existing Conditions during Freshet

Existing conditions were modelled for the period of May 26 - July 27, 2012 (freshet) as a basis for comparison with the post-infilling scenario during the same time period. The results are described below.

7.2.1 Hydrodynamics

The freshet hydrodynamic analysis was based on a tide occurring on June 23, 2012 when the Fraser River flow at Hope was close to its peak discharge value of 13,500 m³/s.

7.2.1.1 Current Velocities

Current velocities were extracted from the No.5 Road model at maximum ebb tide, about 13:00 on June 23, 2012. Surface and near-bed velocities showed similar patterns as the low flow simulation (**Section 7.1.1**); however, currents were generally faster for the freshet. Maximum predicted surface velocities were highest on the right side of the channel and in the zone of flow acceleration over the Tunnel (**Figure 7-6**). Surface velocities in the middle of the navigation channel upstream, on top of, and downstream of the Tunnel are 2.2, 2.6, and 2.5 m/s, respectively. A similar acceleration is also predicted over the Lulu Island–Delta water main downstream of the Tunnel.

Closer to the river bed at -12 m GD elevation, predicted velocities (**Figure 7-7**) are highest in the zones of acceleration over the Tunnel and downstream of Lulu Island–Delta water crossings. Predicted velocities upstream, on top of, and downstream of the Tunnel are 1.9, 2.3, and 2.1 m/s, respectively. Upstream of the Tunnel, maximum velocities of 2.3 m/s are predicted on the right side of the channel. Downstream of the Tunnel, the maximum velocity is similar in magnitude but more evenly distributed across the channel. This is probably due to a combination of bathymetric variations (the channel is deepest on the right side downstream of the Tunnel) and acceleration of near-bed flows over the sill formed by the Tunnel.

Figure 7-6 Modelled Surface Velocity Distribution under Existing Conditions, Ebb Tide June 23, 2012.

Figure 7-7 Modelled Velocity Distribution at -12 m GD Elevation under Existing Conditions, Ebb Tide June 23, 2012.

7.2.1.2 Water Levels

For comparison with the far-field Tunnel removal options, hourly water levels at several stations upstream and downstream of the Tunnel (**Figure 7-3**) were extracted from the SOG/LFR model over the period from June 22 to June 24, 2012. The maximum and minimum modelled water levels at these stations are summarized in **Table 7-3**.

Table 7-3 Modelled Minimum and Maximum Water Levels under Existing Conditions for June 22 to June 24, 2012

| Station | Maximum Water Level (m GD) | Minimum Water Level (m GD) |
|---------|----------------------------|----------------------------|
| km 16 | 1.608 | -1.141 |
| km 17 | 1.632 | -1.037 |
| km 18 | 1.633 | -0.995 |
| km 19 | 1.647 | -0.949 |
| km 20 | 1.671 | -0.876 |

Near-field water levels for the existing conditions were extracted from the No.5 Road model for comparison with local water levels in the Tunnel removal options. The modelled water levels at the Tunnel during the 2012 freshet peak period are shown in **Figure 7-8**.

Figure 7-8 Modelled Water Level (m GD) at the Tunnel during the Period from June 22 to June 24, 2012

7.2.1.3 Flow Splits

Flow split between the Fraser River South Arm and Ladner Reach were calculated from the SOG/LFR model for conditions at maximum ebb (at 3:00) and maximum flood (at 20:00) on June 23, 2012. These are summarized in **Table 7-4**.

Table 7-4 Flow splits under existing conditions on June 23, 2012

| Condition | South Arm | Ladner Reach |
|------------|-----------|--------------|
| Ebb tide | 94% | 6% |
| Flood tide | 88% | 12% |

7.2.2 Morphodynamics

Bed evolution under existing conditions was modelled using the No.5 Road model over the freshet period for comparison with Tunnel removal options. **Figure 7-9** shows the modelled sedimentation pattern at the end of the simulation.

Figure 7-9 Modelled Local Morphodynamic Evolution under Existing Conditions Over the 2012 Freshet

Similar to the findings from the low-flow model results for the existing conditions (**Figure 7-5**), the modelled sedimentation pattern matched reasonably with the established sedimentation patterns in this part of the lower Fraser River. The key difference between the low-flow and freshet simulations is that the magnitudes of sediment scour and deposition are greater over the freshet period than over the non-freshet period.

Far-field bed evolution over the freshet period under existing conditions was investigated using the SOG/LFR model. **Figure 7-10** shows the modelled sedimentation pattern from the SOG/LFR model at the end of the simulation period. As discussed in **Section 6.6.2**, the hindcast sedimentation pattern matches reasonably well with the established sedimentation patterns in the lower Fraser River.

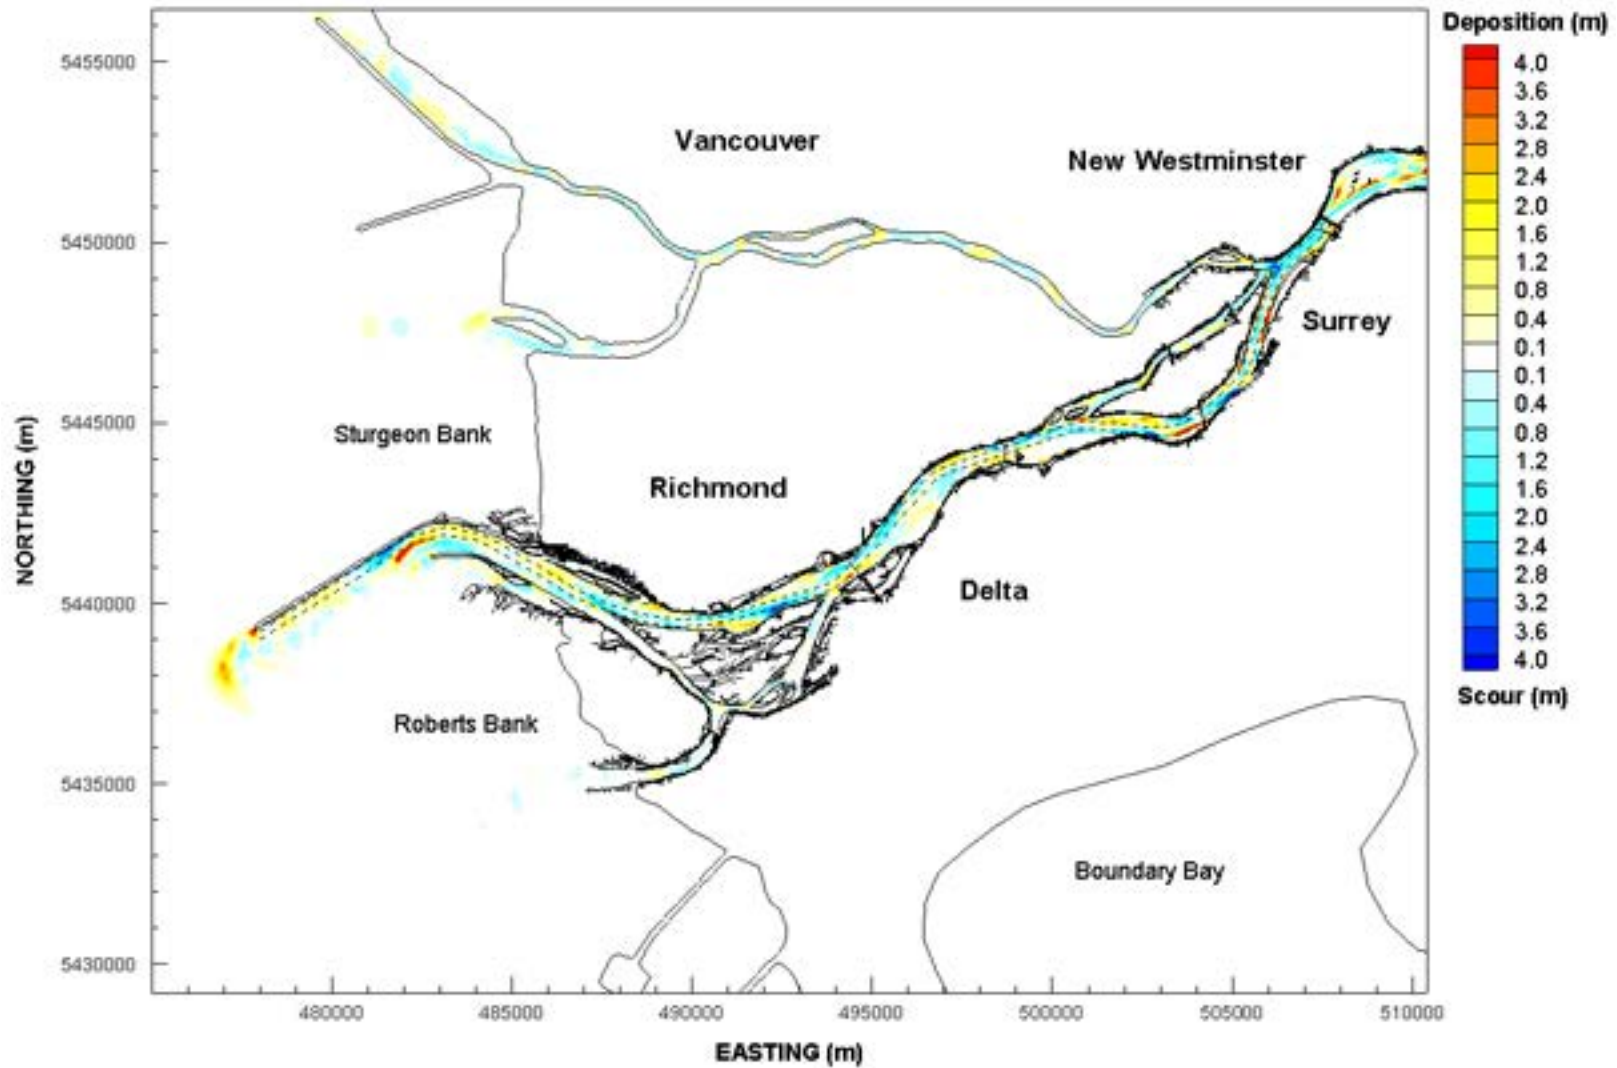

Figure 7-10 Modelled Morphodynamic Evolution under Existing Conditions During the 2012 Freshet

7.3 Trench Infilling Scenario

The trench infilling model examines the short-term channel response to Tunnel removal, assuming the trench is not backfilled. The model simulation is based on Fraser River flows and tidal water levels from the low flow period August 16 to November 14, 2012. Model results for full and partial Tunnel removal conditions are very similar, as expected based on their similar geometry (see **Section 6.3.2**). Therefore, only the full Tunnel removal condition is presented here since the results are also applicable to the partial Tunnel removal condition.

7.3.1 Hydrodynamics

7.3.1.1 Current Velocities

Current velocities near the time of maximum ebb tide on August 16 (day one of the Tunnel removal in the model) for the full Tunnel removal condition were extracted from the No.5 Road model. When the Tunnel is removed from the riverbed, flow is expected to decelerate over the deeper trench region. Immediately after the Tunnel is removed, the predicted surface velocity over the trench was about 1.2 m/s (**Figure 7-11**), approximately 0.5 m/s less than for the existing low-flow condition. The general pattern is similar to the existing condition, with maximum velocities on the right side of the channel.

Overall, near-bed velocities exhibit a smaller decrease than surface velocities. Predicted maximum velocity at -12 m GD elevation is approximately 1.6 m/s, occurring immediately upstream and downstream of the trench, near the right bank (**Figure 7-12**). In contrast with the existing low-flow condition, the maximum velocity occurs directly upstream and downstream of the trench, near the right bank. Velocities over the trench decreased markedly in comparison with the accelerating flow predicted for the existing condition, to around 1.0 m/s. Velocities downstream of the trench also decrease slightly to about 1.3 m/s.

Figure 7-11 Modelled Surface Velocity Distribution Immediately after the Tunnel is Removed, August 16, 2012.

Figure 7-12 Modelled Near-bed Velocity Distribution at -12 m GD Immediately after the Tunnel is Removed, August 16, 2012

7.3.1.2 Water Levels

Hourly water levels at several stations upstream and downstream of the Tunnel (**Figure 7-3**) were extracted from the SOG/LFR model over August 16, 2012. The maximum and minimum modelled water levels at these stations are summarized in **Table 7-5**.

Table 7-5 Modelled Non-freshet Water Level Statistics for August 16, 2012

| Station | Maximum Water Level (m GD) | | | Minimum Water Level (m GD) | | |
|---------|----------------------------|---------------------|------------|----------------------------|---------------------|------------|
| | Existing | Full Tunnel Removal | Difference | Existing | Full Tunnel Removal | Difference |
| km 16 | 1.29 | 1.30 | 0.01 | -1.60 | -1.60 | - |
| km 17 | 1.30 | 1.30 | - | -1.55 | -1.56 | -0.01 |
| km 18 | 1.30 | 1.30 | 0.00 | -1.53 | -1.54 | -0.01 |
| km 19 | 1.30 | 1.31 | 0.01 | -1.50 | -1.50 | - |
| km 20 | 1.31 | 1.31 | - | -1.48 | -1.48 | - |

The predicted changes in water level for the trench infilling simulation are within the range of model uncertainty and considered negligible. As such, Tunnel removal is not expected to produce a substantial change in water levels during the low-flow period prior to trench infilling.

7.3.1.3 Flow Splits

Flow splits between Woodward Reach and Ladner Reach were calculated for the maximum ebb (at 12:00) and maximum flood (at 18:00) conditions on August 16, and are summarized in **Table 7-6**.

Table 7-6 Modelled Flow Splits on August 16, 2012

| Condition | Existing | | Full Tunnel Removal | | % Difference | |
|------------|----------------|--------------|---------------------|--------------|----------------|--------------|
| | Woodward Reach | Ladner Reach | Woodward Reach | Ladner Reach | Woodward Reach | Ladner Reach |
| Ebb tide | 93% | 7% | 94% | 6% | +1 | -1 |
| Flood tide | 95% | 5% | 95% | 5% | - | - |

The predicted difference in flow splits for the low-flow period prior to trench infilling is within the range of natural variability and considered negligible. On this basis, the removal of the Tunnel is not expected to affect the flow split between Woodward Reach and Ladner Reach.

To evaluate potential changes in flow direction due to the Tunnel removal, the modelled depth-averaged velocities for (a) existing conditions and (b) conditions under full Tunnel removal for March 27, 2014 at 09:10 were compared against each other (**Figure 7-13 a and b**) and against ADCP measurements collected at the same date and time.

Tunnel removal reduces the velocity magnitude in the immediate vicinity of the excavation, but does not noticeably change the flow direction due to Tunnel removal. ADCP measurements also showed that near-bed flow direction at the Tunnel is similar to surface flow direction (**Figure 4-2**). The modelled flow splits and velocities, in combination with ADCP results indicate that Tunnel removal will not result in changes to flow patterns or increased flow into Ladner Reach.

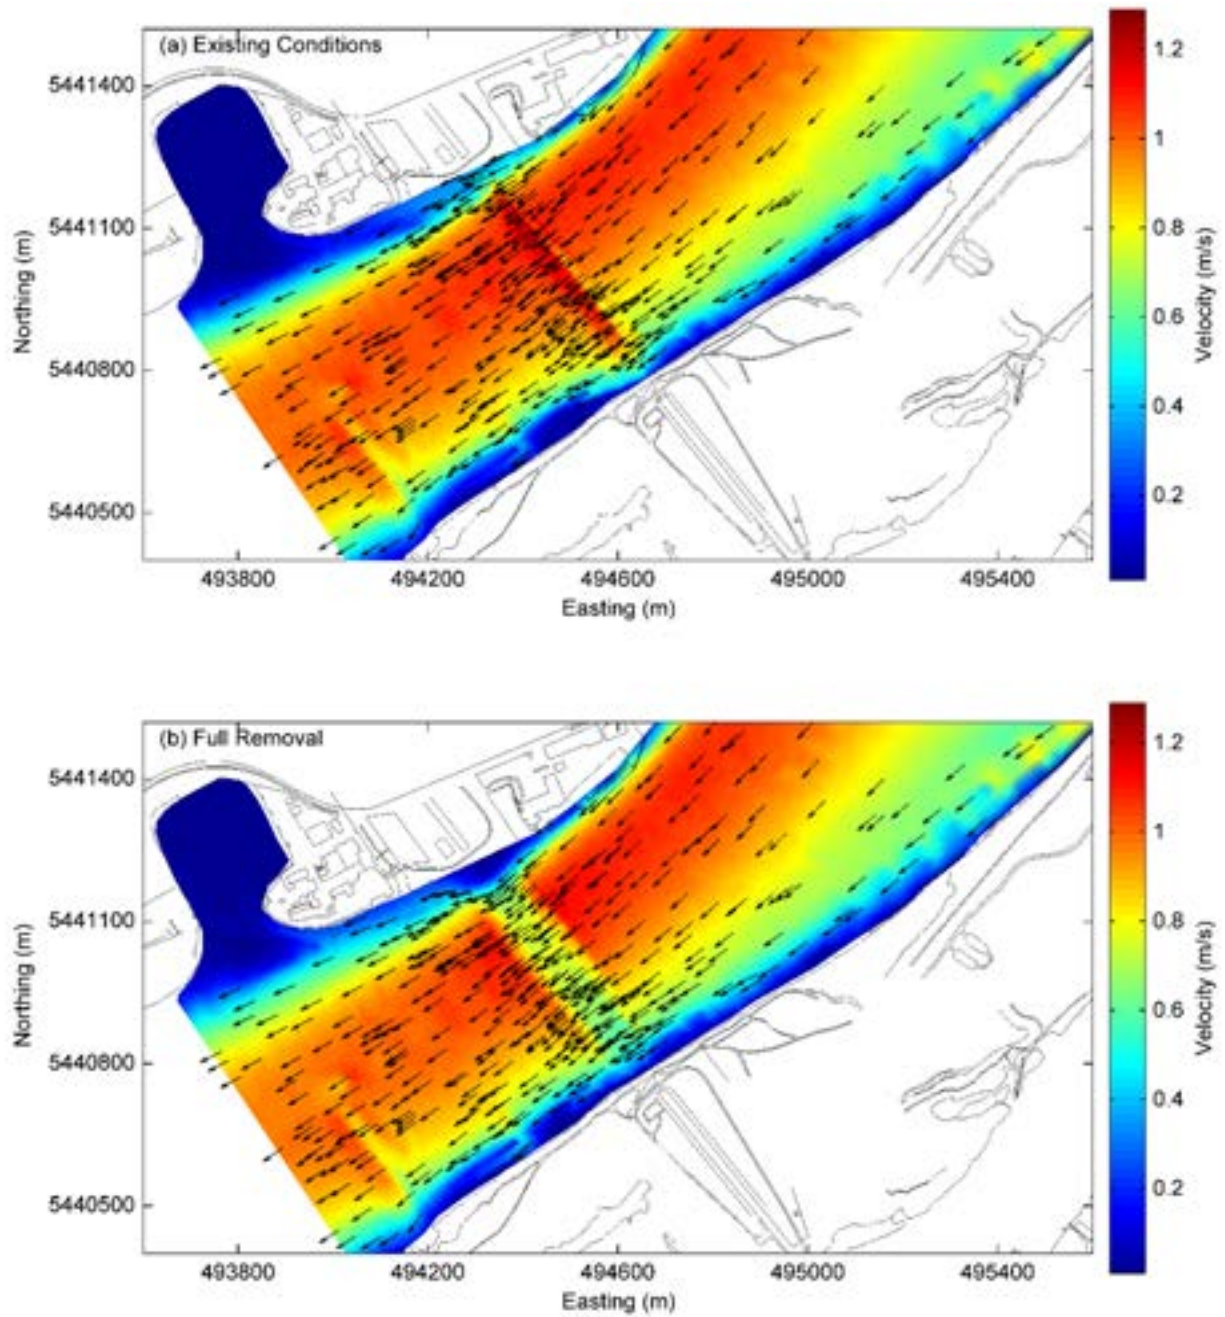

Figure 7-13 Modelled Depth-averaged Velocities under (a) Existing Conditions and (b) Conditions with Full Tunnel Removal, for March 27, 2014 at 09:10 (PST).

7.3.2 Morphodynamics

The model results show that, as the flow decelerates over the deeper trench region, sediment is deposited (**Figure 7-14** and **Figure 7-15**). Nearly complete infilling of the trench is predicted by the model over the course of the 210 day simulation. More sediment tends to deposit on the north side of the trench, where faster velocities likely carry more sediment in the water column than does the flow on the south side, before reaching the trench. At the downstream edge of the trench, the model predicts that sediment is entrained by the accelerating flow, and that the trench migrates downstream. This process is illustrated in **Figure 7-16**, which shows a time-series of the bed profile along the centreline of the navigation channel under the conditions of full Tunnel removal.

As shown on **Figure 7-16**, after 210 days of simulation, the trench has mostly filled in, but temporary bed lowering of one to two metres in the region between the Tunnel and the Lulu Island–Delta water main occurs. The magnitude of lowering is about one metre greater than the general bed lowering predicted under existing conditions over the same period. The figure also shows deposition in a localized region directly upstream of the Lulu Island–Delta water main. The bathymetric survey conducted in April 2014 showed considerable scour in this area, concentrated within approximately 25 m of the water main alignment. Previous work by NHC suggests the scour upstream of the Lulu-Delta water main may be a seasonal phenomenon, wherein upstream flow driven by large winter tides results in scour on the lee (upstream) side of the apron, and the scoured area is then filled in during freshet, when bedload is high and flow reversals do not occur (NHC 2015). If this is the case, the model would be expected to fill in the scoured region based on flow conditions and sediment load during freshet.

Figure 7-14 Bed Elevation after 210 Simulation Days Under Full Tunnel Removal Conditions with Trench Infilling

Figure 7-15 Morphodynamic Evolution after 210 Day Simulation of Trench Infilling under Full Tunnel Removal conditions⁸

Figure 7-16 Riverbed Profile along the Centreline of the Navigation Channel under Full Tunnel Removal Conditions

⁸ Flow is From Right to Left.

To visualize changes to the sedimentation pattern due to the Project, a bed difference map (Figure 7-17) was prepared showing the difference between the bathymetry under existing conditions and full Tunnel removal after 210 days' simulation. Positive values indicate that the bed elevation under the Tunnel removal condition would be shallower than the bed elevation under existing conditions at the end of the freshet. Negative values indicate that the bed elevation under the proposed condition would be deeper than the bed elevation under existing conditions. After 210 days of simulation, the trench is mostly filled in, but bed lowering of up to two metres persists north of the navigation channel, between the Tunnel and the Lulu Island–Delta water main. Lowering does not affect the water main at 210 days. This lowering is expected to be temporary. It is most likely caused by sediment being “trapped” by the trench, resulting in less sediment available to replenish the downstream bed. Given the general tendency of the trench to migrate downstream as it fills in, it is reasonable to expect one to two metres of scour to occur upstream of the water main crossing within one or two freshets after Tunnel removal.

Figure 7-17 Bed Elevation Difference between Existing Conditions and Full Tunnel Removal After 210-days' Trench Infilling Simulation⁹

⁹ Positive Values Indicate Higher Bed Elevations for Full Tunnel Removal than for Existing Conditions.

7.4 Post-Infilling Scenario

As discussed in **Section 7.3.2**, deposition of river sediments is expected to fill in the trench completely within one to two years after removal. The post-infilling model examines the potential Project-related changes to hydraulics and morphodynamics after trench infilling is complete. The simulation is based on freshet conditions, between May 26 and July 27, 2012.

7.4.1 Hydrodynamics

7.4.1.1 Current Velocities

Current velocities were extracted from the No.5 Road model at maximum ebb tide, about 13:00 on June 23, 2012. The results show that, once the Tunnel has filled in, the zone of acceleration previously seen in existing conditions (i.e., with the Tunnel), no longer occurs (**Figure 7-18** and **Figure 7-19**). Velocities in the middle of the navigation channel are more uniform, at 2.3 m/s. The flow acceleration pattern can still be seen at the Lulu Island–Delta water main crossing, downstream.

Figure 7-18 Modelled Surface Velocity Distribution under Full Tunnel Removal Conditions, Post-infilling, at Summer Ebb Tide

Figure 7-19 Modelled Near-bed Velocity Distribution at -12 m GD Elevation under Full Tunnel Removal Conditions, Post-infilling, at Summer Ebb Tide

To better visualize the difference between existing conditions (**Figure 7-6**) and the full Tunnel removal conditions (**Figure 7-18**), velocity difference maps were prepared for full Tunnel removal conditions minus existing conditions at the surface (**Figure 7-20**), and near the bed at -12 m GD elevation (**Figure 7-21**).

Figure 7-20 and **Figure 7-21** show the following post-infilling changes relative to existing conditions:

- Tunnel removal (both full and partial) is predicted to reduce surface velocities by about 0.3 m/s to 0.5 m/s between the Tunnel and about 50 m downstream. The reduction in near-bed velocities at -12 m GD elevation is smaller, ranging from 0.1 m/s to 0.4 m/s.

- Full removal of the Tunnel may require removal of existing bank protection materials along the Fraser River right (north) bank. This is expected to yield reductions in surface velocities by about 0.2 m/s along this bank, extending about 400 m downstream of the Tunnel.
- Full Tunnel removal may require removal of existing bank protection materials along the left (south) bank, which is predicted to result in reductions in surface velocities by about 0.5 m/s. The region that will experience this reduction extends from the Tunnel to about 150 m downstream.

Figure 7-20 Modelled Difference in Surface Velocities between Full Tunnel Removal Conditions and Existing Conditions (i.e., with the Tunnel) During Summer Ebb Tide

Figure 7-21 Modelled Difference in Near-bed Velocities at -12 m GD Elevation between Full Tunnel Removal Conditions and Existing Conditions (i.e., with the Tunnel) During Summer Ebb Tide

7.4.1.2 Water Levels

Hourly water levels at several stations upstream and downstream of the Tunnel (**Figure 7-3**) were extracted from the SOG/LFR model for the period from June 22 to June 24, 2012. The maximum and minimum modelled water levels at these stations during this period under existing conditions and the full Tunnel removal conditions are summarized in **Table 7-7**. As discussed in **Section 7.3**, model results for full and partial Tunnel removal conditions are virtually identical, as expected based on their similar geometry (**Section 6.3.2**). Therefore, only the full Tunnel removal condition is presented here since the results are also applicable to the partial Tunnel removal condition.

Table 7-7 Modelled Freshet Water Level Statistics and Differences between Existing Conditions and the Full Tunnel Removal Conditions for June 22 to June 24, 2012

| Station | Maximum Water Level (m GD) | | | Minimum Water Level (m GD) | | |
|---------|----------------------------|----------|------------|----------------------------|----------|------------|
| | Existing | Proposed | Difference | Existing | Proposed | Difference |
| km 16 | 1.61 | 1.61 | - | -1.14 | -1.14 | - |
| km 17 | 1.63 | 1.63 | - | -1.04 | -1.04 | - |
| km 18 | 1.63 | 1.63 | - | -0.10 | -0.10 | - |
| km 19 | 1.65 | 1.65 | - | -0.95 | -0.96 | -0.01 |
| km 20 | 1.67 | 1.67 | - | -0.88 | -0.88 | - |

The predicted change in water level for the post-infilling simulation is within the natural variability of the river system and considered negligible. On this basis, the proposed Tunnel modifications are not expected to affect water levels in the adjacent channel reach during the freshet.

7.4.1.3 Flow Splits

As discussed in **Section 4.1.2**, alteration of flow patterns at the nose of Kirkland Island where Ladner Reach splits off was identified as a concern during early Project planning, as it could potentially result in scour and erosion in Ladner Reach. Conversely, there were concerns about Tunnel removal altering flow patterns.

Flow split between Woodward Reach and Ladner Reach was calculated for the maximum ebb (at 13:00) and maximum flood (at 20:00) conditions for June 23, 2012, and compared with that from the existing conditions (**Table 7-8**). The predicted changes in flow splits are within the range of natural variability and considered negligible. On this basis, Tunnel removal is not expected to alter the flow split between Woodward Reach and Ladner Reach.

Table 7-8 Flow splits under existing conditions on June 23, 2012

| | Existing | | Full Tunnel Removal | | % Difference | |
|------------|----------------|--------------|---------------------|--------------|----------------|--------------|
| | Woodward Reach | Ladner Reach | Woodward Reach | Ladner Reach | Woodward Reach | Ladner Reach |
| Ebb Tide | 94% | 6% | 94% | 6% | - | - |
| Flood Tide | 88% | 12% | 89% | 11% | -1 | +1 |

7.4.2 Morphodynamics

7.4.2.1 Near-field Changes

Near-field bed evolution for the full Tunnel removal option was modelled using the No.5 Road model over the freshet period. Similar to the existing conditions simulation, the model predicted bed lowering within 150 m upstream and downstream of the Tunnel. However as shown in **Figure 7-22**, compared with existing conditions there will be about 0.5 – 1.0 m less erosion. This is consistent with the results of the hydraulic analysis which show that the flow will not accelerate across the Tunnel cross-section and that current velocities will be generally lower when the Tunnel is removed. The consequent reduction in erosion in this region will likely result in less sediment available to be deposited in the channel downstream between the Tunnel and Lulu Island–Delta water main, contributing to bed lowering of up to 1.0 m in that segment.

Figure 7-22 Local Morphodynamic Evolution under Full Tunnel Removal Conditions during the Freshet

7.4.2.2 Far-Field Changes

Far-field sedimentation changes under Tunnel removal conditions were investigated using the SOG/LFR model. To visualize the far-field changes to the sedimentation pattern from the Tunnel removal, modelled differences in bed elevations were mapped. **Figure 7-23** shows the difference in bed elevations for existing conditions and Tunnel removal conditions at the end of the freshet simulation period.

Simulated changes in bed elevation as a result of Tunnel removal following the freshet period are limited to the region within about 500 m upstream and 1500 m downstream of the Tunnel. The model suggests that deposition of about 0.5 m will occur in the middle part of the channel upstream of the Tunnel, and north of the navigational channel downstream. Bed lowering of 0.5 to 1.0 m is expected to occur at the margins of the channel, and in the navigational channel downstream of the tunnel. Negligible changes (i.e., $< \pm 0.05$ m) are predicted to occur to the bed levels adjacent to Tilbury Island.

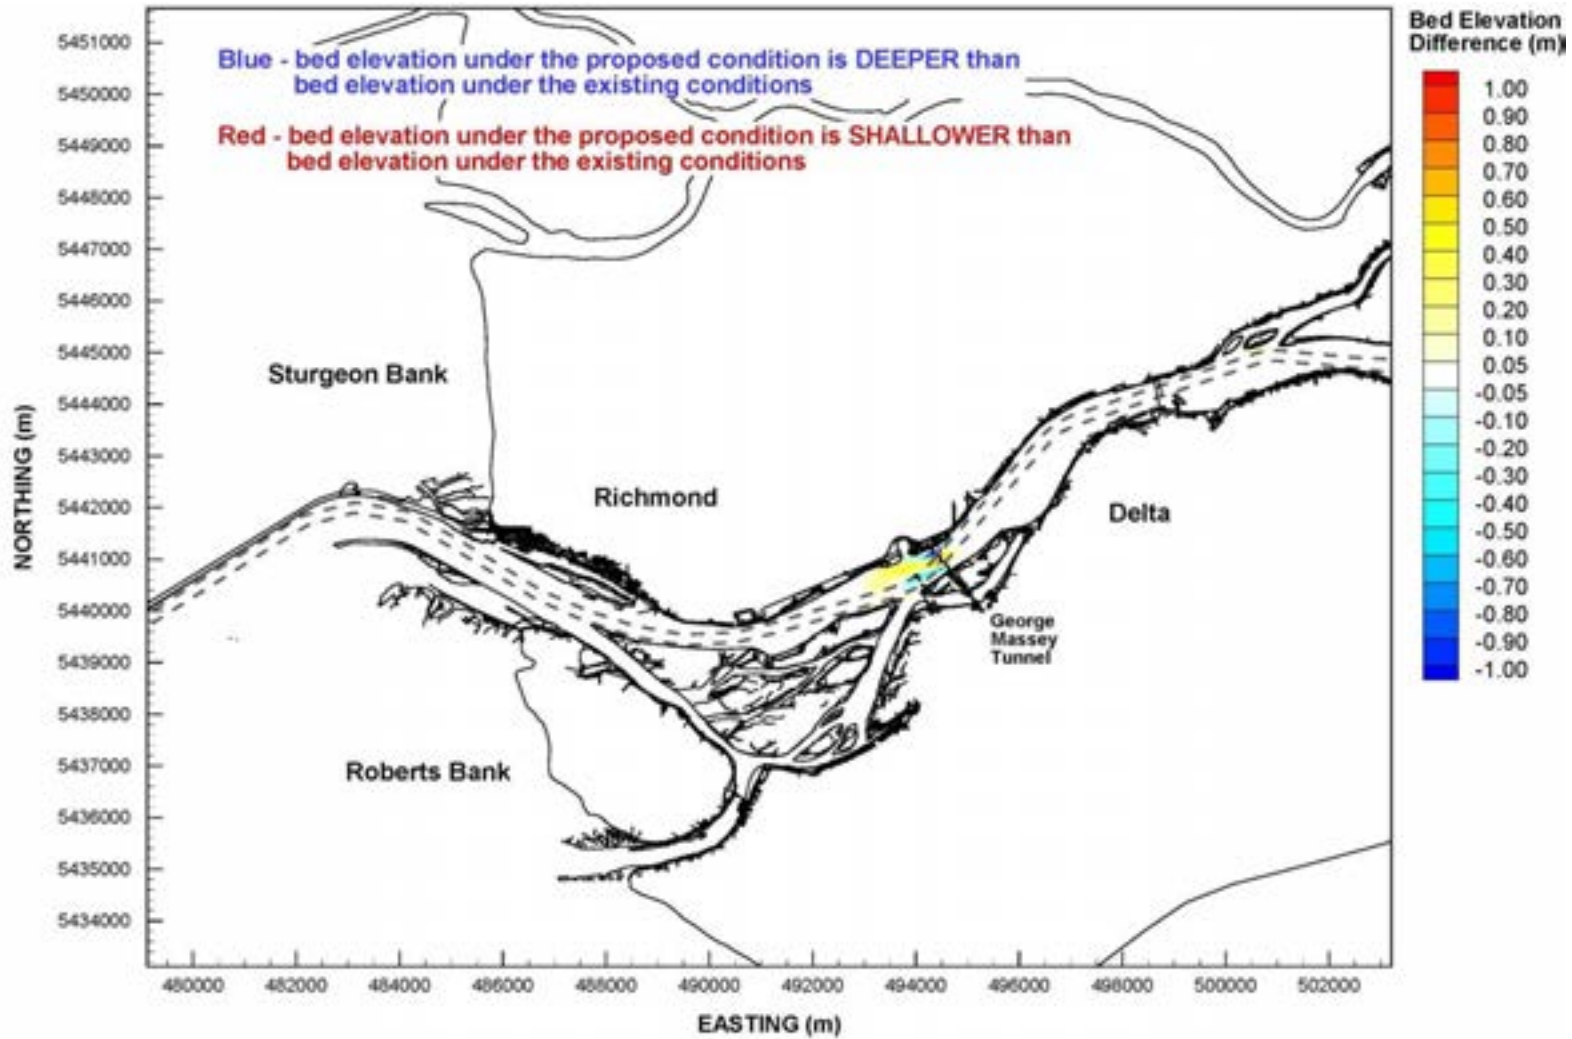

Figure 7-23 Modelled difference in Far-field Bed Elevations between the Full Tunnel Removal Conditions and Existing Conditions from Tilbury Island to the – SOG/LFR Model

The SOG/LFR model was used to predict changes to the dredging volumes required to maintain the existing navigational draft through the lower Fraser River. Modelled dredging volumes under existing and Tunnel removal conditions are summarized in **Table 7-9**. The net change in dredging requirement predicted by the model represents less than 0.5% of the existing total dredge requirement, and falls within the range of model uncertainty for sediment transport. No change in overall dredging requirement is expected to result from the Project.

Table 7-9 Required Maintenance Dredging Volumes (m³) under Existing Conditions and Proposed Tunnel Removal Conditions

| Reach | km | Existing (m ³) | Tunnel Removal (m ³) | Difference (m ³) |
|--------------------|----------|----------------------------|----------------------------------|------------------------------|
| Sand Heads | -1 to 1 | 33,000 | 33,000 | 0 |
| Sand Heads Reach | 1 to 4 | 416,200 | 416,000 | -200 |
| Steveston Bend | 5 to 7 | 342,900 | 342,800 | -100 |
| Steveston Cut | 7 to 10 | 460,100 | 459,900 | -200 |
| No. 5 Road | 16 to 18 | 39,000 | 39,400 | 400 |
| Gravesend Reach | 20 to 22 | 73,600 | 73,500 | -100 |
| Purfleet Reach | 24 to 27 | 168,800 | 168,500 | -300 |
| St. Mungo's Bend | 27 to 29 | 332,300 | 331,900 | -400 |
| Annieville Channel | 32 to 34 | 620,400 | 620,600 | 200 |
| Total | - | 2,486,300 | 2,485,600 | -700 |

8.0 Discussion of Potential Changes Due to the Project

This section summarizes potential changes to river hydraulics and morphology as a result of the Project. The assessment is based on a synthesis of the field observations, and hydrodynamic and morphodynamic model results.

8.1 Construction Phase

8.1.1 New Bridge Crossing

The new bridge will be a clear-span crossing. Potential change to river hydraulics and morphology due to bridge construction activities are limited to the upgrading of existing riprap bank protection on the left and right banks. If banks are left intact during Tunnel removal (i.e., the partial removal option), bank protection upgrades would be limited to placement of additional riprap.

Assuming upgrades are limited to moderate rock placement on the existing armoured slope (i.e., no instream excavation, no increase in rock footprint and no river training works), this work would not result in changes to river hydraulics or morphology. This type of riprap placement would generate a limited supply of suspended sediment, assuming standard best management practices are adhered to, such as use of washed rock with no fines or debris. Changes to the river system due to suspended sediment input resulting from such work would be negligible.

8.1.2 Tunnel Removal

Tunnel removal has the potential to result in changes to river hydraulics and fluvial morphology during the Project construction phase. The nature and severity of these changes depends heavily on Tunnel removal methodology and timing. Tunnel removal is expected to involve removing the rock apron/ballast and concrete mattress, excavating beneath the Tunnel segments to break suction, and then floating the pre-cast concrete Tunnel segments to the surface. The process is expected to take several months to complete. The potential changes are discussed below.

8.1.2.1 Local Scour and Deposition

Local scour and deposition are expected during Tunnel removal due to flow acceleration around exposed edges of Tunnel segments. Since the segments are expected to be removed in sequence, flow will accelerate around the exposed ends and entrain sediment, which would then be deposited downstream. The degree of sediment transport associated with local flow accelerations during construction will depend on time of year and associated current velocities. These changes are expected to be temporary and small in scale compared with overall bed material transport.

8.1.2.2 Suspended Sediment

Removal of the components as described above, and excavation of the river bed, will generate suspended sediment. The resulting changes to river hydraulics and morphology will depend on the ambient suspended sediment concentrations at the time of removal, river discharge, tidal amplitude, and details of Tunnel removal methods. This study has assumed Tunnel removal will commence in mid-August, after freshet flows have receded, and continue into the winter low flow period (December). Suspended sediment concentrations in the low-flow period are typically low, so change in concentrations due to Project-related input of sediment to the water column could be substantial.

The volume of suspended sediment that could be generated by the Tunnel removal was estimated and compared it to the typical ambient volumes of suspended sediment transported during the Tunnel removal period. Each Tunnel segment is overlain by approximately 28,000 m³ of sediment or sand fill material (**Figure 3-2**). Assuming this material has the same size gradation as the bed material in the lower Fraser River, approximately 10% (2,800 m³) of the overlying material would be smaller than 0.177 mm in diameter, and could therefore remain suspended in the water column (NHC 2002*b*). Assuming that removal of one tunnel segment takes two weeks, the natural or ambient volume of suspended sediment transported through the assessment area during removal of one segment ranges from a maximum of 3x10⁵ m³ in August to a minimum of 3x10⁴ m³ in December. These estimates are based on analyses of seasonal flows and measured suspended sediment concentrations in the lower Fraser River (Milliman 1980, Kostaschuk, Luternauer, et al. 1989, Attard and Venditti 2014). Based on the above estimates, the increase in suspended sediment volume due to the Tunnel removal ranges from one per cent to nine per cent over ambient volumes. Considering the natural variability of suspended sediment seasonally and annually, such an increase is considered low.

Suspended sediment concentrations resulting from Tunnel removal have not been estimated in this study. Although such an estimate could be accomplished by calculating advection and dispersion of fine sediments, it is complicated by temporal variability and tidal flow reversal at the site. Numerical dispersion models are capable of estimating sediment concentrations under these conditions.

Depositional changes resulting from suspended sediment generation are expected to be minimal. Suspended fine sediments generated during Tunnel removal would be transported to the Strait of Georgia before deposition could occur. Since the incremental volume of suspended sediment generated during Tunnel removal is expected to be small in comparison with the ambient load, and the depositional area at Sand Heads is large, no noticeable changes to deposition in the Strait of Georgia are expected.

8.2 Operation Phase

8.2.1 New Bridge Crossing

No changes to river hydraulics and morphology are expected to result from the new bridge during the Project operation phase. Normally, hardening of banks with riprap could result in incremental changes to both hydraulics and morphology, but the banks are already hardened and simply upgrading the existing protection would not increase these changes.

8.2.2 Tunnel Removal

8.2.2.1 Current Velocities

Compared with existing conditions, minor changes in current velocities are expected to result from Tunnel removal. The predicted changes in velocity do not suggest that Tunnel removal would result in substantial bank erosion, barriers to fish migration, or impediments to vessel traffic. Changes are as follows:

- Local reductions of about 0.3 m/s in surface velocities at the crossing alignment during summer ebb tide conditions
- Decrease in surface velocity of about 0.2 m/s at the right bank for 400 m downstream of the crossing during summer ebb tide conditions
- Decrease in surface velocity of about 0.5 m/s at the left bank for about 150 m downstream of the crossing due to slight differences in bank geometry
- Slight decrease in near-bed velocity in the navigation channel, of around 0.1 to 0.4 m/s at the crossing alignment
- Changes to velocity during summer flood tide are similar, but smaller in magnitude and extents
- Changes to velocity during winter ebb tide are similar but smaller in magnitude
- Winter flood tide changes in velocity are comparable to the ebb tide condition, but smaller in magnitude. As with the summer flood tide condition, no changes in velocity are anticipated along the banks at the surface.

8.2.2.2 Water Levels

Predicted changes in water level resulting from Tunnel removal varied between an increase of two millimetres and a decrease of five millimetres. These changes are within the range of natural variability and considered negligible. Tunnel removal is not expected to produce a change in water levels.

8.2.2.3 Flow Splits

The predicted changes in flow splits are within the range of natural variability and considered negligible. Tunnel removal is not expected to cause changes to the flow split between Woodward Reach and Ladner Reach. This suggests that Tunnel removal is not likely to result in the development of Ladner Reach through erosion of Deas Island and/or the nose of Kirkland Island.

8.2.2.4 Salt Wedge

Salinity is not incorporated in the model analyses. However, because the Tunnel elevation is several metres lower than the bed downstream (km 15) and upstream (km 19), temporary lowering of bed levels by one to two metres at the Tunnel is not likely to influence the overall distance of salt wedge intrusion. Results of hydrodynamic modelling, as discussed in **Section 16.7** of the Application, indicates that the proposed removal of the Tunnel will not affect the behaviour of the salt wedge.

8.2.2.5 Trench Infilling and Migration

The primary concern during the Project operation phase is that the knickpoint in the longitudinal profile of the river created by the trench feature could propagate either upstream or downstream, or both, leading to bed degradation and bank erosion. Modelling suggests the trench is mostly filled in after 210 days following Tunnel removal; however, bed lowering of up to two metres persists north of the navigation channel between the Tunnel and the Lulu Island–Delta water main. Lowering does not appear to affect the water main pipe at 210 days; however, given the general tendency of the trench to migrate downstream as it fills in, it is reasonable to expect one to two metres of scour to occur at the upstream margins of the water main scour protection within one or two freshets after Tunnel removal.

The expected changes beyond the trench footprint are in the same order as normal variation in bed levels in the lower Fraser River. Historical bathymetric surveys indicate that the riverbed at the Tunnel crossing is very dynamic, with bed lowering of 0.15 to 0.50 m/year attributed to changes in flow alignment and/or reduction in sediment supply, depending on the time period considered. Temporary scour during freshets can be on the order of several metres, especially when the migration of sand dunes as much as four metres in height is taken into account.

8.2.2.6 Post-Infilling Morphological Changes

Near-field modelling (No.5 Road model) suggests the magnitude of bed lowering will be 0.5 to 1.0 m less with Tunnel removal than under existing conditions. This will likely result in less sediment available to be deposited in the channel downstream between the Tunnel and the Lulu Island–Delta water main, and consequently bed lowering of about 0.5 m in the northern part of the navigational channel, from about 150 m downstream of the Tunnel to upstream of Lulu-Delta watermain.

Far-field modelling (SOG/LFR model) suggests changes are limited to about 500 m upstream and 1500 m downstream. Deposition of about 0.5 m is expected in the middle of the channel upstream of the Tunnel, and north of the navigational channel downstream of the Tunnel. Bed lowering of 0.5 to 1.0 m is expected to occur at the margins of the channel, and in the navigational channel downstream of the tunnel. Negligible changes ($< \pm 0.05$ m) are predicted to occur to the bed levels adjacent to Tilbury Island.

ROCK PROTECTION (1500'±) ON TUNNEL ELEMENTS

14-E-1610

SEQUENCE OF OPERATIONS

- I Immediately after completion of sand jetting fill 5' minus gravel to lines and grades shown.
- II Follow 5' minus with 3 ft. layer of 500 lb rock.
- III Follow 500 lb rock with 1/2" articulated concrete mats.
- IV Place 1500 lb rock each side of Element.
- V Cover mats with 3'-6" layer of 500 lb rock.
- VI Adjust slopes to required grade with 1500 lb rock.

NOTE: Loading tops of elements with 1500 lb rock can follow between above operations.

1.0 Purpose

This attachment provides a detailed description of the development, calibration, and validation of the numerical model used to investigate potential Project construction- and operation-related changes to the lower Fraser River hydraulic conditions (water levels, velocities, flow patterns) and morphology (sediment transport and riverbed profile). The model results that show the potential changes are provided in the main body of this report.

2.0 Numerical Models: TELEMAC-MASCARET System

The potential changes to river hydraulic conditions and morphology were investigated using the TELEMAC-MASCARET modelling system (TELEMAC system), which is described in the main body of the technical data report. The TELEMAC system is recognized throughout the world, with users that include HR Wallingford, BC Hydro, Hydro-Quebec, and the Canadian Coast Guard, which uses TELEMAC-2D to predict current speeds and patterns in the lower Fraser River, and to forecast available water depths for vessels navigating the Fraser River South Arm (see <http://www2.pac.dfo-mpo.gc.ca/>). The model output is published online on a weekly basis and available to river pilots, Port of Vancouver, and shipping companies to assist them in determining maximum draft and the best sailing times. All TELEMAC system modules were developed in accordance with the quality assurance procedures followed in Électricité de France's Studies and Research Division.

The various TELEMAC system modules use high-capacity algorithms based on the finite element method. TELEMAC discretizes space in the form of an unstructured grid of triangular elements, which means that the grid can be refined in areas of special interest. This approach avoids the need for systematic use of embedded models, as is the case with the finite-difference method.

For this study, two TELEMAC system modules were applied, with the TELEMAC-3D module used to compute the physical processes of tidal and river currents, while the SISYPHE module was used to compute sediment transport. These modules are described below.

2.1 TELEMAC-3D Hydrodynamic Model

TELEMAC-3D is a three-dimensional model that solves the Reynolds-Averaged Navier-Stokes equations in unstructured meshes obtained by superimposition of two-dimensional meshes of triangles. Its main outputs, obtained at each point in the resolution mesh in three dimensions, are velocity in all three directions, and the concentrations of transported quantities. TELEMAC-3D's prominent applications can be found in free surface flow, in both seas and rivers, and can take several processes into account, including the following that pertain to the Project study:

- Influence of temperature and/or salinity on density
- Bottom friction
- Influence of the Coriolis force

- Influence of air pressure and wind
- Consideration of the thermal exchanges with the atmosphere
- Sources and sinks for fluid moment within the flow domain
- Dry areas in the computational domain, in this case, tidal flats
- Current drift and diffusion of a tracer, with generation or disappearance terms

When drying occurs, the water depth falls to zero and the planes collapse to a zero inter-layer spacing. Finite-volume style numerical techniques are used to ensure that both water and a tracer can be well-conserved in the presence of drying and subsequent re-wetting.

2.2 SISYPHE Sediment Transport Model

SISYPHE is the sediment transport and bed evolution module of the TELEMAC system. SISYPHE can be used to model complex morphodynamic processes in diverse environments, such as coastal systems, rivers, lakes, and estuaries, for different flow rates, sediment size classes, and sediment transport modes. In SISYPHE, sediment transport processes are grouped as bed load, suspended load or total load, with an extensive library of bed load transport relations. SISYPHE is applicable to non-cohesive sediments that can be uniform (single-sized) or non-uniform (multiple-sizes), cohesive sediments (multi-layer consolidation models), as well as sand-mud mixtures.

A number of physically-based processes are incorporated into SISYPHE, such as the influence of secondary currents to precisely capture the complex flow field induced by channel curvature, the effect of bed slope associated with the influence of gravity, bed roughness predictors, and areas of non-erodible bed, among others. SISYPHE can be coupled to the depth-averaged shallow water module, TELEMAC-2D, or to TELEMAC-3D.

2.3 Model Framework

For this study, TELEMAC-3D and SISYPHE were internally coupled to simulate tidal and river currents, and local bed scour and deposition. The current field is first simulated by TELEMAC-3D, which then transfers the current velocity values and water depths to SISYPHE to compute scour and deposition of the riverbed. The new bed elevation computed by SISYPHE is fed back into TELEMAC-3D to re-compute the flow hydrodynamics. The model coupling flow diagram is shown in **Figure 1**.

Figure 1 TELEMAC Model Coupling Flow Diagram

The time step of the SISYPHE sediment transport model was the same as the time step of the TELEMAC-3D model. This allows the hydrodynamic variables to be transferred to SISYPHE at each time step, which in turn, sends the updated bed elevation back to the hydrodynamic model for the next time step.

2.4 Model Descriptions

Two TELEMAC models were developed for the study: (1) the Strait of Georgia/Lower Fraser River (SOG/LFR) model, and (2) the No.5 Road model¹. The SOG/LFR model mesh extends from Ballenas Island at its north boundary to Port Renfrew at its west boundary (**Figure 2**). The model also includes Fraser River up to km 42, downstream of Port Mann Bridge. The No.5 Road model mesh extends from 1,300 m upstream of the Tunnel to 700 m downstream of the Tunnel (**Figure 3**).

¹ The local region model is referred to as the No.5 Road model in reference to the name commonly used for the reach of Fraser River at the Tunnel.

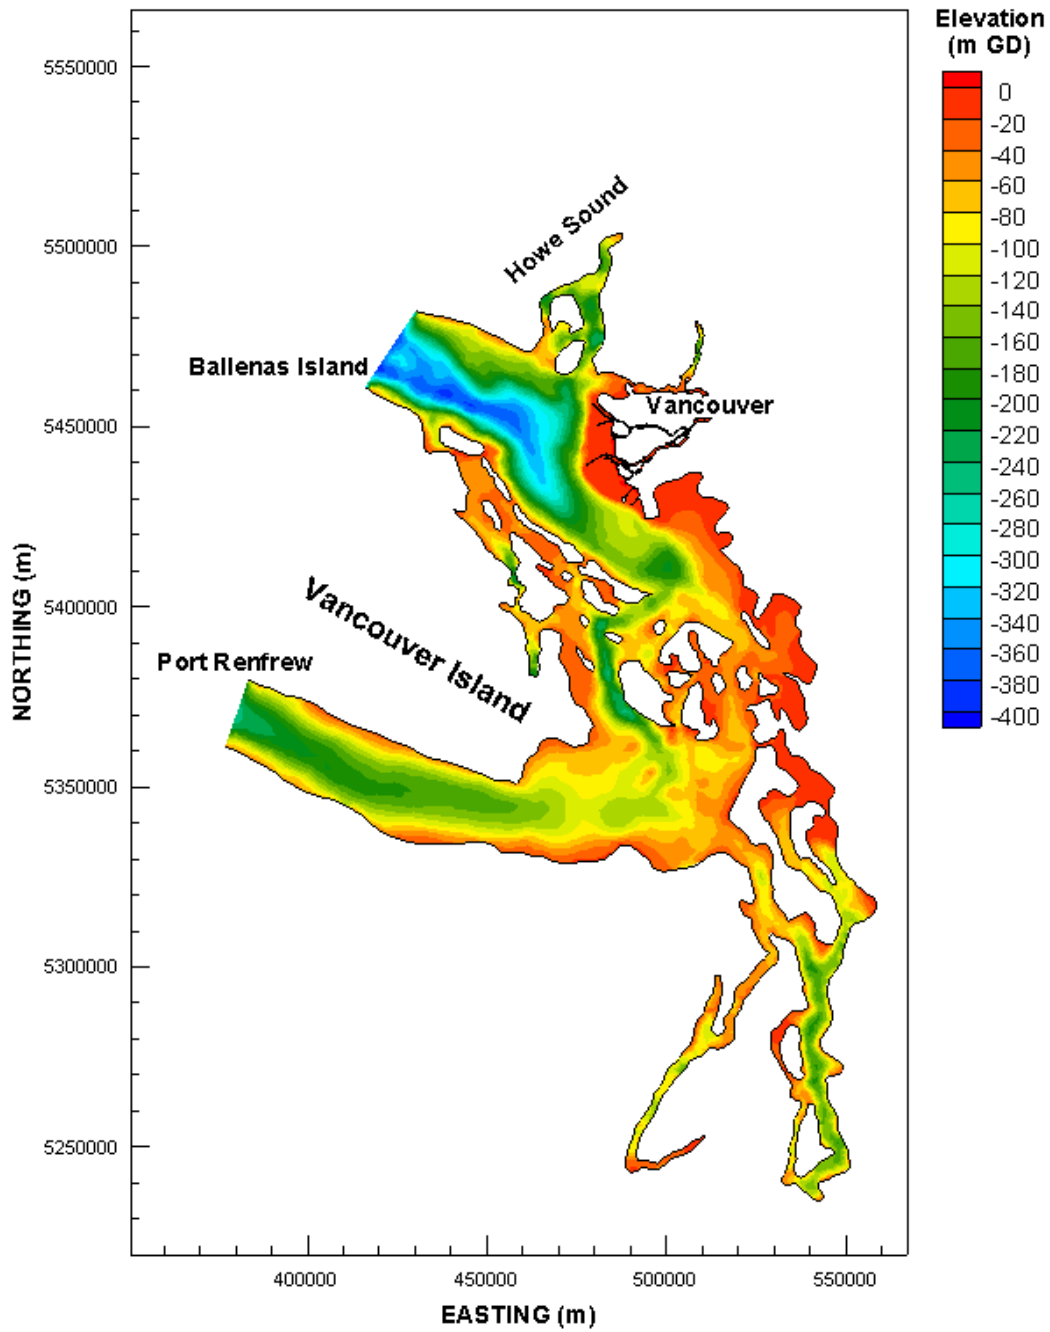

Figure 2 TELEMAC Strait of Georgia / Lower Fraser River Model Mesh Extent

Figure 3 TELEMAC No.5 Road Model Mesh Extent

The SOG/LFR Model was used to evaluate far-field hydraulic impact and sedimentation associated with the proposed options. The model mesh has approximately 35,000 nodes, 63,000 elements and 10 levels in the vertical. The element lengths vary from approximately 3,000 m in the Strait of Georgia to about 50 m in the lower Fraser River. In the river reach near the Tunnel, the element lengths were further refined to about 30 m. The SOG/LFR model is driven at its open boundaries (Ballenas Island and Port Renfrew) by tidal levels obtained using WebTide Tidal Prediction model (Fisheries and Oceans) based on Foreman et al. (2000). Inflows to the Fraser River at Port Mann Bridge (km 42) were computed using a hydraulic model of the Fraser River that uses the MIKE11 one-dimensional hydrodynamic software developed by the Danish Hydraulic Institute. NHC prepared the Fraser River MIKE11 model for Fraser Basin Council in 2006 (NHC and Triton 2006) and updated it for B.C. Ministry of Environment two years later (NHC 2008).

The No.5 Road model was used to evaluate near-field hydraulic and sedimentation associated with the proposed options. The model mesh has approximately 11,000 nodes, 21,000 elements, and 10 levels in the vertical. The element lengths vary from approximately 20 m in the upstream to about 5 m in the vicinity of the Tunnel. This spatial resolution was used to better define the Tunnel geometry and hence better identify features in the flow field which could impact the local deposition pattern. The No.5 Road model is driven at its upstream boundary by a discharge and at its downstream boundary by a water level, both specified from the aforementioned Fraser River MIKE11 model.

2.4.1 Bathymetry

The model bathymetry was derived using the following datasets:

- Bathymetric survey data collected by CRA Canada Survey Ltd. on April 2, 2014. That survey extended approximately 500 m upstream and downstream of the Tunnel (**Figure 4**).
- For the Fraser River, 2014 bathymetric survey data from Public Works and Government Services Canada, and 2005 Fraser Basin Council LiDAR data were used.
- For Puget Sound, the Strait of Georgia, and Juan de Fuca Strait, the coarse dataset from the Canadian Hydrographic Service (CHS) bathymetry data was used.

Figure 4 CRA Canada Surveys Ltd. April 2, 2014 Bathymetry Survey Result

2.4.2 Sediment Transport

The van Rijn formula (1993) was used to compute bed load and suspended transport. The formula distinguishes between sediment transport below the reference height, which is treated as bedload transport, and sediment transport above the reference height, which is treated as suspended load. Sediment is entrained in the water column by imposing a reference concentration at the reference height. The reference height is a function of effective roughness height, dune/ripple height and water depth.

The model incorporates transport of suspended bed materials as well as bed load. Sediment sizes in the model were based on known characteristics of Fraser River bed materials. Model sediment had a D_{50} (median diameter) of 250 μm and D_{90} (ninetieth percentile diameter) of 450 μm , based on surface samples collected by McLaren and Ren (1995) in the lower Fraser River between February 9 and April 7, 1993.

2.5 Model Limitation

Salinity was not incorporated in the model analyses; thus, the potential effect of the salt wedge on sediment dynamics is not represented. However, this is not expected to have a substantial effect on the model morphodynamics because approximately 80 percent of sediment discharge in the Fraser River occurs during freshet (Milliman 1980), when the salt wedge is forced to the mouth of the river. This relationship between discharge and sediment load can be better visualized in **Figure 5**.

Figure 5 Mean Daily Discharge and Daily Suspended Sediment Load for the Fraser River at Mission during 1985 (data from Water Survey of Canada 1985)

Studies by Ward (1976) and Villard and Church (2003) stated that the salt wedge rarely extends farther than Steveston Bend when the Fraser River flow is greater than 5,000 m³/s. **Figure 6** shows the 2012 Fraser River flow at Hope and specific conductivity (function of salinity) measured from Environment Canada Fraser River Water located about three kilometres upstream of the Tunnel. The figure shows that limited saline water was detected at the buoy when the flows were greater than 4,500 m³/s.

Figure 6 2012 Fraser River flow and Environment Canada Quality Monitoring Station

It is anticipated that the model could underestimate sediment shoaling in the lower reaches between Sand Heads and Steveston Bend, where the salt wedge persists during the freshet. Since the Tunnel is approximately 10 km upstream of the Steveston Bend, this simplification should not have a large influence on the modelling results during the freshet period.

During the non-freshet period, when the salt wedge could intrude over 30 km upstream of Sand Heads, the sediment load in the Fraser River is small compared to that during the freshet and the sediment movement is also small. Thus, not incorporating salinity into the model analyses should not have a large influence on the modelling results during the non-freshet period.

3.0 Model Calibration and Validation

A numerical hydrodynamic and sediment transport model requires adequate field data to perform calibration and verification of the model. For this study, both the hydrodynamic and the morphodynamic components of the model were validated using observed datasets collected from the study area and additional experimental data published in peer-reviewed literature.

To verify that both the SOG/LFR and No.5 Road models were subjected to the same hydraulic conditions, the modelled flow and water levels from the two models at km 18 and km 19 (near the Tunnel) of the Fraser River were compared and found to have good agreement (**Figure 7**). The root-mean-square error (RMSE) of the SOG model compared to the observed water levels at Deas Island was 0.23 m. The RMSE of the No.5 Road model compared to observed water levels was 0.22 m. The RMS deviation between the SOG and No.5 Road modelled water levels was 0.14 m.

Figure 7 Comparison of Observed and Modelled Water Levels at Deas Island for the SOG/LFR and No.5 Road Models, during Peak of 2012 Freshet

3.1 Strait of Georgia/Lower Fraser River Model

The SOG/LFR model results were compared to the following observed datasets:

- Water levels at Steveston, the Tunnel, Port Mann Pumping Station, New Westminster, and Point Atkinson
- Discharge, flow split, and velocities from March 7 and March 27, 2014 Acoustic Doppler Current Profiler (ADCP) measurements
- Port of Vancouver dredging records from 2006 to 2012

3.1.1 Water Levels

Water Survey of Canada (WSC) operates three water level gauges along the Fraser River downstream of the Port Mann Bridge: at Steveston, the Tunnel, and Port Mann Pumping Station. In addition, Canadian Hydrographic Service (CHS) operates a tide gauge at New Westminster along the Fraser River. Beyond the mouth of the Fraser River, the closest CHS tide gauge is located at Point Atkinson.

The three WSC hydrometric stations and the two CHS tide gauges listed above were used to calibrate the SOG/LFR hydrodynamic model. **Figure 8** shows the location of the five stations used for the model calibration and **Table 1** lists the corresponding station information. The gauge locations extend from the upstream model boundary at Port Mann Pumping Station to Point Atkinson, beyond the influence of the Fraser River discharge.

Table 1 Water Level Gauges Used for Model Calibration

| Station | Latitude | Longitude | Station ID | Type |
|---------------------------|---------------|----------------|------------|------|
| Point Atkinson | 49° 20' 15" N | 123° 15' 14" W | 7795 | CHS |
| Steveston | 49° 07' 27" N | 123° 11' 06" W | 08MH028 | WSC |
| Tunnel | 49° 07' 30" N | 123° 04' 25" W | 08MH053 | WSC |
| New Westminster | 49° 12' 00" N | 122° 54' 37" W | 7654 | CHS |
| Port Mann Pumping Station | 49° 13' 04" N | 122° 49' 37" W | 08MH126 | WSC |

CHS – Canadian Hydrographic Service

WSC – Water Survey of Canada

Figure 8 Location of Water Level Gauges Used for Model Calibration

Observed and computed hourly water levels were compared for March, 2014 (**Figure 9**). This period was selected because data from two ADCP surveys were also available during this period. These data were used for the discharge, flow split, and velocity calibration (discussed below in **Sections 3.1.2, 3.1.3 and 3.1.4**).

Figure 9 shows that the model reproduces the observed characteristics of the water levels well. The tidal ranges, between the spring and neap tidal cycle, and times of high and low waters are well reproduced. The computed results generally had slightly lower peaks and higher troughs than the observed data, depending on the tidal conditions. For example, from March 21 to 24, 2014, the computed peak water levels are in very good agreement with the observed data, but the troughs are higher than the observed results. Whereas, from March 7 to 11, the troughs are in good agreement with the observed data, but the peaks are under-predicted.

Figure 9 Observed and Computed Water Levels for March, 2014 at (a) Point Atkinson, (b) Steveston, (c) Tunnel, (d) New Westminster, and (e) Port Mann

Table 2 shows the RMSE between the computed and the observed water levels at the five stations used for model calibration (**Figure 8**). The results show that the closer the location is to the upstream boundary, the less accurate the computed water level is. Therefore, the upstream boundary condition is likely a main contributor to the difference between the observed and computed water levels. The source of this discrepancy is likely due to the use of the flow output from the MIKE11 model as input to the SOG/LFR model at the upstream boundary. The Fraser River MIKE11 model was developed for predicting flood levels on the Fraser River. Hence, the model was calibrated using peak flow conditions on the Fraser River. In March 2014, the freshwater Fraser River discharge at Hope ranged from 600 to 1,200 m³/s, whereas flood conditions can result in discharges in excess of 10,000 m³/s. Thus, the MIKE11 model may not perform as well for low river discharges such as are observed in March 2014.

Table 2 Comparison of Observed and Computed Water Levels for March 2014

| Station | RMSE (m) |
|-----------------|----------|
| Point Atkinson | 0.20 |
| Steveston | 0.24 |
| Deas Island | 0.28 |
| New Westminster | 0.39 |
| Port Mann | 0.36 |

At the Tunnel (**Figure 9c**), the agreement with the observed water levels is generally within ± 0.3 m (RMSE = 0.28 m). Note that the water level and discharge at the Tunnel are strongly influenced by tidal levels, and vary rapidly as the tide rises and falls. In March 2014, the observed data at Deas Island show that the water level varied as much as 0.25 m in 15 minutes.

It should also be noted that a portion of the discrepancy in elevations is the result of approximations made in the formulation of the elevation boundary condition at Port Renfrew and Ballenas Island. The predicted tide elevation is a function of the moon and sun, while the observed tide elevation includes the influence of the moon and sun as well as local atmospheric conditions, which can play a major role at a given location and time.

3.1.2 Discharge

ADCP surveys were conducted by NHC and CRA Canada Surveys Inc. on March 7 and 27, 2014. The Fraser River flows at Hope were 770 and 880 m³/s on these two days, respectively. The survey program was designed to capture the tide and flow dynamics between the Main Arm, Ladner Reach, Sea Reach, and Canoe Passage. Six transects were surveyed on each day and the locations of these transects are shown in **Figure 10**. The March 7 survey was conducted during the period of falling tide (**Figure 11a**) and the March 27 survey was conducted during the period of rising tide (**Figure 11b**).

Figure 10 Location of ADCP Transects Conducted on March 7 and 27, 2014

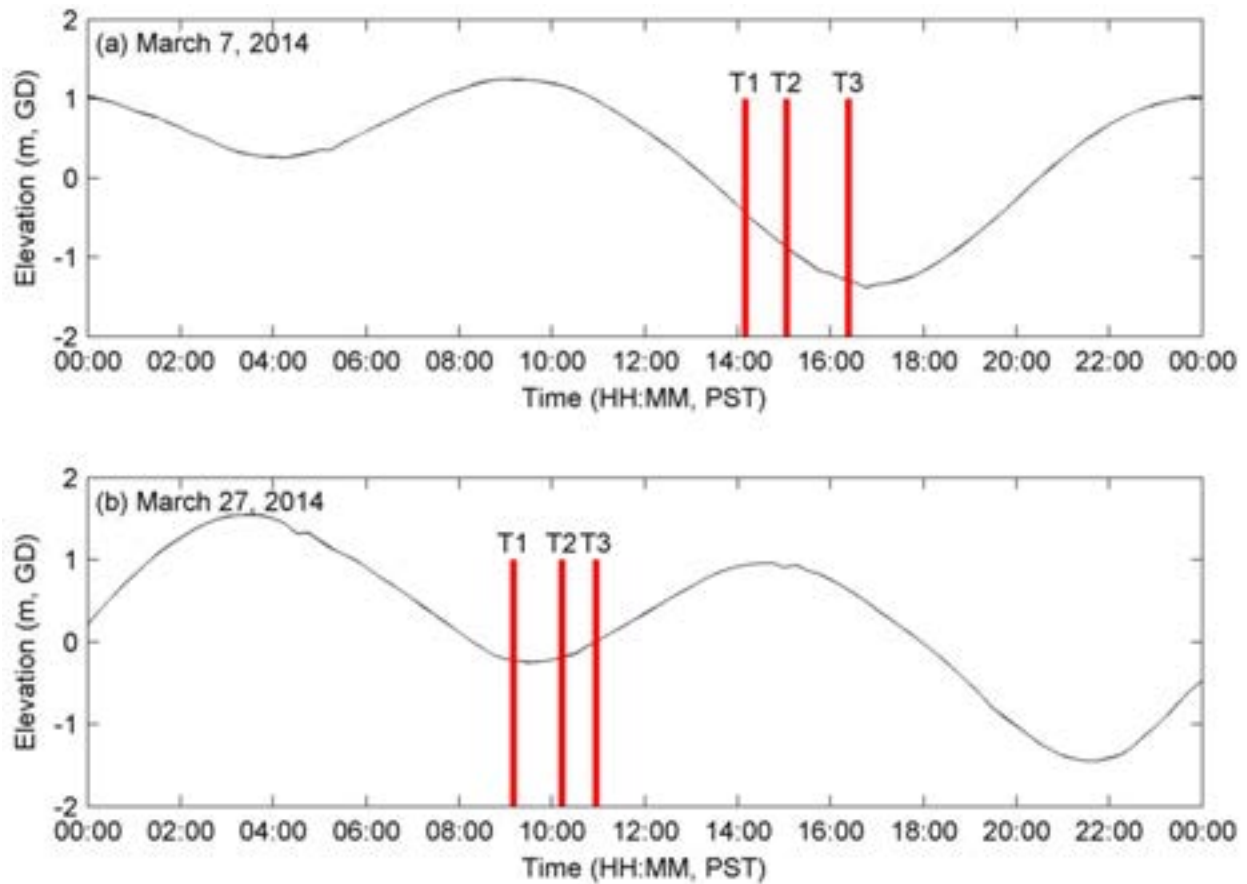

Figure 11 Observed Water Levels (black line) at the Tunnel for the Field Observations Conducted (a) March 7, 2014 and (b) March 27, 2014. The Time of Each Paired ADCP Transect is Marked T1 to T3.

The ADCP flow measurements and modelled results are compared in **Table 3**. The results show that the model under-predicted the discharge. This discrepancy is likely because the MIKE11 model was calibrated to peak flow conditions, whereas the ADCP measurements were taken during a low freshwater discharge (approx. 750 to 800 m³/s).

3.1.3 Flow Splits

A series of river training structures influence the flow conditions in the lower Fraser River and several large islands split the main channel. Also, as the Fraser River nears the ocean, several distributaries branch out from the Main Arm. Flow split data from the March 7 and March 27 ADCP survey was used to confirm model's ability to compute the distribution of flow around islands, training structures, and into distributaries. Measured and computed flow splits are compared in **Table 4**, **Table 5**, and **Table 6**.

Table 4 Modelled and Measured Flow Split at Main Arm and Ladner Reach

| Date | Measured | | Computed | |
|------------|-------------------------|--------------|-------------------------|--------------|
| | Main Arm Woodward Reach | Ladner Reach | Main Arm Woodward Reach | Ladner Reach |
| 2014-03-07 | 91% | 9% | 91% | 9% |
| 2014-03-27 | 88% | 12% | 89% | 11% |

Table 5 Modelled and Measured Flow Split at Ladner Reach, Sea Reach and Canoe Passage

| Date | Measured | | Computed | |
|------------|-----------|---------------|-----------|---------------|
| | Sea Reach | Canoe Passage | Sea Reach | Canoe Passage |
| 2014-03-07 | 81% | 19% | 62% | 38% |
| 2014-03-27 | 75% | 25% | 63% | 37% |

Table 6 Modelled and Measured Flow Split at Main Arm and Sea Reach

| Date | Measured | | Computed | |
|------------|-------------------------|-----------|-------------------------|-----------|
| | Main Arm Woodward Reach | Sea Reach | Main Arm Woodward Reach | Sea Reach |
| 2014-03-07 | 93% | 7% | 93% | 7% |
| 2014-03-27 | 90% | 10% | 95% | 5% |

The results show that there is good agreement between measured and computed flow splits from Main Arm (Transect 1a) into Main Arm – Woodward Reach, and Ladner Reach (Transect 1b) (**Table 4**).

At the split from Ladner Reach (Transect 2a) into Sea Reach (Transect 2b) and Canoe Passage (**Table 5**), the model predicts a greater fraction of the flow will exit through Canoe Passage than the observed data. Note that the observed flows in Ladner Reach (Transects 2a) were relatively small: 788 and 549 m³/s. The mouth of the Canoe Passage is strongly influenced by ocean conditions and the water levels and flows vary rapidly as the tide rises and falls. Thus, ADCP flow measurements are sensitive to the time they were taken and this could contribute to the difference between the observed and modelled flow split percentages. In addition, maintenance dredging took place in Ladner Reach in the spring of 2014. The model bathymetry did not

account for this recent event and this could have some effect on the flow split dynamics at Canoe Passage confluence. Measured and computed flows from Main Arm – Woodward Reach (Transect 3a) and Sea Reach (Transect 3b) into Main Arm – Steveston were in good agreement (**Table 6**).

The flow split results confirm that the model is, in most cases, accurately distributing the flow around islands, training structures, and into distributaries.

3.1.4 Velocity

Velocity measurements from the March 7 and March 27 ADCP survey were used to confirm model's ability to reproduce velocity distribution across the river channels. At each transect, the three-dimensional ADCP velocity measurements were depth-averaged over the water column. Depth-averaged transverse velocity profiles were extracted from the model results at the same locations and times as the ADCP measurements (**Figure 12** and **Figure 13**). The measured and computed velocities generally compared well, with the model tending to slightly under-predict velocities. The underestimate in velocity is likely a result of the underestimation in discharge imposed at the upstream boundary, predicted by the MIKE11 model as discussed in **Section 3.1.1**.

The velocity results show that the model reproduces the velocity distribution across the various river channels reasonably well. Exceptions are Transect 1b, where the flow enters Ladner Reach. A training structure extends upstream of Kirkland Island, which results in complicated flow patterns on its downstream side as the flow enters Ladner Reach. While the model does not capture these flow patterns particularly well, it does accurately predict the distribution of flow between the Main Arm and Ladner Reach (**Table 4**).

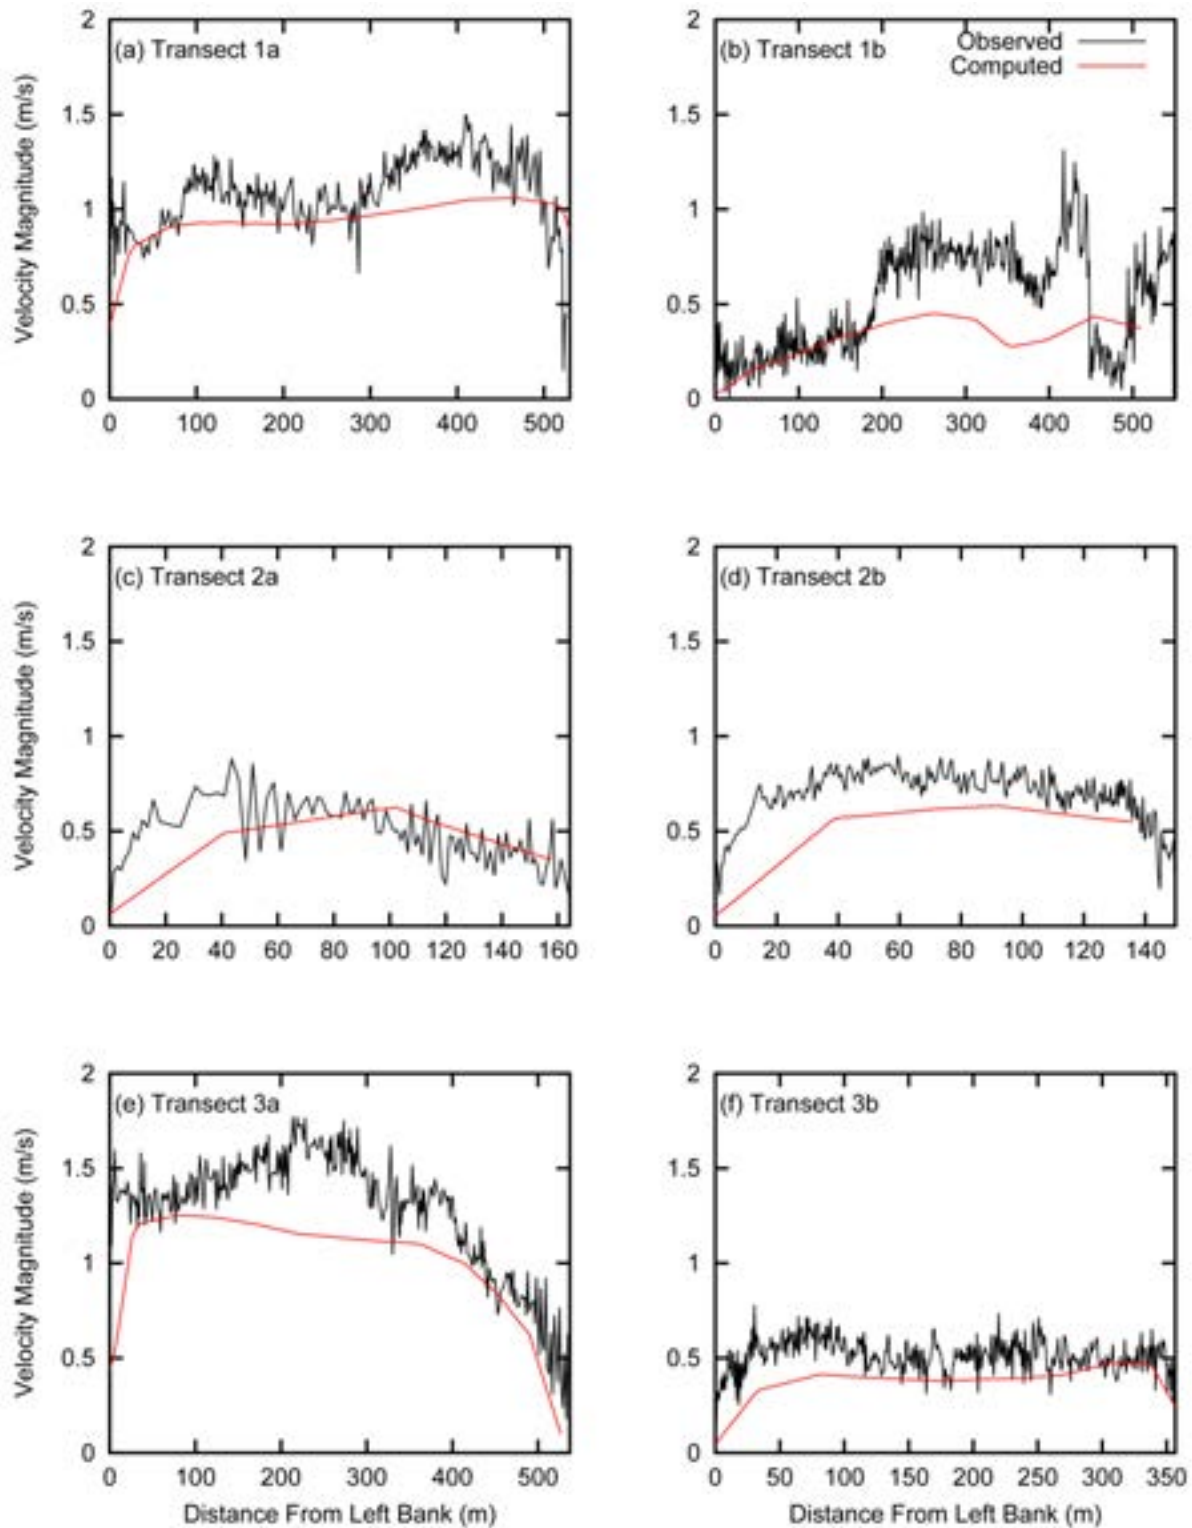

Figure 12 Depth-Averaged ADCP Velocity Measurements and Computed Results for March 7, 2014

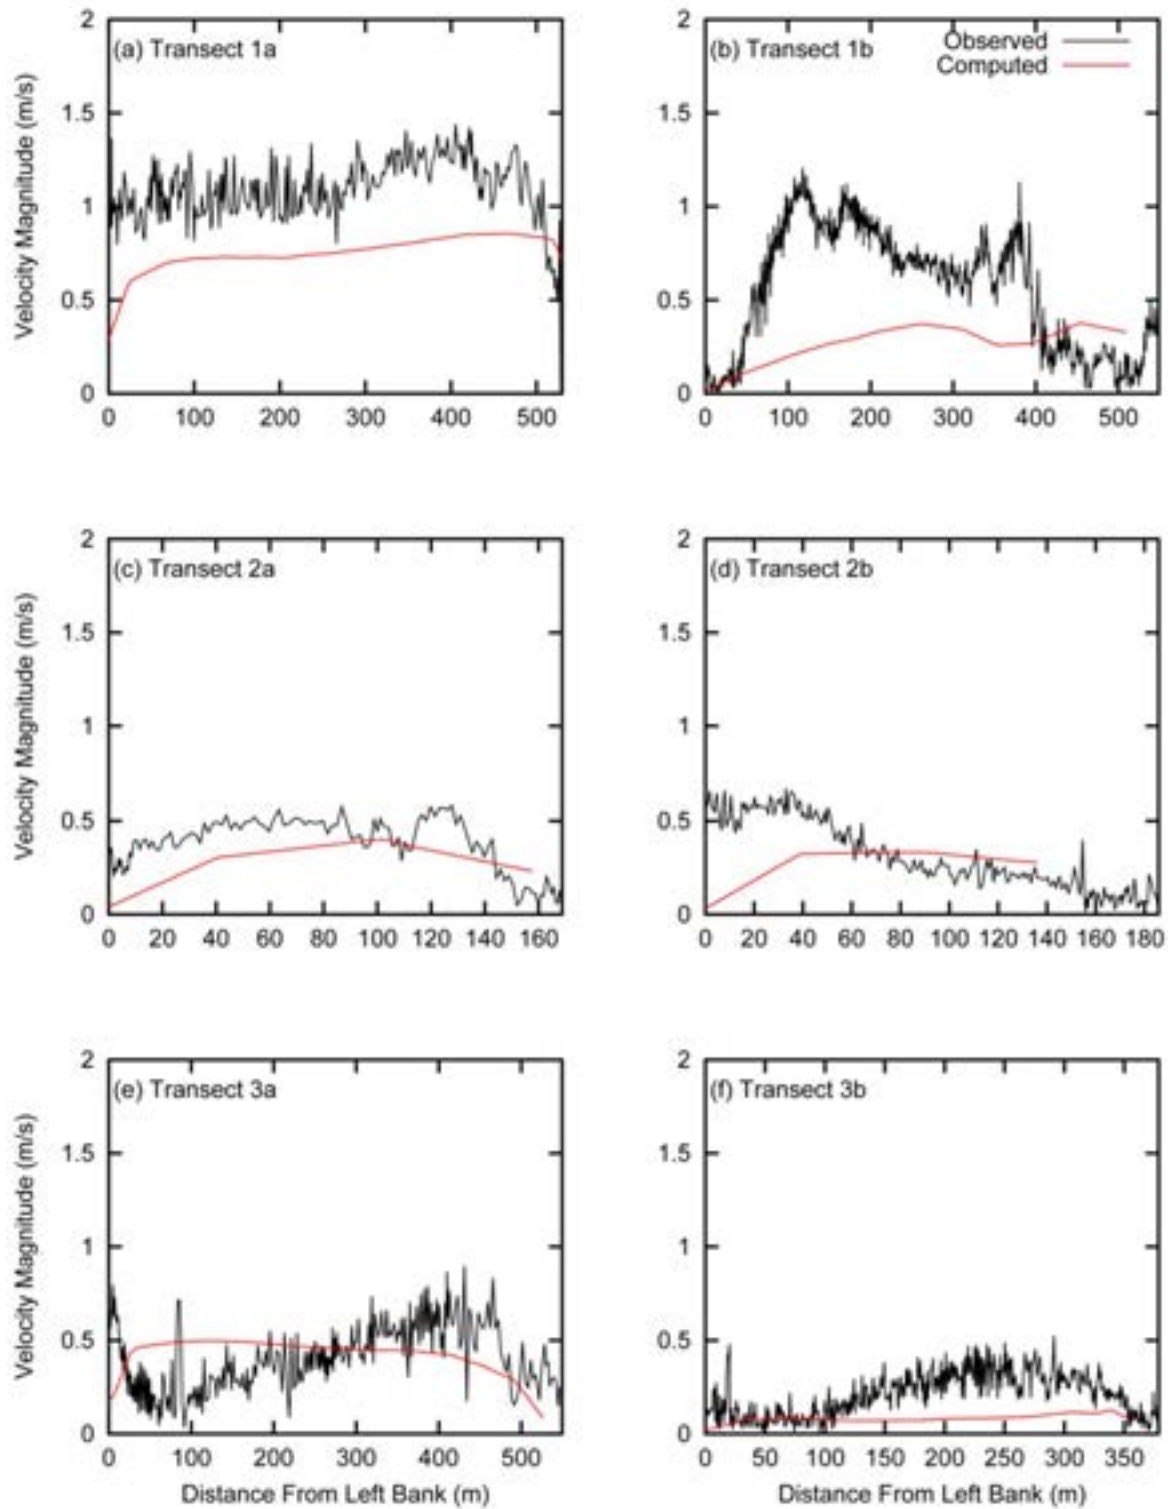

Figure 13 Depth-Averaged ADCP Velocity Measurements and Computed Results for March 27, 2014

3.1.5 Morphodynamic Model Validation

A coupled hydrodynamic–morphodynamic model was developed to provide hydraulic and scour/deposition information for lower Fraser River. TELEMAC's morphodynamic module, SISYPHE, computes changes in bed elevation by using the hydrodynamic information from the TELEMAC-3D model. The new bed elevations computed by SISYPHE are fed back into TELEMAC-3D to re-compute the flow hydrodynamics.

The coupled hydrodynamic–morphodynamic model results were compared to observed datasets to validate the morphodynamic component of the model. The model validation was divided into two parts. The first part was to demonstrate the ability of the model to predict the migration and infilling of a trench. The modelled results were compared to experimental data from van Rijn (1986). The migration and infilling of the trench, resulting from the Tunnel removal, is one of the key morphodynamic processes present in the study area. Therefore, the ability of the model to simulate trench migration is important in evaluating the potential effects of the Project. The second part of the morphodynamic model validation was to compare the modelled results to measured sediment loads and sedimentation patterns on the lower Fraser River.

3.1.5.1 Trench Migration Validation

Trench migration was simulated using TELEMAC's morphodynamic module, SISYPHE. The computed results were compared to experimental data presented in van Rijn (1986). The purpose of this modelling was to evaluate the performance of SISYPHE in simulating trench migration and infilling.

The results from the trench migration simulations were compared to the experimental data measured in a flume of length 30 m, height 0.7 m and width 0.5 m in the Delft Hydraulics Laboratory (van Rijn, 1986). The laboratory tests were carried out using sand of $D_{50} = 160 \mu\text{m}$, $D_{90} = 200 \mu\text{m}$ supplied at a rate of $q_s = 0.04 \text{ kg/s/m}$ (total load) to maintain equilibrium conditions in the upstream section of the trench. The mean flow velocity and water depth at that section were $u_0 = 0.51 \text{ m/s}$ and $h_0 = 0.39 \text{ m}$ during all tests. The trench dimensions were varied using initial side slopes of 3H:1V, 7H:1V, and 10H:1V. **Figure 14** shows a schematic of the numerical model setup based on the experiments by van Rijn (1986).

Figure 14 Problem Definition Sketch

Figure 15 shows the computed bed levels after 15 hours. The computed bed levels are in good agreement with the measured values. The maximum depth of the trench is predicted very well by the model. **Figure 15b** shows that the computed results slightly under-predict the infilling of the trench at the upstream end and that the trench does not migrate as far downstream as in the laboratory experiments. For all the trenches, the computed results slightly over-predict the infilling at the downstream end of the trench as it migrates downstream.

Overall, the model accurately predicts the migration and infilling of the trench over a range of trench geometries. This demonstrates the robustness of the model and suggests that it can be applied to problems with a range of geometries. The trench resulting from the Tunnel removal is expected to have initial side slopes of approximately 4H:1V on the upstream slope and 5H:1V on the downstream slope, as shown in the as-built drawings in **Attachment B**. These slopes are similar to those modelled in the trench migration validation simulations presented herein. While these flume experiments are not necessarily representative of the field conditions in the study area, the validation shows that the model is in agreement with the theoretical understanding of how an alluvial channel will respond to an excavated trench.

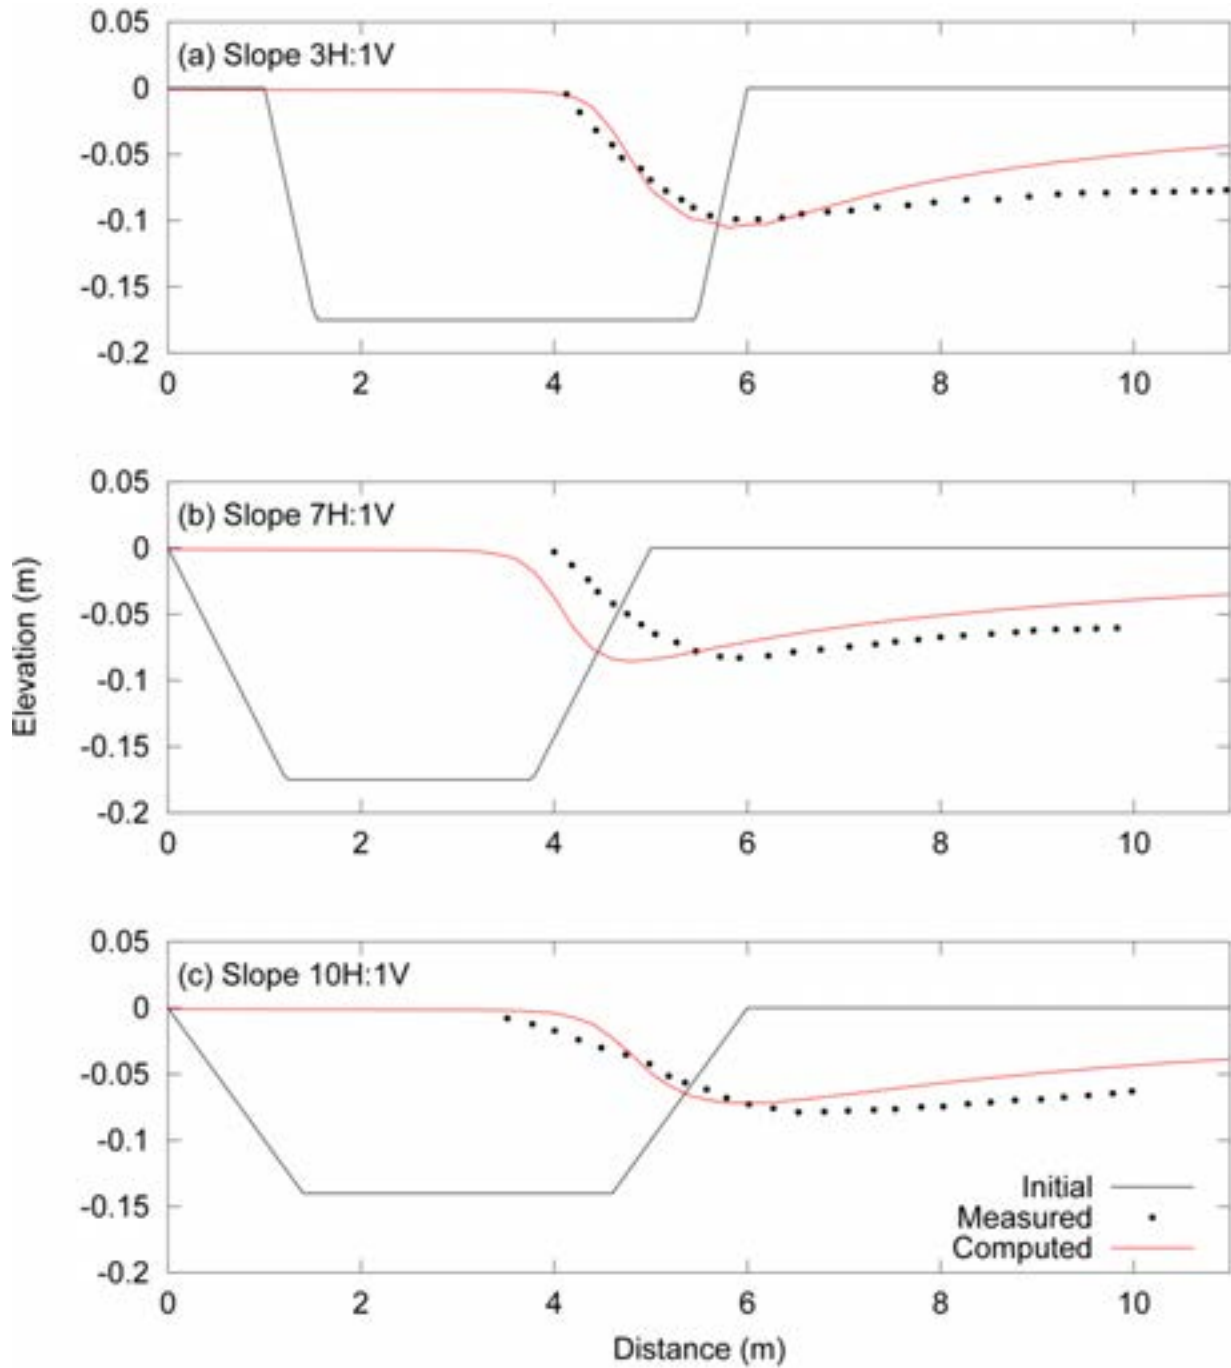

Figure 15 Computed and Measured Bed Level Profiles after 15 Hours for a Trench Initially Sloping at (a) 3H:1V, (b) 7H:1V, and (c) 10H:1V

3.1.5.2 Sediment Loads

In the lower Fraser River, fine sediments (also called washload) generally remain in suspension and therefore have little effect on sedimentation patterns. Of primary importance is the bed-material load, which is composed of the bed load and the fraction of sediment load capable of depositing in the river. This is the fraction of sediment that exerts an influence on river morphology and corresponds most closely with the modelled sediment sizes. Sediment loads on the lower Fraser River were measured by WSC at Hope, Agassiz, Mission, and Port Mann during the period 1965 to 1986. Based on that data, the bed-material load averaged 2.9 million tonnes/year, and ranged from 1.2 million to 8.9 million tonnes/year (NHC 2002).

Modelled sediment input over the course of the freshet period (May 26 to July 27) was 9.3 million m³ or about 15.3 million tonnes. This value is substantially larger than the long-term average bed material load of 2.9 million tonnes/year. However, the 2012 freshet was a large event with a return period of 20 years at Hope (WSC gauge 08MF005), and would have had a substantially higher than average sediment load. The largest measured bed material load occurred in 1972, and was 8.9 million tonnes. Peak flows and freshet timing and duration were comparable for 2012 and 1972, as shown in **Figure 16**.

In general, numerical models can be expected to predict sediment loads within an order of magnitude. The model has performed well by calculating a bed material load within approximately 70% of the measured value in a comparable year. This provides confidence that the morphodynamic model can be used for its intended purpose of analysing the effect of a particular change in the river (i.e. Tunnel removal); however, it should not be used to predict future sediment transport quantities or patterns.

Figure 16 Fraser River Daily Discharge at Hope (WSC 08MF005) for the Years 1972 and 2012

3.1.5.3 Sedimentation Patterns

Model results were compared to observed sedimentation patterns on the lower Fraser River. The validation run began with 2013 PWGSC bathymetry (conditions as of March 2013) and used the 2012 freshet hydrograph. This period was selected because of availability of data for hydrodynamic model calibration and because of its relatively large freshet flow (1:20 year return flow). The freshet period during which the Hope flows were greater than 6,000 m³/s, an estimated threshold for significant sediment motion in the Fraser River, was chosen for the sedimentation analysis. For the 2012 freshet, this period was between May 26th and July 27th (**Figure 16**). **Figure 17** shows the sedimentation pattern in the lower Fraser River at the end of the simulation on July 27th.

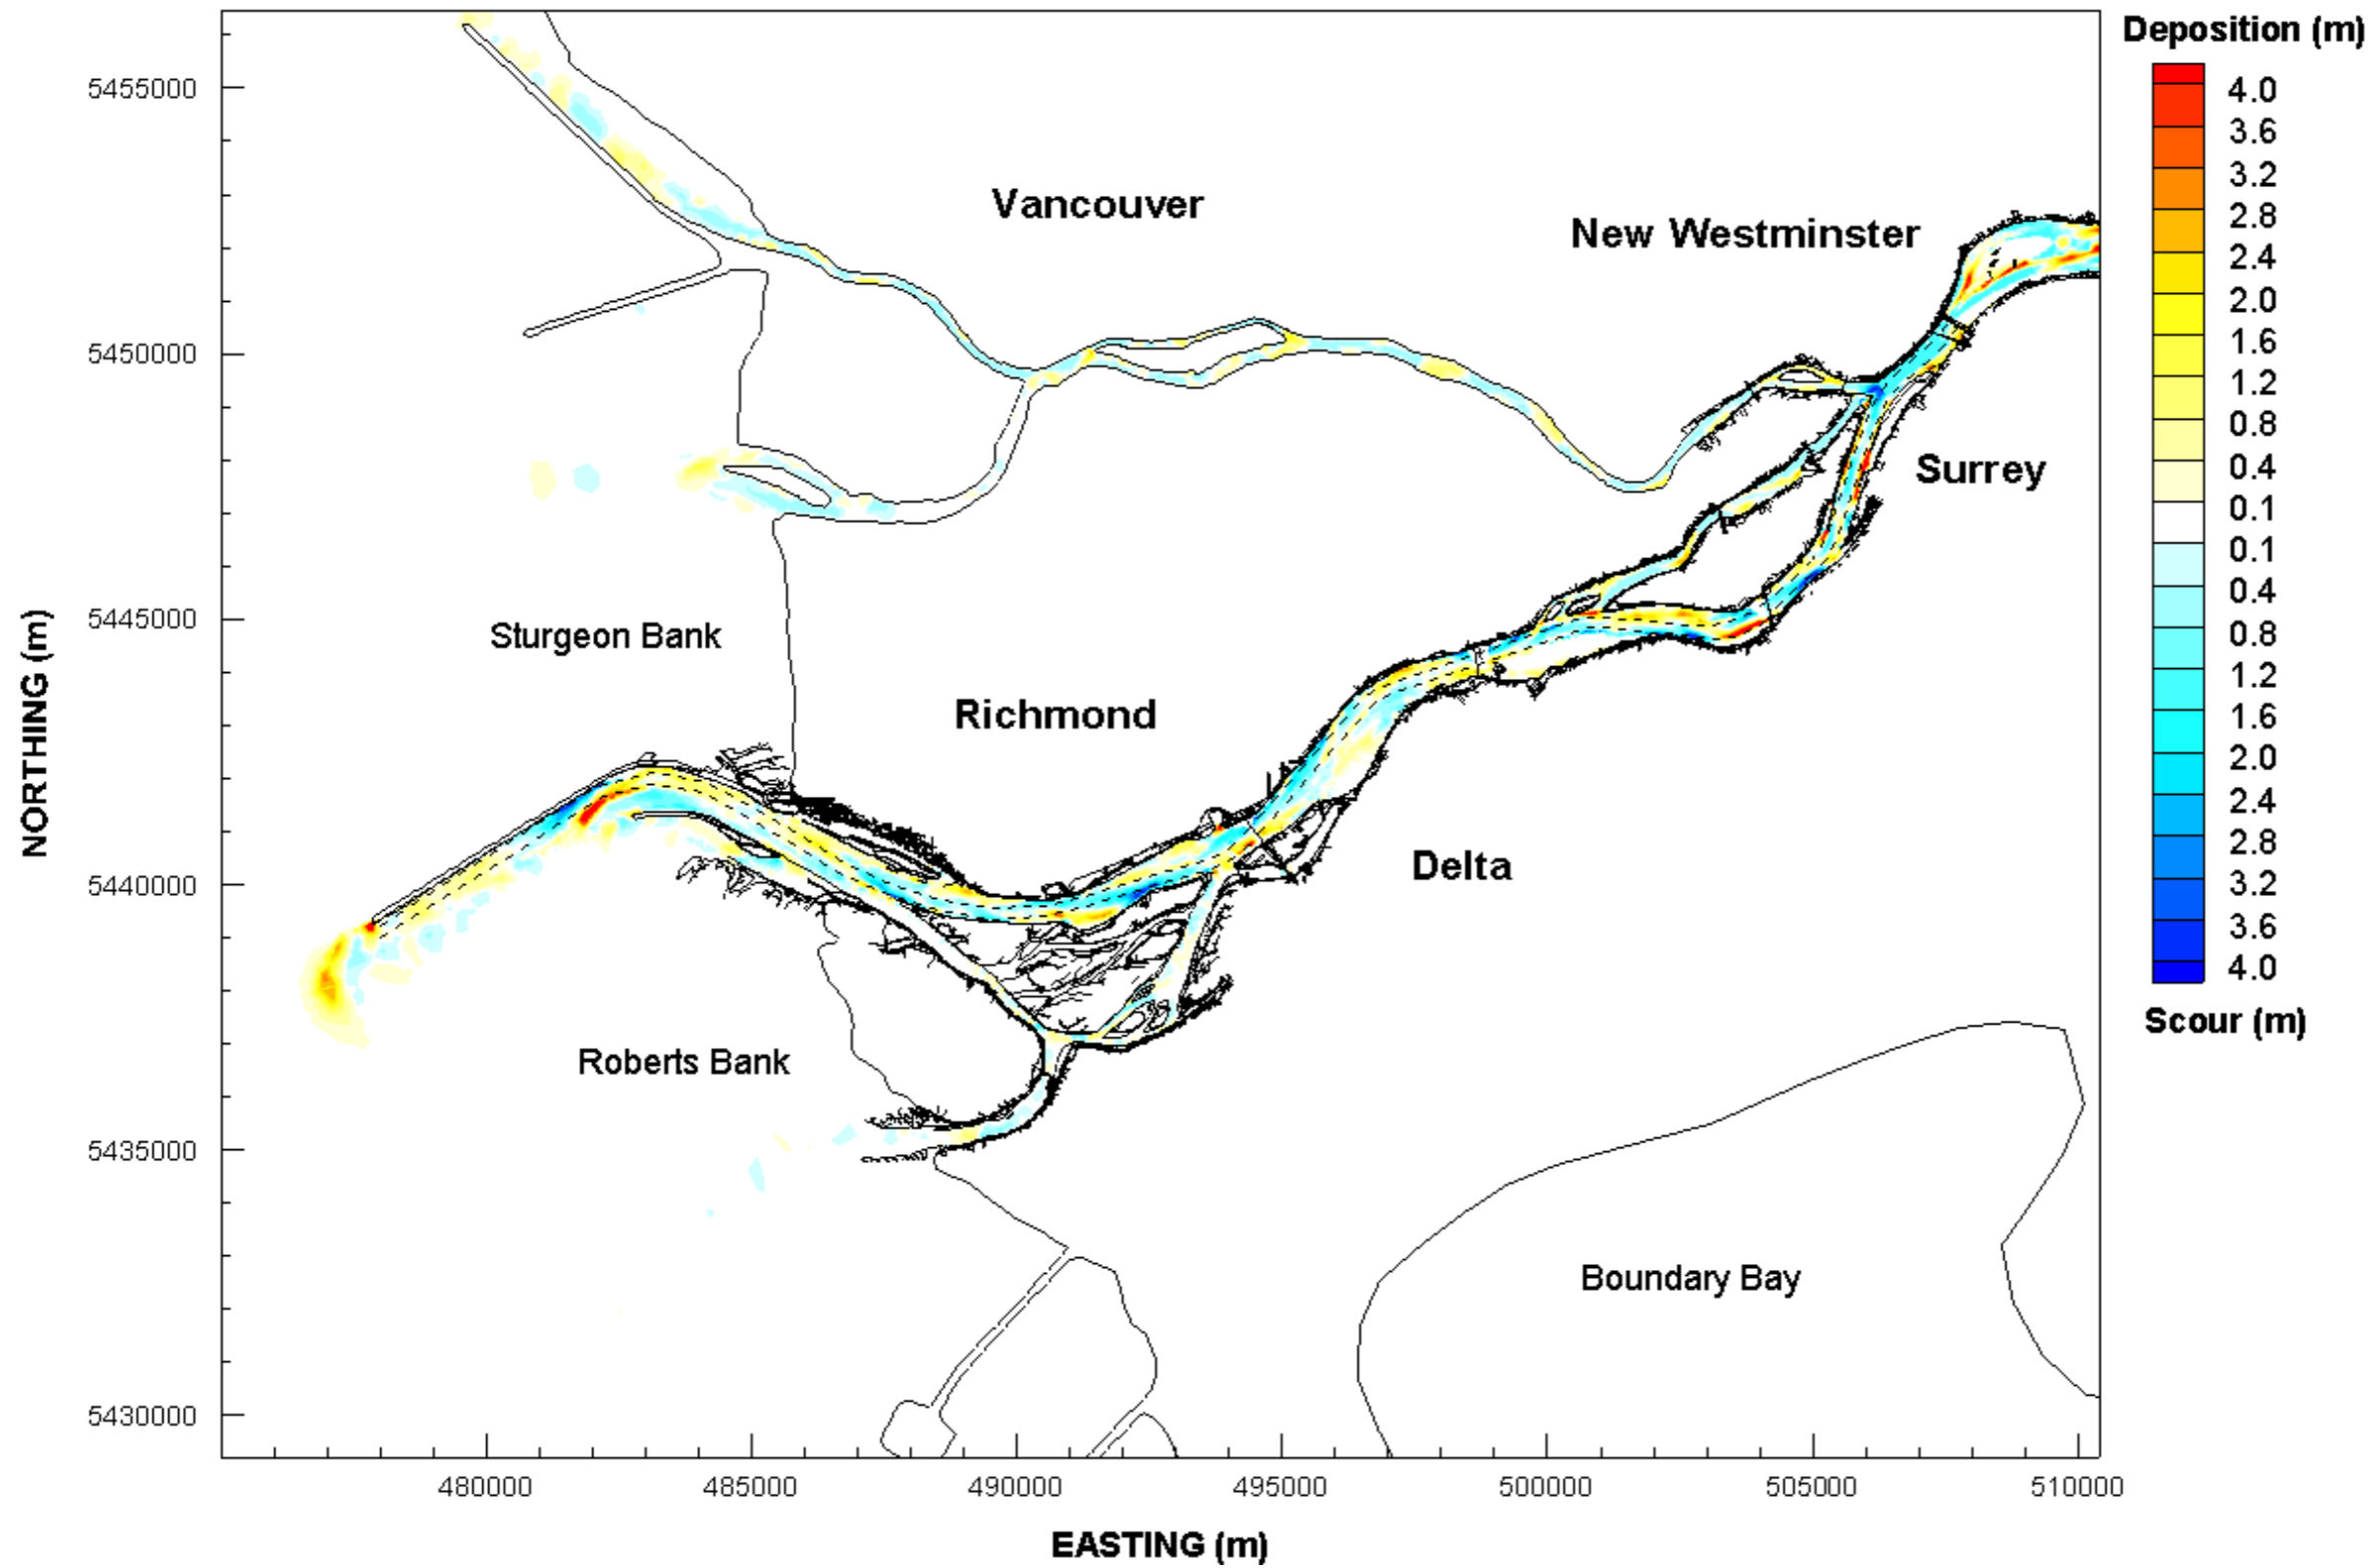

Figure 17 Scour/Deposition Map for 2012 Hindcast Simulation

The hindcast sedimentation pattern shows a good agreement with the established sedimentation patterns in the lower Fraser River, including the following attributes:

- Shoaling in the navigation channel in Sand Heads Reach between km 2 to km 4
- Shoaling on the south side of the navigation channel in Sand Heads Reach between km 4 to km 5
- Scour in the Steveston Jetty bend between km 5 to km 7
- Deposition along Steveston Cut between km 7 to km 12
- Scour along Kirkland Island between km 13 to km 14
- Deposition on the outer bend of St. Mungo's Bend between km 27 to km 30
- Deposition at the Fraser Surrey Dock (km 33)

Another approach to validating the morphodynamic model is through examining the shoaling rate in the system. Accurate shoaling rates for the lower Fraser River are expensive and time consuming to determine because of the necessity to conduct hydrographic surveys on a regular basis over an extended period of time. When no data on shoaling rates are available, it may be possible to substitute with dredge records. However, comparing the modelled dredge volume with the available dredge record from Port of Vancouver (PoV) was problematic. The PoV data are based on the dredging activity that takes place over the course of the standard calendar year (January to December), whereas the modelled dredge volume accounts for the volume required to be removed from the river in order to meet the design grade over the course of the dredging calendar (mid-June to mid-March). Spot dredging also takes place over the course of the freshet to keep the channel safe, but is not accounted for in the model simulation.

Despite the difficulties inherent in comparing the model results with the dredge record, the two should follow similar trends. Based on recent PoV dredge records (2006 to 2012), the annual dredging volume ranged between 2.4 and 3.1 million m³; the average annual dredging volume was 2.8 million m³. The modelled maintenance dredging volume² for 2012 was similar, at 2.5 million m³, providing confidence that the model adequately captures the sediment dynamics in the lower Fraser River.

² The current deep-sea shipping channel in the Fraser River is designed to accommodate vessels with a maximum draught of 11.5 m. Required maintenance dredging volume is computed by comparing the bed surface elevation at the end of the simulation to the design grade - the minimum dredge depth that allows an 11.5 m draft vessel to safely transit under the lowest high tide. If the modelled bed surface elevation is shallower than the design grade, then dredging is required.

3.2 No.5 Road Model Validation

The No.5 Road model results were compared to the following datasets:

- Observed water levels at the Tunnel
- Computed water levels at the Tunnel using the SOG/LFR model
- Velocity measurements from March 7th and March 27th, 2014 ADCP surveys

3.2.1 Water Levels

Within the extents of the No.5 Road model, WSC operates one continuous water level gauge at the Tunnel. This WSC hydrometric station was used to calibrate the No.5 Road model.

Observed and computed water levels were compared for March, 2014 (**Figure 18**).

Figure 18 Observed and Computed Water Levels at the Tunnel for March 2014

Computed and observed water levels at the Tunnel were compared. Overall, the model reproduced the observed water levels well. The computed water levels were generally within ± 0.2 m (RMSE = 0.17 m) of the observed values, which is less than the error for the SOG/LFR model (RMSE = 0.28 m). This suggests that using the No.5 Road model, which has a smaller computational domain, will not result in an increased level of error compared to the larger SOG/LFR model. Thus, the No.5 Road model can be used to investigate the local conditions in the vicinity of the project site with a higher resolution than would be practical using the SOG/LFR model.

3.2.2 Velocity

Results from the No.5 Road model were compared to the observed velocity measurements along Transect 1a for the ADCP surveys conducted on March 7 (**Figure 19**) and March 27 (**Figure 20**), 2014. The computed results capture the same features observed in the ADCP surveys; for example, the region of higher velocity in the north (right) half of the channel (**Figure 19**). The model tends to under-predict the velocity near the free-surface and over-predict the velocity near the bed. Possible reasons for the differences in the vertical velocity distribution include density stratification due to the Fraser River salt wedge (not considered in the model), wind action on the free-surface, or the model requiring a higher spatial resolution in the vertical direction. The depth-averaged velocity in **Figure 21** shows that while there are differences in the vertical velocity distribution, the depth-averaged velocity across the channel is well-represented.

4.0 Summary

A coupled hydrodynamic–morphodynamic model was developed to provide hydraulic and scour/deposition information for lower Fraser River. The model results were compared to observed water levels; discharge, flow splits and velocity measurements; laboratory experiments of trench migration; and sediment loads and dredging records on the lower Fraser River. The validation results demonstrate that the model is capable of reproducing the characteristics of the water levels, tidal conditions, river currents and sedimentation patterns.

1.0 Underwater Noise Modelling

Computational acoustic models were used by JASCO Applied Sciences Ltd. to predict the noise footprints of Tunnel decommissioning and bridge construction activities. The appendix presents the results of this modelling as well as the assumptions made regarding construction scenarios, equipment types, and source noise levels.

1.1 Modelled Construction Noise Scenarios

Acoustic modelling was conducted for six construction scenarios as summarized in **Table 1** to help predict Project-related changes in underwater noise levels within Fraser River South Arm, and Deas and Green Sloughs: impact pile driving; vibratory pile driving; vibrodensification; removal of sediment overlying the Tunnel; lifting one Tunnel segment; and Tunnel decommissioning involving simultaneous sediment removal, rip-rap removal, and lifting of a Tunnel segment. All modelling scenarios considered the influence of bathymetry and riverbed geoacoustics on waterborne sound propagation.

Table 1 Specifications of Modelled Construction Scenarios

| Scenario | Description | Noise Source(s) | Source Coordinates |
|----------|---|-----------------------|--------------------------------|
| 1 | Impact hammer driving of a cylindrical pile along the edges of Deas Slough | Impact hammer | 49° 6.911' N 123° 4.082' W |
| 2 | Vibratory hammer driving of a cylindrical pile along the edges of Deas Slough | Vibratory hammer | 49° 6.911' N 123° 4.082' W |
| 3 | Vibrodensification in Deas Slough | Vibrodensifier | 49° 6.911' N 123° 4.082' W |
| 4 | Cutter suction dredging at Tunnel crossing | Cutter suction dredge | 49° 7.292' N 123° 4.562' W |

1.1.1 Construction Activities Excluded from the Model

The modelling focused on construction activities expected to generate underwater sound levels that would exceed the existing background ambient noise. Activities such as separation of the bulkhead connections between Tunnel segments may require the use of specialized equipment. Potential effects of underwater noise generated by such equipment will be assessed using sound data collected during Tunnel decommissioning and mitigation measures will be put in place to manage such effects as appropriate.

1.2 Source Noise Levels for Construction Activities

1.2.1 Impact and Vibratory Driving of Cylindrical Piles

Underwater acoustic sound generated from impact and vibratory driving at the pile wall was predicted using JASCO's pile driving source model (MacGillivray 2013). The forcing function (the applied force from the hammer versus time) at the top of the pile is related to the proposed hammer type and hammer energy. The forcing function was modelled with the GRLWEAP 2010 model (Pile Dynamics Inc. 2010), which includes a large database of various hammers and associated manufacturers' specifications.

The predicted forcing function was coupled to a one-dimensional finite-difference model to account for the vibrational coupling between the pile and the surrounding water and sediments. The pressure radiating from the pile wall was computed using a vertical array of individual sources (monopoles) distributed along the pile to account for the boundary condition between the pile wall and surrounding water. A typical impact hammer for the two-metre diameter steel pipe piles was selected based on a review of existing hammers and on a discussion with the Project engineers. The impact hammer type that was modelled (a Delmag D100-13 with a rated energy output of 360 kJ) was chosen based on communication with the Project engineers and a review of existing hammer types used in North America for the proposed pile diameter, length, and pile materials. Based on the manufacturer's specifications, the impact hammer was assumed to operate at 35 blows per minute at the maximum hammer energy (Hammer & Steel 2014). The vibratory hammer type that was modelled was an APE-400B with a rated power output of 738 kJ. **Table 2** shows the pile dimensions and hammer specifications that were used in the GRLWEAP and JASCO pile driving models to compute source levels for both impact and vibratory pile driving.

Table 2 Engineering Specifications of Pile Driving Equipment

| Hammer Method | Pile Size (diameter x length) | Hammer Type | Hammer-Energy (kJ) | RAM Mass (tons) | Blows Per Minute |
|---------------|-------------------------------|----------------|--------------------|-----------------|------------------|
| Impact | 2 m x 85 m | Delmag-D100-13 | 360 | 10.01 | 35 |
| Vibratory | 2 m x 85 m | APE-400B | 738 | 0.35 | - |

Sound levels were computed for distances of up to 100 m from the source (i.e., far-field source levels) by propagating the pressure field of each individual monopole source from the pile driving source model out to 100 m range using JASCO’s Full-Waveform Range-dependent Acoustic Model (FWRAM; see **Section 1.3.1**). The 1/3-octave band received levels were then back-propagated to the standard one-metre reference range using transmission loss that was computed with JASCO’s Marine Operations Noise Model (MONM; see **Section 1.3.2**). Sound levels from the pile-driving scenarios described in **Table 1** were then modelled with MONM using the far-field source levels.

The 1/3-octave band far-field source levels for the impact hammer are shown in **Figure 10**. The broadband source level for this activity is 220 dB re 1 $\mu\text{Pa}^2\text{s}$ at 1 m. The forcing function modelled with GRLWEAP for this hammer, and the monopole source spectra for impact pile driving sampled at three different depths, are shown in **Figure 11** and **Figure 12** respectively.

The 1/3-octave source levels for the vibratory hammer are shown in **Figure 13**. The estimated broadband source level for this activity is 217 dB re 1 μPa at 1 m. The forcing function with GRLWEAP for this hammer is shown in **Figure 14**. The monopole source spectra for vibratory pile driving sampled at three different depths are shown in **Figure 15**.

1.2.2 Vibrodensification

Source levels for vibrodensification were obtained from measurements taken by JASCO at the Roberts Bank Terminals, B.C. (Austin 2007). The maximum of the two measurements in each 1/3-octave band between 10 Hz and 40 kHz were used. Source levels above 40 kHz were extrapolated using the trend between 20 and 40 kHz. The broadband source level for the vibrodensifier used in this modelling study was 182 dB re μPa at 1 m. The modelled 1/3-octave band source levels are shown in **Figure 13**. The modelled source depth for vibrodensification was taken to be at mid-water column (2.5 m).

1.2.3 Sediment Removal to Facilitate Tunnel Decommissioning

Source levels for cutter suction dredging operations to remove sediment overlying the Tunnel were derived from measurements of a cutter suction dredge obtained by JASCO for the Deltaport Third Berth project (Zykov et al. 2007). Source levels were extrapolated above the maximum measured frequency of 40 kHz using the trend between 20 and 40 kHz. Sounds below 1 kHz were assumed to originate from inside the dredge hull, whereas sounds above 1 kHz were assumed to originate from the cutter head at the riverbed (Robinson et al. 2011). The source depth for the dredge hull was modelled at 2.14 m below the water surface; the source depth of the cutter head was modelled at one metre above the riverbed. The modelled broadband source level of the cutter suction dredge was 182 dB re 1 μ Pa and **Figure 13** shows the modelled 1/3-octave band source levels.

Source levels for clamshell dredging associated with Tunnel decommissioning were based on published measurements of two dredges (Miles et al. 1987, Dickerson et al. 2001). Where measurements were presented as received levels at a specified distance rather than source levels at a reference of one metre, source levels were back-propagated using environment-based transmission loss modelling. Averaged 1/3-octave band source levels were then selected for the dredge. The source depth for the clamshell dredge was set to half the local water depth since losses due to bottom and surface interactions will be less for a source at mid-depth than for a source near the seafloor or surface. The modelled broadband source level of the clamshell dredge was 176 dB re 1 μ Pa. **Figure 13** shows modelled 1/3-octave band source levels.

1.2.4 Tug and Barge Operations

Tugs and barges will be used to support cranes and dredging operations during Project construction. The river tug *Seaspan Venture* was identified as a representative barge-towing vessel, based on a discussion with the Project engineers and a review of similar vessels currently operating in the Fraser River. Source levels for the river tug were estimated from measurements, performed by JASCO, of a harbour tug transiting at 7.5 kts near Roberts Bank terminals (Warner et al. 2013). Source levels for the river tug were reduced by 5.7 dB to account for the difference in total engine power between it and the larger, measured harbour tug (**Table 3**). **Figure 13** shows the modelled 1/3-octave band source levels for river tugs. The broadband source level was 166 dB re 1 μ Pa at one metre. Source levels were extrapolated below 20 Hz using a constant value equal to the 20 Hz 1/3-octave band level.

Table 3 Tugboat Specifications

| Type | Length | Width | Draught | Source depth | Total engine power (kW) |
|-------------|--------|-------|---------|--------------|-------------------------|
| Harbour tug | 30 m | 13 m | 3.17 m | 1.47 m | 4.476 |
| River tug | 19.5 m | 7 m | 3.17 m | 1.47 m | 1.268 |

It was assumed that all construction barges will be towed by tugs. Barges might, however, have vibrating machinery onboard that could conduct a small amount of underwater sound into the river through the barge’s hull. When sound from tug and barge operations was modelled, it was assumed that the barge contribution was not substantial compared to sound generated by the tugs’ propulsion systems.

1.3 Sound Propagation Model

1.3.1 Full-Waveform Range-Dependent Acoustic Model

JASCO’s Full-Waveform Range-dependent Acoustic Model (FWRAM) was used to simulate pulse propagation to produce synthetic waveform traces of the impact pile driving pulses. These calculations were used to determine the rms and peak pulse pressure as a function of range from the source, and consequently the range-dependent conversion factor between SEL and rms SPL.

FWRAM computes synthetic pressure waveforms at receiver locations on a range-depth grid using Fourier synthesis to generate full-waveform sound field predictions in finely spaced frequency bands at the individual frequencies. Environmental inputs for FWRAM include bathymetry, water sound speed profiles, and physical properties of the riverbed (geoacoustic profiles).

1.3.2 Marine Operations Noise Model

Sound levels were modelled using MONM, which predicts underwater sound propagation in range-varying acoustic environments. MONM computes acoustic fields in three dimensions by modelling transmission loss (TL) along evenly spaced two-dimensional (2-D) radial traverses covering a 360° swath from the source, an approach commonly referred to as $N \times 2$ -D. The model fully accounts for depth and range dependence of several environmental parameters, including bathymetry and sound speed profiles for the water column and the sub-bottom sediments. It also accounts for the additional reflection loss at the riverbed that is due to partial conversion of incident compressional waves to shear waves at the riverbed and sub-bottom interfaces through a complex density approximation (Zhang and Tindle 1995).

The acoustic environment is sampled at a fixed-range step along radial traverses. MONM treats frequency dependence by computing acoustic TL at the centre frequencies of 1/3-octave bands. Broadband received levels are summed over the received 1/3-octave band levels, which are computed by subtracting band TL values from the corresponding source levels. MONM's predictions have been validated against experimental data from several underwater acoustic measurement programs (Aerts et al. 2008, Funk et al. 2008, Ireland et al. 2009, O'Neill et al. 2010, Warner et al. 2010, Hannay et al. 2013). For this study, MONM was used to compute TL for 1/3-octave bands centred between 10 Hz and 5 kHz. To model non-pulsed sources such as vibrodensification, tugs, dredgers, and vibratory pile drivers, MONM was used to predict the SPLs on the $N \times 2$ -D grid. For impact pile driving, MONM was used to model the single-strike SELs.

The transmission loss computed by MONM was further corrected to account for the attenuation of acoustic energy by molecular absorption in water. The volumetric sound absorption is quantified by an attenuation coefficient, expressed in units of decibels per kilometre (dB/km). The absorption coefficient depends mainly on the sound frequency, but also on the temperature, salinity, and hydrostatic pressure of the water. In general, the absorption coefficient increases with the square of frequency. The absorption of acoustic wave energy has a noticeable effect (>0.05 dB/km) at frequencies above 1 kHz. At 10 kHz, the absorption loss over 10 km can exceed 10 dB.

Transmission loss was approximated for bands between 6.3 and 50 kHz by using the TL computed at 5 kHz and applying the correct frequency-dependent absorption coefficient in each band. In this study, the absorption coefficients were calculated based on water temperature at 10°C and salinity of 0.5 parts per thousand and a water depth of 2.5 m.

Sound levels were modelled at eight different receiver depths from 2.5 m to the riverbed, distributed vertically in the water column. Modelled received levels were gridded separately in each horizontal plane (i.e., at each modelled receiver depth). To generate a conservative estimate, the modelled results were obtained by collapsing the stack of grids into a single plane using a maximum-over-depth rule, which means that the sound levels at each planar point are taken to be the maximum value from all modelled depths in the water column for that point.

1.3.3 Calculation of Peak SPL, rms SPL, and SEL for Impact Pile Driving

For pulsed sound sources, MONM computes per-pulse SEL in 1/3-octave bands, but does not directly predict the 90 per cent rms SPL or peak SPL. Although the 90 per cent rms SPL and peak SPL are easily measured in situ, these metrics are generally more difficult to model than per-pulse SELs. In addition, the adaptive integration period to model rms SPLs, implicit in the definition of the 90 per cent rms SPL, is highly sensitive to the specific multipath arrival pattern from an acoustic source and can vary greatly with distance from the source or with receiver depth. Nonetheless, per-pulse SEL and SPL are related, and SEL can therefore be used to estimate SPL.

In this study, FWRAM was used to calculate peak SPL and rms SPLs for impact pile driving. The pressure field from the pile driving source model was modelled at frequencies from 10 Hz to 2 kHz in 0.5 Hz steps to generate synthetic pressure waveforms along a single transect. These waveforms were then analyzed to determine peak SPL and rms SPL as a function of range from the source. The representative transect, which extended 1.2 km from the source, heading 268 degrees west, was chosen for its uniform bathymetry.

The FWRAM pulse length and waveform predictions were used to derive a range-dependent conversion function between SEL and rms/peak SPL. The resulting conversion functions were applied to the per-pulse SEL predictions from MONM to compute the rms SPLs and peak SPLs. The conversion functions for per-pulse SEL to rms SPL and peak SPL are shown in **Figure 16** as a function of source-receiver offset.

Long-term exposures to high-intensity anthropogenic noise can temporarily or permanently reduce an animal's hearing sensitivity. Cumulative sound exposure is generally measured as the total sound energy an organism receives over some period. The cumulative SEL for impact pile driving was computed for sequences of pile driving blows that could occur over 24 hours. The number of strikes required to drive each pile is not known, so three durations of pile driving activity were modelled over a 24-hour period for each scenario (see **Table 1**): one minute, 10 minutes, and 100 minutes.

1.3.4 Calculation of Sound Level Contours

The predicted received SPLs and SELs were contoured to show the estimated acoustic footprint for each scenario. Sound level contours were converted to GIS layers, visible on maps of the study area. For each duration scenario, the 95th percentile radius ($R_{95\%}$) and the maximum radius (R_{\max}) for each sound threshold level were tabulated.

1.4 Environmental Parameters

1.4.1 Bathymetry

High-resolution bathymetry data within several kilometres of the Tunnel, collected as part of the river hydraulics and river morphology study for the Project, were used to develop a bathymetry model for the study area. Water depths in the Fraser River vary depending on tidal cycle and time of year. High-water conditions are most conservative with respect to the distance that sound propagates in the water because sound energy is more rapidly absorbed by bottom sediments in shallow water. Therefore, the data were adjusted to a high-water datum of 2.0 m to accommodate high-water stands during the fall and winter months. Maximum water depths in the study area are less than 30 m. Bathymetry data were re-projected onto a 10 m x 10 m grid in UTM zone 10 N for use with MONM.

1.4.2 Water Depth

Water depths in the river vary depending on the tides and the time of year (seasonal variations). High-water conditions are most conservative with respect to the distance that sound propagates in the water. Therefore, the data were adjusted to a high-water level of 2.0 m to accommodate high-water stands during the fall and winter.

A water depth of five metres, which corresponds to a high high tide, was assumed for modelling pile driving along the edge of Deas Slough. Much of the actual Project-related construction along the edge of Deas Slough would occur under lower water conditions or in the dry with low tide. Effectiveness of construction pads with granular fills as a way to mitigate underwater noise was investigated, subsequent to completion of modelling. Propagation through the granular fill and the underlying soils is expected to attenuate sound levels generated by pile driving and reduce underwater noise emissions. Given these considerations, levels of underwater noise emissions generated by the actual construction are expected to be somewhat lower than the results of the modelling presented in this document.

1.4.3 Geoacoustic Properties

Sound propagation is influenced by the physical properties of the river bottom sediments, including the density, compressional wave (P-wave) speed, shear wave (S-wave) speed, compressional wave attenuation, and shear wave attenuation of the riverbed sediments. The main riverbed sediment types in the study area are water-saturated silts and silty sands, based on borehole and penetration data (Puar 1996). The geoacoustic properties for these types of sediments (**Table 4**) were estimated on empirical formulas presented by Hamilton (1980).

Table 4 Geoacoustic Parameters used for Modelling the Riverbed Sediments

| Depth below seafloor (m) | Sediment type | Density (g/cm ³) | P-wave speed (m/s) | P-wave attenuation (dB/λ) | S-wave speed (m/s) | S-wave attenuation (dB/λ) |
|--------------------------|---------------|------------------------------|--------------------|---------------------------|--------------------|---------------------------|
| 0–3 | Clayey silt | 1.5 – 1.4 | 1537 – 1523 | 0.18 | 180 | 2.0 |
| 3–29 | Silty sand | 1.4 – 1.6 | 1523 – 1529 | 0.18 – 0.20 | | |
| >29 | Sandy silt | 1.6 | 1529 | 0.20 | | |

1.4.4 Sound Speed Profile

The sound speed profile in the water column was derived using the empirical Marczak equation (Marczak 1997) or fresh water. The estimated sound speed in water at the study location is approximately 1,457 m/s based on the average water temperature of 10°C from late summer to early spring. Average seasonal water temperature values were obtained from the DFO Fraser River Environmental Watch Report (DFO 2013).

2.0 Noise Source Modelling Results

It was assumed that impact pile driving would operate at 35 blows per minute, totalling one minute (35 blows), 10 minutes (350 blows), and 100 minutes (3,500 blows) during a 24-hour period. Under that assumption, 15.4 dB, 25.4 dB, and 35.4 dB were added to the single-pulse SEL to yield 24-hour SEL results. **Table 5** presents the 95th percentile contour radii of 24-hr (one-, 10-, and 100-minute piling) SEL unweighted and M-weighted (pinnipeds) contours for impact pile-driving (scenario 1). Corresponding contour maps of unweighted and M-weighted SEL are provided in **Figure 1** through **Figure 3**. The M-weighting curves reduce sound at low and high frequencies; however, the pinniped M-weighting curve is nearly flat over the frequency range generated by the impact hammer. In **Table 5** and **Table 6**, $R_{95\%}$ is the radius of a circle centred at the source that encompasses 95 per cent of the area ensounded to the threshold value; R_{max} is the maximum distance from the source to the given noise threshold in any direction.

Table 5 Radii (95%), of 24-hr (1-, 10-, and 100-minute Piling) Unweighted SEL and M-weighted SEL Contours for Impact Pile Driving (Scenario 1)

| SEL (dB re 1 $\mu\text{Pa}^2\cdot\text{s}$) | 1 min | 10 min | 100 min |
|--|-------|--------|---------|
| FHWG threshold fish < 2 g (183 dB) ¹ | 91 | 286 | 698 |
| FHWG threshold fish \geq 2 g (187 dB) ¹ | 69 | 169 | 602 |
| Southall M-weighted pinniped threshold (186 dB) ² | 66 | 180 | 618 |

Notes: radii measured in metres

The broadband (10 Hz to 50 kHz) rms SPL radii for the NMFS injury threshold (190 dB re 1 μPa) was computed with 53 m, based on the estimated offset curves described in **Section 1.3.3**. The corresponding contour map of rms SPL is provided in **Figure 4**, including the contours for the ZAA for the 50th (L_{50}) and 95th (L_{95}) exceedance percentiles. **Table 6** presents the peak SPL radii to injury thresholds for scenario 1. The 95th percentile radius for the ZAA extends to 7,460 m for both L_{50} and L_{95} .

Table 6 Radii (Rmax) of Peak SPL Injury Thresholds for Impact Pile Driving (Scenario 1)

| Acoustic Injury Criteria | Peak SPL (dB re 1 μPa) |
|--|------------------------------------|
| FHWG Fish < 2 g (206 dB) ¹ | 53 |
| B.C. MPDCA Threshold Fish (210 dB) ¹ | 42 |
| Southall M-weighted Pinniped Threshold (218 dB) ² | 27 |

Notes: radii measured in metres

Table 7 presents 95th percentile and maximum contour radii for vibratory pile driving (scenario 2), vibrodensification (scenario 3), cutter suction dredging (scenario 4), tug and barge activity during crane lift of Tunnel segments (scenario 5), and simultaneous dredging at Tunnel crossing and crane lift of Tunnel segments (scenario 6). Corresponding contour maps for unweighted maximum-over-depth broadband (10 Hz to 50 kHz) rms SPLs in dB re 1 μ Pa are shown in **Figure 5** to **Figure 9**. The grey and black contours indicate the ZAA for L_{50} and L_{95} . The 95th percentile radii at 120 dB re 1 μ Pa rms SPL are 951 m in Deas Slough, and 2,746 m in the Fraser River South Arm. The maximum radii for the ZAA extend to 5,500 m and 6,250 m for L_{50} and L_{95} , respectively (**Table 8**).

Table 7 Radii (95%) of Unweighted rms SPL Contours for Scenarios 1 through 6 (All Distances in Metres)

| rms SPL (dB re 1 μ Pa) | Scenarios | | | | | |
|-------------------------------|-----------|-----|-----|------|-----|------|

Glossary

| Term | Definition |
|---------------------|---|
| alevin | A newly hatched salmonid that is still attached to the yolk sac. |
| anadromous | Migrating from sea to freshwater to spawn. |
| bed material load | Sediment that is transported by river flow along the river bottom and comprises particles found in appreciable quantities in the channel bed. |
| Blue-listed | The B.C. CDC designation for species considered to be of special concern (formerly vulnerable) in British Columbia. |
| crown closure | The proportion of the sky hemisphere obscured by vegetation when viewed from a single point. |
| detritus | Organic matter produced by the decomposition of organisms. |
| epibenthic | Living above the bottom (also demersal). |
| escapement | The number of salmon arriving at their natal river or stream to spawn (or the number of salmon that have escaped fisheries and are available to spawn). |
| fecundity | The potential reproductive capacity of an organism (e.g., the number of eggs a fish produces during each reproductive cycle). |
| fry | A young fish at the post-larval stage. |
| Highway 99 corridor | The right-of-way owned by the Province of B.C. for Highway 99 from the Peace Arch Canada–U.S. border crossing in Surrey to the Oak Street Bridge in Richmond. |
| intertidal | Aquatic habitat between the mean lowest low water level and the mean highest high water level. |
| mesohabitat | Basic structural features of a river or stream such as pools, backwaters, runs, glides, and riffles. |
| Project alignment | The spatial extent within which Project components and related activities are proposed. |
| Red-listed | The B.C. CDC designation for species considered extirpated, endangered, or threatened. |
| salt wedge | Freshwater from a river floats on top of seawater in a layer that gradually thins toward the sea. The denser seawater moves upstream along the bottom of the river estuary, forming a wedge-shaped layer that is thinner as it moves upstream. A difference in velocity occurs between the two layers that acts against the mixing tendency of tide- and wind-induced turbulence. |

| Term | Definition |
|-----------|--|
| smolt | A young salmon that first migrates from freshwater to the sea. |
| thalweg | From a longitudinal view, the deepest part of a riverbed from the source to the mouth; the deepest point in any given river cross-section. |
| wash load | Sediment that moves in suspension in the river flow but is not represented in the bed of the channel. |

1.0 Scope of Study

This technical volume presents the objectives, methods, and findings of the fish and fish habitat study undertaken to support the environmental assessment of the George Massey Tunnel Replacement Project (Project).

A review of the available information and the state of knowledge pertaining to fish and fish habitat in the study area was undertaken. Field studies were undertaken in 2014 to supplement and update existing information. This appendix provides a synthesis of the literature review and 2014 field studies. A summary of study components, objectives, and scope is provided in **Table 1-1**.

Table 1-1 Study Components and Major Objectives

| Component | Objective | Scope |
|--------------------------|--|---|
| Literature review | Determine fish habitat values and freshwater fish species' use of watercourses within the study area. Supplement and update existing information within the study area. | Comprehensive information review of available fish and fish habitat inventory information within the study area. |
| Freshwater fish sampling | Verify and update available information on freshwater fish species' use of watercourses within the study area. | Fish sampling in spring and autumn within a subset of sites, to supplement existing information. |
| Fish habitat assessment | Assess the quality of freshwater fish habitat in watercourses within the study area. | Assessment of physical fish habitat features and water quality in all watercourses and water features within the study area, with a focus on larger, higher-value watercourses. |

2.0 Review of Existing Literature and Data

Information on fish species occurrence and distribution, hydrology and hydraulics of major watercourses, and a description of fish habitat characteristics (i.e., riparian vegetation, streambed type, water quality) within the study area was compiled from the following literature sources:

- Fisheries Information Summary System (FISS 2014)
- B.C. Species and Ecosystem Explorer (B.C. CDC 2015)
- Species at Risk Public Registry (Government of Canada 2013)
- Committee on the Status of Endangered Wildlife in Canada (COSEWIC) (Government of Canada 2014)
- Fraser River Estuary Management Program – Burrard Inlet Environmental Action Program Habitat Atlas (BIEAP - FREMP 2014)
- Delta Watersheds: Fish and Amphibian Distributions Map (Delta 2003a)
- Delta Fish and Amphibians Study: 2000–2003 Sample Site Locations Map (Delta 2002)
- Delta Timing Schedules for Instream Works Map (Delta 2003b)
- Corporation of Delta Online Mapping System – DeltaMap (Delta 2012)
- City of Richmond Interactive Map (Richmond 2014)
- Consultant reports, e.g., Vancouver Airport Fuel Delivery Project EAC Application (VAFFC 2011a) and Addendum (VAFFC 2011b)
- Topographic and resource maps, air photos, and forest cover maps
- Biologists and habitat technicians from Fisheries and Oceans Canada (DFO), and B.C. Ministry of Forests, Land and Natural Resource Operations (MFLNRO)
- iMapBC (DataBC 2014)
- Government papers and technical reports sourced through the DFO Library online catalogue (WAVES), Canadian Science Advisory Secretariat publications, and the Government of B.C. Cross-linked Information Repositories
- Periodical journal articles and theses sourced using Google Scholar, ScienceDirect, Web of Science, University of B.C. cIRcle, JSTOR, and EBSCOhost

- Ongoing consultation with the following groups:
 - Aboriginal groups with an interest in the Project, based on asserted traditional territories or treaty settlement lands
 - Municipal and regional environmental staff who operate in the study area
 - Local naturalist groups, streamkeeper groups, salmon enhancement volunteers, streamside residents, and fishers
 - Parks staff and staff of other recreational organizations

3.0 Methods

3.1 Study Area

The study area includes all watercourses (e.g., rivers, streams, sloughs, and ditches) located adjacent to or that intersect Highway 99 and are within 30 m of the Project alignment, as well as other watercourses located within the same study area width within the broader Highway 99 corridor between Bridgeport Road in Richmond and Highway 91 in Delta. At the Fraser River South Arm, as well as Deas and Green sloughs, the study area extends to a width of 500 m on either side of the Project alignment (**Appendix A, Figure 1a**).

For major water features within the study area, information pertaining to fish presence and fish habitat, including basic water quality data, is relatively well-documented. Field sampling therefore focused on upland channelized watercourses (ditches) where fish presence and fish habitat values were largely unknown. Sampling occurred at representative sites at approximately one-kilometre intervals along ditches that parallel Highway 99, and in ditches that intersect the Highway 99 right-of-way (ROW). Given the relatively uniform nature of the typically low-gradient, channelized ditches, this sampling is representative to characterize fish species presence and to assess fish habitat values.

3.2 Temporal Scope

Fish and fish habitat sampling was undertaken in 2014 to document existing conditions in watercourses within the study area. Because water levels, water quality, and fish presence are expected to show appreciable variation seasonally, fish sampling was conducted in spring (March 31-April 1, April 15-16, and April 21-22) 2014 and autumn (October 15-16, 18-19, and 19-20) 2014 to capture the widest range of conditions. Sampling during these time periods also maximizes the potential to document fish species that might be present on a seasonal basis, given anticipated poor water quality conditions during the summer months due to, for example, high water temperatures coinciding with low dissolved oxygen levels. Habitat assessments were primarily conducted during low flows and low water level conditions in the summer (July 14-16), complemented with additional observations during spring and autumn sampling. Water quality measurements were taken during all spring, summer, and autumn field sampling events to provide further information on fish habitat values.

3.3 Study Methods

3.3.1 Literature Review of Major Water Features

Information on hydrology and hydraulics, biophysical characteristics (i.e., fish habitat values, including riparian zone features), and fish use was compiled for the entire length of major watercourses (i.e., river, streams, and sloughs) within the study area. Fish habitat information, including the state of riparian vegetation and water quality data for major watercourses within the study area was complemented with data collected during the 2014 field studies.

3.3.2 Field Habitat Assessment

Aquatic habitat assessments were conducted for major water features and upland watercourses within the study area. It was determined during a review of existing information, and confirmed during spring sampling, that upland watercourses within the study area are relatively uniform in nature. Detailed on-site habitat assessments were therefore conducted at watercourses that appeared to be of higher value to fish, and at a subset of other ditches considered representative of other watercourses within the study area. This approach is consistent with field methods applied to similar studies undertaken in support of linear infrastructure projects in the Lower Mainland. The remaining ditches were assessed based on photographs taken in the field and imagery available online through online mapping services for Richmond, and Delta (Delta 2012, Richmond 2014).

Habitat assessments (both detailed assessments and those based on field photographs and online imagery) were conducted in accordance with Resources Information Standards Committee (RISC) prescribed and standardized guidelines for collection of fish habitat data. For the detailed on-site assessments, data were recorded using RISC site cards, digital forms created in iForm (spring sampling), and FlowFinity (summer and autumn sampling) software installed on an iPad. Photographs were taken of all assessed watercourses.

Approximately 100 m of each watercourse were surveyed at each detailed habitat assessment site. Existing conditions such as water flow, channel and morphological characteristics, and the presence of barriers to fish passage, were visually assessed and recorded. In addition, mesohabitats (pools, riffles, runs, glides) were described. The following physical attributes were measured at each site to characterize watercourse conditions and fish habitat:

- Stream stage (the amount of water passing through the channel)
- Channel and wetted width (m)
- Extent and type of instream fish cover

- Type and width (m) of riparian vegetation, and crown closure (per cent)
- Dominant and subdominant streambed materials
- Channel morphology, pattern, and confinement

Field crews investigated the connectivity of watercourses within the study area, and within approximately 100 m outside the study area boundaries. Habitat assessments were conducted primarily during low flows in the summer, but also complemented with additional observations during spring and autumn sampling.

3.3.3 Field In Situ Water Quality Assessment

Basic in situ water quality information was obtained at the majority of sites where fish sampling or habitat assessment was conducted, to better understand habitat values and habitat suitability for different fish species. Water quality parameters were measured at 25 sites in the spring during lead-up to freshet (June 1 per Government of Canada 2014b); 15 sites in the summer, during low flows; and 35 sites in autumn, during the beginning of the rainy season. Water quality parameters were collected using a YSI multi-parameter meter and included temperature (°C); dissolved oxygen (DO, in mg/L), conductivity (µS/m), and pH. The meter was calibrated according to the manufacturer’s instructions prior to each round of field sampling. Digital photographs were taken at each site to document conditions at the time of assessment.

Water quality results for temperature, DO, and pH were evaluated against *B.C. Water Quality Guidelines for the Protection of Aquatic Life* (B.C. WQG; B.C. MOE 2006) (**Table 3-1**). The results were used to help determine habitat suitability and likelihood of fish presence, including the potential seasonality of use.

Table 3-1 Evaluation Criteria for Water Quality Parameters

| Parameter | B.C. Water Quality Guidelines | Reference |
|---|--|---------------|
| Temperature (°C) (range) ¹ | ± 1°C change beyond daily water temperature range of 9 to 16°C | B.C. MOE 2006 |
| Dissolved oxygen (mg/L), (instantaneous minimum) ² | 5 | B.C. MOE 2006 |
| pH | 6.5 - 9.0 | B.C. MOE 2006 |

Notes:

¹ Dependent on salmonid species and life stage. This criterion captures the temperature range for rearing stages of salmonid species that have been previously documented in upland watercourses within the study area (i.e., cutthroat trout).

² Dependent on fish life stage. The instantaneous minimum concentration of DO for protection of aquatic life is 9 mg/L for buried embryo/alevin life stages and 5 mg/L for all other life stages. Because upland water features typically do not provide suitable spawning habitat for salmonids, the 5 mg/L criterion was used.

3.3.4 Fish Sampling

Information regarding fish presence, distribution, and relative abundance was obtained by conducting a desktop literature review of historic fish sampling records from watercourses within the study area (DataBC 2014, FISS 2014) and fish sampling using gee-type minnow traps in accordance with *Fish Collection Methods and Standards* (RIC 1997), and *Reconnaissance (1:20,000) Fish and Fish Habitat Inventory Standards and Procedures* (RISC 2001). Fish sampling was undertaken within a subset of sites where the literature review identified a gap in fish distribution data. Sampling locations were limited to smaller ditches and lesser sloughs within the study area. Fish presence in major watercourses within the study area (e.g., Fraser River, Deas Slough, and Green Slough) was described using existing published information (e.g., FISS, technical and government reports).

Minnow traps were set at 26 sites during the spring sampling session and 35 sites in the autumn session. Two to four traps were deployed per site, depending on the size of the watercourse and its connectivity and proximity to adjacent sampling sites. Traps were soaked overnight, for a period of approximately 24 hours (range: 18.5 to 24.6 hours). Fish were identified to the species level using freshwater fish species field keys (e.g., McPhail and Carveth 1999). Fish total length was measured to the nearest mm. When non-salmonid species were captured, minimum and maximum fish total length was recorded.

Minnow trapping was selected over other fish sampling techniques (e.g., backpack electrofishing) given the morphology and water quality in the majority of watercourses in the study area. Characteristically high conductivity and turbidity, along with easily disturbed fine bottom sediments, would have substantially reduced the effectiveness of electrofishing sampling.

3.3.5 Incidental Observations

Incidental captures of non-focal aquatic organisms (e.g., amphibians and invertebrates) were identified, recorded in field notes, and released in accordance with RISC guidelines for capturing and handling of live animals (B.C. MELP 1998, RISC 1998, B.C. MOE 2008).

3.4 Data Analysis

Field data were recorded electronically using electronic equivalent of RISC fish collection and habitat assessment forms created in iForm (spring sampling) and FlowFinity (summer and autumn sampling) software installed on an iPad. Data were wirelessly downloaded into a data management system and imported directly into a Microsoft Access database developed for the freshwater fish study program. Data from hardcopy field forms were entered manually into that database.

Geomatics data management was supported by the use of ESRI’s geographic information system (GIS) mapping software, specifically ArcSDE SQL server database and ArcGIS server web mapping software. The database information was cross-referenced with photographs and geographic coordinates. Inconsistencies were identified and reviewed to determine the cause of the discrepancy and, if necessary, discrepancies were reconciled

All determination of fish habitat quality and likelihood of fish species occurrence was qualitative (did not involve statistical calculations or modelling). Watercourses were classified based on commercial, recreational, and Aboriginal (CRA) fisheries values, as described in **Table 3-2**. Where the existing classification for a watercourse was insufficiently assigned or missing, watercourses were coded in accordance with the classification system described in **Table 3-2** with consideration of fish access, historic and recent fish sampling data, physical habitat characteristics, and water quality.

Table 3-2 Fish and Fish Habitat Study Watercourse Classification System

| CRA Fish Habitat Value | Coding | Description |
|---------------------------------|------------|---|
| Potential for CRA fish presence | Red | Year-round habitat for CRA or listed fish species (e.g., salmonids, eulachon (<i>Thaleichthys pacificus</i>), white sturgeon (<i>Acipenser transmontanus</i>), or green sturgeon (<i>A. medirostris</i>)) |
| | Dashed-red | Seasonal habitat for CRA or listed fish species (e.g., overwintering habitat for juvenile salmonids) |
| No CRA fish presence | Orange | Significant upstream source of food or nutrients to red or dashed-red habitat |
| | Yellow | Non-CRA fish bearing, but with no value to CRA or listed fish species (e.g., resident fish only) |
| | Green | No value for fish (CRA, listed, or other fish species) |

Notes: Watercourse classification was built upon existing municipal mapping (Delta 2003a, 2012, Richmond 2014), along with previous classification conducted for the Ministry during baseline studies for the South Fraser Perimeter Road Project (Coast River 2006). Existing classifications from municipal mapping provide a varying amount of detail, ranging from a binary description of potential salmonid presence (Richmond 2014) to classification schemes similar to that described in **Table 3-2** (Delta 2003a, Coast River 2006).

4.0 Results

This section presents the main findings of the literature review and field studies, and briefly describes data gaps, potential biases, and incidental observations.

4.1 Information Review of Previous Fish Sampling

The FISS (2014) documents fish presence in major catchments and some ditches within the study area (**Appendix B, Table 1**). Additionally, the Corporation of Delta (2002, 2003a) has assessed fish presence in the major Delta catchment areas FA-5, FA-4, BBA-2, BBA-3, and BBA-1 that overlap with the study area (**Appendix A, Figure 2**). Past sampling efforts in the vicinity of the Project have resulted in the capture of native and introduced resident fish species. A complete list of these species is provided in **Appendix B, Table 2**.

4.2 Study Results

The results of the literature review and field studies are presented below. Habitat assessment, water quality, and fish sampling results within upland ditches are also summarized. Data from all detailed habitat assessments are provided in **Appendix B, Table 3**. Representative photographs of all watercourses are presented in **Appendix C, Photos 1 through 112**. Water quality data are presented in **Appendix B, Tables 4, 5, and 6**. Fish capture data are provided in **Appendix B, Tables 7 and 8**.

4.2.1 Fraser River South Arm

In addition to the Fraser River South Arm, the study area includes several upland watercourses (**Appendix A**), the existing conditions of which are described below.

4.2.1.1 Hydrology and Hydraulics

The Fraser River is the largest river on the west coast of Canada, draining approximately 250,000 km² of mountainous terrain in southern B.C. (Kostaschuk and Luternauer 2004). Downstream of Hope, the Fraser River divides into a gravel reach and a sand reach, as determined by the dominant bed-load type (Rosenau and Angelo 2007). The gravel reach extends from Hope downstream to the Fraser River's confluence with the Sumas River near Mission. The sand reach spans downstream of the gravel reach, from the Sumas River confluence to the river mouth at Sand Heads (Rosenau and Angelo 2007).

At the New Westminster trifurcation off the eastern tip of Lulu Island, the lower Fraser River splits into three branches: the South Arm, which extends approximately 35 km to Sand Heads; Annacis Channel, which rejoins the South Arm a short distance downstream; and the North Arm, which further divides into the Middle Arm at the eastern tip of Sea Island near its mouth (**Appendix A, Figure 1a**).

The South Arm is an estuarine ecosystem influenced by the presence of a tidally driven salt water wedge that flows near the river bottom underneath a freshwater surface layer (Kostaschuk 2002). Mean annual river discharge at Port Mann Bridge (approximately 25 km upstream of the study area) is about 3,600 m³/s (Gray and Tuominen 1999). River flows fluctuate on an annual basis. Heaviest flows occur between May and July during freshet, with normal maximum flows exceeding 8,000 m³/s in June (NHC 2009). From December through March, flows are lower at approximately 1,450 m³/s (NHC 2009). Although dependent on discharge, tide level, bathymetry, and local control from training structures, the South Arm discharges on average approximately 85 per cent of the total river flow (Schaefer 2004).

From the Sumas River confluence downstream to the Fraser River mouth, the riverbed displays a series of deep pools, typically in the river bends and at locations where the river channel narrows. The water surface drops fairly uniformly with no apparent gradient to the riverbed (NHC and Triton 2006). Even during extreme flood conditions, the river gradient is approximately 5 cm/km, indicating that the water level is affected strongly by downstream control, rather than local hydraulic conditions (NHC and Triton 2006). Downstream of New Westminster, the South Arm has deepened appreciably in response to dredging, river training, and confinement by bridges and dikes. On average, bed levels in the South Arm have lowered by 0.1 m/year since the 1970s (NHC and Triton 2006).

The Fraser River transports an average of 17.3 million tonnes of sediment annually (measured at Mission, 84 km upstream of the river mouth), consisting of 35 per cent sand, 50 per cent silt and 15 per cent clay (McLean et al. 1999). Most of the sediment is transported during freshet through the South Arm (McLaren and Tuominen 1999). Heavier sand particles settle on the riverbed during transport; however, finer silt and clay are carried in suspension and deposited in the estuary. About 30 per cent of the sediment is delivered to Sand Heads at the mouth of the Fraser River (Williams et al. 2009). The riverbed in the South Arm is composed almost entirely of sand with a mean particle size of 0.25 mm to 0.35 mm, with little seasonal variation (Kostaschuk et al. 1989). During freshet, sand dunes form on the river bottom from sediment transported by the river. As the flow increases, the dunes expand in height and length, and migrate along the river bottom producing scour or fill as they move (NHC 2009).

The river channel width at the Tunnel crossing is approximately 570 m, measured from top of bank to top of bank. Bed levels in the vicinity of the Tunnel crossing have formed as a result of natural scour and deposition, as well as maintenance dredging occurring annually in the river mainstem. The greatest bed level changes seem to have occurred from 1988 through 1989 and 2000 to 2001. Upstream of the Tunnel, the main channel at the dam on Deas Slough experienced about two to four metres of local deposition, while at Deas Island, the river bed lowered by about three to four metres due to scouring. Downstream of the Tunnel crossing, the thalweg impinges on the left bank to the upstream third of Kirkland Island and there is evidence of bank scour. Between the Tunnel and the Lulu Island Delta Main, there is a hole at the left bank that was scoured by four metres between 1988 and 2000, and by lesser amounts in subsequent years. Corresponding deposition occurred immediately downstream of the scour hole. Local deposition also occurred in Ladner Harbour between 2001 and 2009.

4.2.1.2 Physical Fish Habitat

The shoreline of the Fraser River South Arm is characterized by a variety of shore-based industries (e.g., lumber mill; grain, forest products, and rolled paper distribution) and shipping terminals (e.g., Fraser Wharves, Annacis Auto Terminals, Fraser Surrey Docks) (FREMP 2006). The New Westminster trifurcation training structure, which serves to decrease sedimentation, thus reducing dredging requirements, is within this river segment, approximately 15 km upstream of the Tunnel (FREMP 2006).

Despite channeling to minimize sedimentation, annual maintenance dredging (hopper and cutter suction) occurs at several locations within this segment (FREMP 2006, PMV 2014a). Within St. Mungo's Bend and Annieville Channel, upstream of the study area, regular dredging occurs to allow access by large vessel traffic (FREMP 2006). Infrequent and localized clamshell dredging also takes place to maintain boat and barge access, access to small craft harbours, and moorage (FREMP 2006).

Productive shoreline habitat in the Fraser River South Arm downstream of the trifurcation is generally confined to a narrow band of intertidal marshes, mud- and sandflats around Tilbury Island, along the north and south banks of Annacis Channel, and along the Fraser River banks on the southwest side of Annacis Island (BIEAP - FREMP 2014). Given the extensive industrial activity along the shoreline of the South Arm, a high proportion of habitat is classified as of low (green-coded) or moderate (yellow-coded) productivity (BIEAP - FREMP 2014).

Shoreline habitats along the South Arm and their respective FREMP (2014) designations within the study area include the following (also see **Appendix A, Figure 3**):

1. Low productivity (green-coded) riprap armouring is located on the north bank of the South Arm, upstream of the Tunnel crossing. A short section (approximately 55 m) of shoreline on the north bank just upstream of the Tunnel crossing was designated as high productivity (red-coded) habitat, following works to compensate for disturbance associated with riverbank erosion protection undertaken in 1987. Compensation works included the creation of an intertidal bench that was incorporated into a riprap slope. A narrow strip of upland deciduous woodland, dominated by black cottonwood (*Populus trichocarpa*), backs the armoured shoreline by the Tunnel crossing.
2. Riprap armouring offering habitat of moderate productivity (yellow-coded) is located on the north bank of the South Arm, downstream of the Tunnel crossing. A narrow strip of upland vegetated areas, consisting of grass and deciduous woodland dominated by black cottonwood, backs the armoured shoreline downstream of the Tunnel crossing. Compensation works have been undertaken also within this section of shoreline. Riparian habitat, intertidal marsh, and subtidal riverbed habitat were created in 2005 to compensate for disturbance of riparian and in-river habitat associated with the Deas Refit Complex Expansion Project.
3. Shrub and deciduous tree woodland, predominantly black cottonwood, fronted by moderate productivity (yellow-coded) sandflat habitat is located on the south bank of the South Arm (north bank of Deas Island), upstream and downstream of the Tunnel crossing. A small, narrow marsh also occurs downstream of the Tunnel crossing, within moderate productivity (yellow-coded) habitat on the south bank. Riprap armours intermittent sections of the shoreline.

4.2.1.3 Aquatic Resources

The food web of the lower Fraser River ecosystem is detritus-based, with much of the production derived by bacteria living on detrital organic material (Levings 2004). Sources of carbon in the food web include material from shoreline and riparian vegetation, as well as from benthic algae growing on the substrate (Kistritz et al. 1983, Levings 2004). Detritus is used by invertebrates such as chironomids, harpacticoid copepods, and amphipods for secondary production in the estuary, which are in turn consumed by fish (Levings 2004).

The lower Fraser River supports 42 species of fish, six of which are introduced from outside the Fraser River basin (Richardson et al. 2000). Of the native fish species, seven are anadromous and 10 are considered transient within the estuary and lower reaches of the river (Healey 1997). Anadromous species of high CRA importance that rely on aquatic habitats throughout the Fraser River estuary during different stages of their life cycle, include five species of Pacific salmon, i.e., chinook (*Oncorhynchus tshawytscha*), chum (*O. keta*), coho (*O. kisutch*), pink (*O. gorbuscha*), and sockeye (*O. nerka*), as well as coastal cutthroat trout (*O. clarkii*), and steelhead/rainbow trout (*O. mykiss*).

Other fish species that inhabit the lower Fraser River mainstem and its tidal sloughs, backwaters and tributaries include prickly sculpin (*Cottus asper*), peamouth (*Mylocheilus caurinus*), redbreasted shiner (*Richardsonius balteatus*), northern pikeminnow (*Ptychocheilus oregonensis*), starry flounder (*Platichthys stellatus*), lamprey (*Lampetra* sp.), and threespine stickleback (*Gasterosteus aculeatus*) (Richardson et al. 2000).

Introductions of non-native fish species have occurred in the lower Fraser River; however, no major shifts in the species composition, density, and biomass of the native fish community have been recorded (Richardson et al. 2000). Three non-native species that are well-documented to reside in the Lower Fraser River are carp (*Cyprinus carpio*), brown catfish (*Ameiurus nebulosus*), and black crappie (*Poxomis nigromaculatus*).

Life histories, biology and habitat requirements for Pacific salmon, sturgeon, eulachon, trout, and char species of the lower Fraser River are summarized below.

Chinook salmon

Chinook salmon is the largest in size of the Pacific salmon species that return to the Fraser River and its tributaries to spawn (DFO 2011). Spawning locations in the Fraser River watershed are widely distributed over 900 km from the mouth of the Fraser River (DFO 2011). More than 100 spawning sites have been identified in numerous tributaries of the Fraser River (Candy et al. 2002, DFO 2011).

Chinook salmon return to the Fraser River to spawn over an extended period from February to November, as three-, four-, or five-year-old fish (DFO 2011). Generally, stream-type chinook migrate upriver between March and September, while ocean-type chinook migrate between September and November, only a few weeks or even days before spawning (Fraser et al. 1982, Candy et al. 2002, Parken et al. 2008). Spawning occurs from August to December, depending on the stock (Candy et al. 2002).

In their natal streams, chinook spawn from August to December, depending on the stock (Candy et al. 2002). Adult chinook, like other Pacific salmon species, deposit their eggs in gravel and die after spawning. Chinook fry emerge in March through June (Fraser et al. 1982). After emergence from gravel in locations well upstream of the lower Fraser River's sand reach, stream-type juvenile chinook rear in freshwater for one or more years (Healey 1983, 1991) and migrate to sea as smolts between January and July (Healey 1991, Boehlert 1997). Ocean-type chinook migrate to sea during their first year of life between April and October, after spending only two to five months in fresh water (Healey 1983, 1991). On average, estuarine residence time of juvenile chinook likely ranges between one week to one month (Quinn 2005, Northcote

et al. 2007). Stream-type chinook generally do not occupy tidal channels; however, ocean-type chinook are found rearing in the tidal marshes of the Woodward Island complex and Ladner Marsh of the inner Fraser River estuary (Levy and Northcote 1982, Northcote et al. 2007). Their abundance peaks in May and June (Northcote et al. 2007). As they grow, chinook juveniles enter the ocean and begin their offshore migration. The diet of younger juvenile chinook in the inner estuary consists of epibenthic prey (harpacticoid and cyclopoid copepods) associated with the detrital food web (Northcote et al. 2007). Contribution of terrestrial insects and fish to the diet of juvenile chinook increases as they grow (Northcote et al. 2007).

Fraser River chinook are subject to numerous fisheries (DFO 2011). Lower Fraser River ocean-type chinook are commonly caught off the west coast of Vancouver Island, while the South Thompson ocean-type chinook are commonly caught in Alaska, northern, and central B.C. (Tucker et al. 2011). Fraser River chinook salmon stocks are not federally or provincially listed; however, they have experienced depressed production in recent years (DFO 2011). The lower Fraser River chinook stock is numerically dominated by autumn-returning, ocean-type fish originating from the Harrison River (DFO 2011). Over the last decade, Fraser River stream-type chinook escapements declined steeply between 2003 and 2009, with smolts that entered the ocean in 2005 and 2007 having fared particularly poorly (Pacific Salmon Commission 2013). Recent escapements indicate that the declining trend in stream-type chinook may have halted. The rebuilding process has been particularly slow, however, with fish exhibiting early maturation, smaller body size, and lower fecundity (Pacific Salmon Commission 2013). In contrast, escapements for ocean-type chinook have been increasing or showing no discernible trends (Pacific Salmon Commission 2013).

Limiting factors for chinook populations include fisheries-induced and natural (e.g., due to predation) mortality, climatic variability, habitat degradation, or combination. Fraser River chinook are subject to numerous coastal and offshore fisheries. Coastal catches are dominated by ocean-type fish, and fishing mortality exerts some pressure to ocean-type stocks (DFO 2011). Coastal fisheries to some extent, as well as offshore fisheries likely limit the recovery of stream-type chinook (Tucker et al. 2011). Other limiting factors include variability in climatic and oceanographic conditions. Shifts in ocean conditions influence prey availability and abundance, which in turn affect chinook growth rates, year class strength, and survival (Beamish and Mahnken 2001, Trudel et al. 2007, MacFarlane 2010, Duffy and Beauchamp 2011, Tucker et al. 2012). For example, good feeding conditions for rearing chinook that enter the marine environment may result in early rapid growth, which is thought to increase likelihood of survival (Percy 1992, Trudel et al. 2007). Natural mortality due to predation may also limit chinook recovery. For example, chinook salmon account for more than 80 per cent of the diet of

southern resident killer whales (*Orcinus orca*) from May to September, when southern resident killer whales are in their summer critical habitat (Hilborn et al. 2012a). Habitat degradation as a result of urbanization, resource extraction activities, and agricultural land use has also contributed to chinook population declines (DFO 1999).

Chum salmon

Chum salmon have the widest geographic distribution of all Pacific salmon, ranging in North America from Monterey, California to the Arctic coast (Salo 1991). Historically in the North Pacific Ocean, they may have constituted up to 50 per cent of the annual biomass of all Pacific salmon combined (Salo 1991). Chum salmon spawn in streams of various sizes, including the lower Fraser River mainstem between Chilliwack and Hope (Ryall et al. 1999).

Chum salmon are the last of the Pacific salmon to return to their natal streams. Returning chum salmon can be divided into early (summer) and late (fall) run stocks (Salo 1991). In the Fraser River, chum are fall run stocks that migrate upstream to spawn from September to December, with peak spawning migration occurring in October (Grant and Pestal 2009). The runs consist of three-, four-, and five-year-old chum, with four-year-olds dominating (Beacham and Starr 1982, Pauley et al. 1988, Salo 1991).

The majority of spawning locations for chum in the Fraser River watershed are located in tributaries of the lower Fraser River downstream of Hell's Gate, near Hope, as chum are reputed to be poor or unwilling leapers (Salo 1991). Chum rarely ascend fish ladders or other significant obstacles, and only few spawning locations occur in tributaries in the Fraser River canyon (Ryall et al. 1999, Holtby and Ciruna 2008). Most (>90 per cent) of the Fraser River chum production comes from about 10 tributary streams in the lower Fraser River that have natural spawning populations and, in some cases, major hatchery production facilities (Ryall et al. 1999, Holtby and Ciruna 2008). These include the Harrison, Chehalis, Chilliwack, and Stave rivers (Ryall et al. 1999, Holtby and Ciruna 2008).

Once chum salmon arrive at the mouth of their natal stream, they may spend several days milling before ascending. In Skagit Bay, located in Puget Sound, Washington, chum salmon have been reported to mill for about three weeks (Eames et al. 1981). The milling period becomes shorter as the spawning season progresses. Returning adult chum salmon stop feeding just before entering fresh water (Pauley et al. 1988).

After emergence, chum fry promptly migrate downstream to the estuary where they linger until they transition to higher salinity waters (Salo 1991). Outmigration occurs from February to June, and peaks between mid-March and the end of April (Beacham and Starr 1982, Salo 1991).

In the estuary and lower reaches of the Fraser River, chum fry prey mainly on harpacticoid copepods (Mason 1974, D'Amours 1987, Webb 1991, Levings et al. 1995). Other prey include gammarid amphipods, chironomid larvae and pupae, and adult insects (Mason 1974, Dunford 1975, Levings et al. 1995). In the estuary, residence time for chum fry has been recorded to range from 11 days to a few weeks (Healey 1982, Levy and Northcote 1982). Movement into the deeper waters of the Strait of Georgia occurs in June, and movement out of the Strait of Georgia occurs soon after, in July (Healey 1980). Migration of chum fry to salt water is obligatory within the first summer after hatching, as chum salmon juveniles lose their ability to tolerate brackish salinities (Pauley et al. 1988). At sea, immature chum salmon become widely distributed throughout the north Pacific Ocean (Pauley et al. 1988).

Chum salmon are harvested in CRA fisheries throughout B.C. (DFO 2012). Catches of inshore chum stocks have been fluctuating since the early 1950s (Ryall et al. 1999). Since the implementation of fisheries management tools in the 1980s, the Fraser River chum stock has exhibited moderate growth (Ryall et al. 1999, Pacific Salmon Commission 2014), with total escapement estimates consistently above the escapement goal from 1990 to the mid-2000s (Hilborn et al. 2012b). Although escapement levels declined from the mid-2000s, the trend appears to be reversing since 2011 (Pacific Salmon Commission 2014). In 2013, the Marine Stewardship Council certified the Fraser River commercial chum fishery as sustainable and well-managed (Marine Stewardship Council 2013).

Coho Salmon

In North America, coho salmon are distributed from Kotzebue Sound in northwest Alaska, to Monterey Bay in California (Sandercock 1991). In B.C., they can be found in nearly every accessible coastal stream. They also migrate some distance inland in large rivers and spawn in smaller tributaries of the Skeena, Bella Coola, Nass, and Taku rivers, and in the middle tributaries of the Fraser River. Coho is the most widespread of the Pacific salmon in B.C., with no one area being the dominant producer (Sandercock 1991).

Coho have the least variable life history of the Pacific salmon species. Adult coho typically return to spawn in the fall and early winter, and discrete seasonal runs do not generally exist (Holtby and Ciruna 2008). They migrate actively during daylight hours, with diel vertical migration also influenced by water turbidity, degree of sexual maturity, and run size (Sandercock 1991).

The eggs incubate during winter in the gravels of suitable spawning streams, with incubation timing generally ranging from six to eight weeks (Sandercock 1991). From mid-March to late June, free-swimming fry emerge and take up residency in the stream for a year or more (Fraser et al. 1982, Sandercock 1991). When they are about to transition physiologically into smolts, they begin moving downstream in aggregations of 10 to 50 fish. Outmigration generally occurs from mid-April to mid-June, with a peak observed in mid-May (Fraser et al. 1982). In the estuary, growth is rapid (Sandercock 1991). Similar to chinook, coho smolts remain in the estuary and lower reaches of the Fraser River for a few weeks while physiologically adapting to higher salinity conditions (Fraser et al. 1982).

Coho salmon are not federally or provincially listed; however, the Interior Fraser populations were designated as Endangered by COSEWIC (COSEWIC 2002). The status of the Interior Fraser Coho Salmon is anticipated to be re-assessed by COSEWIC and an updated status report is expected to be produced in 2015 (Decker and Irvine 2013). Coho are taken in net, as well as hook and line CRA fisheries; however, catches in south coastal B.C. have declined from 1.55 million fish in the mid-1980s, to virtually zero in the late 1990s, and have remained low since then (DFO 2002). This decline was largely attributed to overharvesting, and was followed by implementation of conservation measures, such as limiting the exploitation rate to three per cent or less, time and area fisheries closures, as well as non-retention (DFO 2012).

Pink Salmon

In North America, pink salmon is distributed from the Sacramento River, California, to the Beaufort Sea, east of Point Barrow, northwestern Alaska. In B.C., pink salmon distribution ranges from the Taku River on the north B.C. coast to the Fraser River (Heard 1991). Pink salmon have a fixed two-year life cycle resulting in 'even-year' and 'odd-year' brood lines that are reproductively isolated. In Puget Sound, the southeastern Vancouver Island, and the Fraser River, 'even-year' pink are either absent or quite rare (Holtby and Ciruna 2008).

Pink salmon have the shortest life cycle of all Pacific salmon since they always mature as two-year-old fish (Labelle 2009). In the Fraser River, pink salmon return in odd years (Labelle 2009). Return migration typically peaks from late July to early September (Heard 1991). Spawning occurs mostly in September and October, and is typically concentrated in the Fraser River tributaries below Hope, with significant spawning also occurring in the Thompson River (Labelle 2009). The eggs incubate in the gravel for five to eight months (Heard 1991). From mid-April to mid-May, free-swimming fry emerge at night and migrate quickly downstream using sections of the river mainstem characterized by fast-flowing water (Heard 1991). In the estuary, pink fry migrate quickly through the marshes of the lower Fraser River and rear in nearshore areas of the estuary and adjacent coastal waters of the Strait of Georgia (Godin 1981, Levy and Northcote 1982).

Pink salmon are not federally or provincially listed (B.C. CDC 2015). They are the most abundant salmon species in B.C. and the Fraser River is a major contributor to total pink salmon production. Fisheries catches increased from the 1950s to the late 1980s, when they exceeded 20 million fish, but subsequently declined in the 1990s (Labelle 2009). Since 1999, exploitation rates on Fraser River pink salmon have decreased substantially, averaging only eight per cent of the total return (Labelle 2009). Fisheries targeting Fraser River pink salmon are limited due to conservation constraints for stocks of concern of other salmonid species, such as the Cultus Lake sockeye, the Interior Fraser coho, and the Interior Fraser steelhead (Labelle 2009).

Sockeye Salmon

In North America, spawning populations of sockeye salmon have been reported from the Sacramento River, California, to the Chukchi Sea, northwestern Alaska (Burgner 1991). Sockeye salmon are found throughout B.C., especially in large river systems with an abundance of large nursery lakes, such as the Skeena and Fraser River systems (Burgner 1991, Holtby and Ciruna 2008). The Fraser River system contains 50 to 60 sockeye salmon stocks that spawn in tributaries of about 22 nursery lakes (Groot and Cooke 1987).

Sockeye salmon has three distinct life history types (Burgner 1991). Kokanee are not anadromous and spend their entire life in fresh water (Burgner 1991). Lake-type sockeye spawn in streams and rear for a year or more in freshwater nursery lakes. River-type sockeye spawn in streams, but rear in flowing water and may transition into smolts soon after emergence. Sea-type sockeye is a special variety of river-type sockeye that rear in the river for several months after emergence from the gravel and enter the ocean in their first year of life (Wood et al. 2008). Lake- and river-type sockeye are found throughout B.C., although river-type predominate northern glacial rivers, whereas lake-type predominate large river systems, such as the Fraser, Skeena, and Nass (Holtby and Ciruna 2008). In the Fraser River, the largest population of sea-type sockeye occurs in the Harrison River (Beamish et al. 2010).

Sockeye salmon are commercially the most valuable of Pacific salmon in the North Pacific region, comprising about 50 per cent of the Fraser River salmon fishery (Birtwell et al. 1987*b*). Fraser River sockeye salmon typically return as four-year-old adults and populations have characteristic timings of return, broadly classified into four groups or runs (Gable and Cox-Rogers 1993). The early Stuart run consists of populations that spawn in tributaries to Stuart, Takla, and Trembleur lakes of the upper Fraser River watershed (Gable and Cox-Rogers 1993). The three remaining runs, early summer, summer, and late, are not geographically discrete, and each contains populations from throughout the Fraser River drainage (Gable and Cox-Rogers 1993).

The peak arrival for early Stuart sockeye typically occurs in early July, followed by the early summer run in late July, the summer run in early August, and the late run about the third week of August (Gable and Cox-Rogers 1993). Late-run stocks may hold in the Fraser River estuary for several weeks before migrating upriver. Consequently, their spawning migration may peak in late September (Gable and Cox-Rogers 1993). At spawning grounds, eggs incubate during winter, and in spring free-swimming fry emerge that take up residency in a downstream nursery lake (Burgner 1991). After rearing for a year, sockeye smolts (age 1+) migrate downstream in fast flowing, mid-channel areas of the river and leave the estuary rapidly (Birtwell et al. 1987*b*). Smolt outmigration from nursery lakes generally occurs from mid-April to late-May (DFO 2014*a*). One notable exception is the Harrison sockeye that have a unique age structure and life history compared to all other stocks. Harrison sockeye fry migrate to the estuary shortly after gravel emergence and rear in sloughs of the inner Fraser River estuary, including Deas Slough, before entering the Strait of Georgia (Dunford 1975, Levy and Northcote 1981, 1982, Birtwell et al. 1987*b*). In Deas Slough, sockeye underyearlings have been caught from April to October, with peak abundance from late June to early July (Birtwell et al. 1987*b*). Upon entering the Strait of Georgia, sockeye smolts migrate primarily through the Johnstone and Queen Charlotte straits towards the North Pacific Ocean (Groot and Cooke 1987).

Sockeye salmon spawn in a variety of habitats, including headwater streams, small tributaries, river outlets, and lake beaches. Spawning occurs from early August to late November, with average spawning dates exhibiting considerable variability within regions (Linley 1993). Free-swimming fry emerge in spring and rear in freshwater habitats (Burgner 1991). After about a year or more, sockeye smolts (age 1+) migrate downstream in fast flowing, mid-channel areas of the river, and leave the estuary rapidly (Birtwell et al. 1987*b*). Smolt out-migration generally occurs from early April to the end of May (Beamish et al. 2010). One notable exception is the Harrison sockeye that have a unique age structure and life history compared to all other stocks. Sea-type Harrison sockeye fry migrate to the estuary shortly after gravel emergence and rear in Fraser River estuary habitats, including Deas Slough and Ladner Reach, before entering the Strait of Georgia (Dunford 1975, Levy and Northcote 1981, 1982, Birtwell et al. 1987*b*). In Deas Slough, sockeye underyearlings have been caught from April to October, with peak abundance from late June to early July (Birtwell et al. 1987*b*).

Residence time in the Strait of Georgia ranges from 45 to 59 days, with a mean of 54 days (Preikshot et al. 2012). Upon entering the Strait of Georgia, sockeye smolts disperse either as a result of innate behaviour, physical forcing in the marine environment, or both. Relatively large abundances of juvenile sockeye salmon migrate into the waters of the Gulf Islands (Preikshot et al. 2012). During rearing in the marine environment, juvenile sockeye diet is dominated by

amphipods, followed by tunicates and calanoid copepods (Beamish et al. 2010, Preikshot et al. 2010). Typically, sockeye juveniles migrate to the North Pacific Ocean in June or July through the Johnstone Strait (Preikshot et al. 2012). However, some Harrison sockeye may migrate later in the calendar year from October to December through the Juan de Fuca Strait (Beamish et al. 2010).

Sockeye salmon are not federally or provincially listed; however, the Cultus Lake population was designated as Endangered by COSEWIC in 2003 (COSEWIC 2003a). On average, sockeye is the most important of the Pacific salmon species in terms of commercial landed value, followed by chinook and chum (DFO 2012). Sockeye salmon is also caught in sport fisheries and in Aboriginal active food driftnet (i.e., gillnet) fisheries on the Lower Fraser River.

Most Fraser River sockeye stocks are recovering from collapse in the early 1900s as a result of river blockages and overfishing (Cass et al. 2000). Since the mid-1980s, efforts undertaken for rebuilding of the stocks have included setting of escapement targets, which were informed by results from historical catch reviews, stock-recruitment analyses, and spawning and lake rearing habitat capacity estimates. To increase escapement, average exploitation rates were also reduced (Cass et al. 2000). Sockeye spawning escapement to the Fraser River gradually increased from an average of 1.5 million fish per year in the 1950s to 10.7 million fish per year in the 1990s (Cass et al. 2000). Increases in escapement have mainly occurred in the large actively managed stocks and cycle lines (e.g., Early Stuart, Late Stuart, Quesnel and Late Shuswap), whereas escapements to less actively managed stocks (e.g., Cultus) have been highly variable since the 1950s (Cass et al. 2000). Recently, escapement variability has been particularly large, with the 2009 return (1.6 million) and 2010 return (28.3 million) among the lowest and highest, respectively, on record since 1952 (DFO 2014b).

White Sturgeon

White sturgeon are known to occur in the mainstems of large river systems of the Pacific coast of North America, such as the Fraser, Columbia, and Sacramento rivers. In the Fraser River, they are distributed from the river mouth upstream past the Morkill River, northwest of McBride. They also occur in the lower reaches of large tributaries, such as the Harrison, Nechako, and Stuart rivers, and in large lakes, such as Fraser, Takla, Trembleur, Stuart, Williams, and Harrison lakes (COSEWIC 2003b).

White sturgeon in the lower Fraser River are considered anadromous, with limited migration into marine waters and juvenile rearing in the estuary (COSEWIC 2003*b*). They are long-lived (>100 years), with delayed sexual maturity, and high first-year mortality (Hatfield et al. 2004). Spawning occurs in the meandering reach of the lower Fraser River from the confluence of the Sumas River upstream to the Coquihalla River; there is no evidence of spawning in the tidally influenced river mainstem (Levings and Nelson 2003). Spawning occurs during peak freshet (from May to July; COSEWIC 2003*b*, Hatfield et al. 2004) in side-channels and large tributary river fans, in low-velocity near-bed flows, over gravel, cobble, and sand (Levings and Nelson 2003, Perrin et al. 2003).

After hatching, larvae remain near the riverbed in close proximity to spawning habitat, where they feed on zooplankton and dipteran chironomids (Perrin et al. 2003). Juvenile white sturgeon disperse more readily into feeding, and overwintering habitats (Fraser River White Sturgeon Working Group 2005). They rear in the lower reaches of tributaries, large backwaters, side-channels, and sloughs throughout the lower Fraser River (Glova et al. 2008). Higher catches of juvenile white sturgeon have been reported from the Annacis Channel and Hatzic Slough, and to some extent from the Port Mann Bridge, Stave and Matsqui areas (Glova et al. 2008). Near the study area, white sturgeon have been reported from the BC Ferries Fraser Shipyards in the South Arm, the main river channel off Deas Island, immediately upstream of the Tunnel crossing, and upper Deas Slough (Levings and Nelson 2003, Glova et al. 2008). Juveniles rear in a wide range of water depths (1.3 to 6.0 m), but more commonly are found in slow-flowing areas less than five metres deep with fine substrates in side channels, side pools, backwaters and nearshore mainstem open channels (Glova et al. 2008).

Although adult white sturgeon may briefly move into shallower areas to feed during spring and summer, they are typically found in deep nearshore areas, adjacent to heavy flows, defined by deposits of sand and fine gravel with backwater and eddy flow characteristics (COSEWIC 2003*b*). Important spring and summer feeding areas include the Matsqui Channel and Hatzic Eddy upstream of Mission, as well as the mouth of the Pitt River, and the waters at the Port Mann Bridge, Barnston, Douglas, and Annacis islands (Glova et al. 2010). Adult white sturgeon are mainly piscivorous, and feed primarily on eulachon, salmon, and cyprinids (Lane and Rosenau 1995). As water temperatures decrease in the fall and winter, white sturgeon migrate to overwintering areas where they likely become sedentary and congregate in densely spaced groups (Neufeld et al. 2010, Ghilarducci and Reeve 2012). Overwintering habitats include areas of deeper, slow-moving water, widely scattered from Deas Island to the Sumas River confluence (Neufeld et al. 2010, Ghilarducci and Reeve 2012).

The lower Fraser River population of white sturgeon was down-listed to Threatened by COSEWIC in 2012 from the 2003 designation of Endangered (COSEWIC 2003b). It is provincially Red-listed (B.C. CDC 2015). White sturgeon in the lower Fraser River underwent historic fishery removals in the early 1900s, which significantly reduced the population (Walters et al. 2005). However, the population appears to be recovering as a result of ongoing fisheries management (Walters et al. 2005). A commercial fishery in the lower Fraser River no longer exists (Fraser River White Sturgeon Working Group 2009). Since 1994, commercial gill net fisheries are not permitted to take sturgeon, and First Nations are discouraged from taking sturgeon unless the fish died in their nets. Also since 1994, sturgeon caught recreationally in the tidal and non-tidal waters of the lower Fraser River must be released (Fraser River White Sturgeon Working Group 2009).

Green Sturgeon

Green sturgeon (*A. medirostris*) in B.C. span the entire coast (Scott and Crossman 1973). The extent of freshwater habitat use is unknown (COSEWIC 2004). Since 1985, there have been about 15 to 20 reports of green sturgeon in the lower Fraser River, from the river mouth to 90 km upstream. There is no evidence that spawning has ever occurred in Canadian rivers (COSEWIC 2004). Green sturgeon are long-lived, slow-growing, and reach sexual maturity at an advanced age (Houston 1988). They spend their first one to four years in freshwater, and gradually adjust to estuarine conditions as they grow older. They enter the marine environment as sub-adults but maintain estuarine holding areas (COSEWIC 2004). When in the marine environment, green sturgeon are thought to undergo a northern migration. Green sturgeon in B.C. are thought to originate from spawning populations in the U.S. (COSEWIC 2004). Green sturgeon have been caught incidentally in large bottom-trawl hauls in the Strait of Georgia, and in salmon gill nets at the mouth of the Fraser River (COSEWIC 2004). Habitat requirements in brackish environments are thought to resemble those of white sturgeon (COSEWIC 2004).

COSEWIC re-assessed the status of green sturgeon in 2013 and maintained its designation as species of Special Concern (COSEWIC 2014). The species is listed as Special Concern under Schedule 1 of the *Species at Risk Act (SARA)* (Government of Canada 2006), and is provincially Red-listed (B.C. CDC 2015). A comprehensive population size and trends analysis has not been done for the green sturgeon population in Canada. However, catch information, which is largely anecdotal prior to 1996, may indicate that the green sturgeon population has suffered a decline over the past few decades (COSEWIC 2014).

Eulachon

A small, schooling, anadromous fish species, eulachon return to the lower Fraser River to spawn when they are three to four years of age (Cambria Gordon Ltd. 2006). Spawning migration spans from mid-March to mid-May (Hay and McCarter 2000, LGL and Terra Remote Sensing 2009). Spawning occurs in the river mainstem and occasionally in large tributaries, from Deas Island to Mission, but spawning locations vary among years (Hay and McCarter 2000, Hay et al. 2002). Due to inter-annual variation in spawning locations, the entire lower Fraser River is considered to contain suitable spawning habitat for eulachon (B. Ennevor, Fisheries Resource Manager, DFO, personal communication, January 6, 2014).

Preferred spawning habitat is located in areas of relatively slow current (<0.7 m/s), on plateaus or edges composed of stable fine-medium and coarse sand, pebbles, and gravel, in depths of less than seven metres (LGL and Terra Remote Sensing 2009). To reach spawning habitat, eulachon transit through areas of relatively slow current that are five to 12 m deep and with stable sandy substrates (LGL and Terra Remote Sensing 2009). Immediately after hatching, larvae are rapidly flushed to sea, where they remain in low-salinity surface waters of the Fraser River estuary and rear for several weeks or longer (Hay and McCarter 2000). Juvenile, sub-adult, and adult eulachon exhibit schooling behaviour and live near the ocean bottom at depths of 20 to 150 m (Hay and McCarter 2000). When eulachon reach maturity, and prior to entering the river, they hold in brackish water while making physiological changes that allow them to survive in fresh water.

Eulachon (Central Pacific Coast and Fraser River populations) were designated in 2011 by COSEWIC as Endangered (COSEWIC 2011), and are provincially Blue-listed (B.C. CDC 2015). The Fraser River and Central Pacific Coast populations of eulachon are currently being considered for listing as Endangered under SARA (DFO 2014c). Although historically very abundant, eulachon returning to the lower Fraser River began declining steadily in the mid-1940s, and exhibited a steeper decline in the 2000s (Moody 2008, Schweigert et al. 2012). Commercial and recreational harvesting of eulachon in the Fraser River have been suspended since the early 2000s, and only a very small Aboriginal ceremonial fishery continues today (Schweigert et al. 2012).

Coastal Cutthroat Trout

Coastal cutthroat trout are found in a wide range of habitats. In B.C., they inhabit low-elevation lakes and rivers along much of the coast, including streams in the Fraser River basin. Inland penetration is generally less than 150 km (Costello 2008). Their relatively small size at maturity allows them to use smaller streams than other salmonids (Slaney and Roberts 2005).

The Fraser River, including its tributary streams, supports all cutthroat life history forms. These include resident forms in headwater streams that exhibit little instream movement, river-run forms that move between small spawning-rearing tributaries and large river mainstem foraging areas, lake-run forms that migrate between lakes and foraging/spawning areas instream, and anadromous (sea-run) forms that migrate to the estuary or the ocean for less than a year before returning to fresh water to spawn (Slaney and Roberts 2005). Sloughs and backwaters along the lower Fraser River mainstem provide rearing, overwintering, and migratory habitat for anadromous, river-run, and (potentially) lake-run cutthroat trout.

Unlike Pacific salmon, but consistent with other trout and char, coastal cutthroat trout are able to spawn multiple times in successive years. Spawning usually occurs from late winter to spring (McPhail 2007), though sea-run populations have also been known to spawn during the fall (McPhail 2007). Spawning typically occurs in small, low-gradient streams (Hartman and Gill 1968), in pool tail-outs with gravel substrate ranging from 5 mm to 50 mm (Slaney and Roberts 2005). Newly hatched alevins remain in gravel until fry emerge, usually between March and June (Trotter 1997). Fry initially occupy microhabitats with low flow levels, gradually moving into deeper microhabitats with higher flow and more cover, such as large woody debris, streambank root masses, instream and overhanging vegetation (Solazzi et al. 2000, Slaney and Roberts 2005).

Depending on the life-history form, adults either remain in the natal stream, or migrate to lakes or larger river systems to forage before returning to spawn. Sea-run cutthroat stay in freshwater systems for one to five years before migrating to the ocean (Trotter 1997, Slaney and Roberts 2005), between the months of March to June (Slaney and Roberts 2005). While at sea, coastal cutthroat trout remain close to shore before returning to fresh water in the spring (Trotter 1989). Generation time for coastal cutthroat trout is three to five years (Peterson and Fausch 2008).

Coastal cutthroat trout are primarily carnivores, though their diet varies by life form and life history stage. Fry feed on small prey, particularly chironomid larvae (Glova 1984). Resident form adults feed primarily on insects, whereas lacustrine form adults tend to feed on a wider variety of prey, including zooplankton and small fish (McPhail 2007). In the ocean, sea-run cutthroat feed on small fish, and invertebrates including amphipods, isopods, decapods, and euphausiids (Trotter 1989, Brodeur and Pearcy 1990).

Coastal cutthroat trout (ssp. *clarkii*) are provincially Blue-listed (B.C. CDC 2015). Population sizes of coastal cutthroat trout are typically in the order of tens to hundreds of individuals, even in the largest systems. As a result, cutthroat populations are susceptible to disturbance (e.g., logging, resource extraction, urban development, stream channelization), particularly

when it leads to impairment of habitat quality (Costello 2008). Historically, coastal cutthroat trout have supported diverse and regionally important sport fisheries throughout the Fraser River basin. Although increasingly restrictive fishing regulations have come into effect, angling pressure has likely been another significant factor limiting natural coastal cutthroat production, particularly near urban areas (Post et al. 2002).

Rainbow/Steelhead Trout

Rainbow trout occur in two life history forms, based primarily on where they spend their time feeding and maturing. Stream resident rainbow trout reside entirely in fresh water. Fish of the second form, known as steelhead, are anadromous. Steelhead leave fresh water as juveniles and migrate into the ocean where they grow to maturity before migrating back to their natal spawning grounds (Barnhart 1986). Larger streams with steep gradients emptying directly into the ocean usually support steelhead trout, as do larger rivers, such as the Fraser River (Hartman and Gill 1968). Spawning occurs in spring (February through June) over shallow gravel riffles of a river mainstem or a suitable clear water stream (Barnhart 1986). Hatching occurs approximately within three to four weeks. By mid-summer, fry emerge from the gravel and rear in fresh water for two to five years before smolting and migrating to the ocean (Barnhart 1986). Newly emerged fry rear in shallow depths and over small gravel substrates, and move into deeper and faster-flowing habitats as they grow (Roberge et al. 2002). Yearlings and larger juveniles are associated with large substrates and relatively deep and fast-flowing waters (Rempel et al. 2012). Juvenile steelhead smolts migrate to salt water between late April and mid-June, where they feed and grow rapidly (Levy and Parkinson 2014). Upon maturity, steelhead return to their natal streams to spawn, and spawning occurs more than once (Levy and Parkinson 2014). Spent spawners migrate to the ocean to feed and may return to their spawning grounds within the same year, or skip a year before spawning again (Levy and Parkinson 2014).

Rainbow/steelhead trout are not provincially or federally listed. However, wild steelhead stocks in the lower Fraser River have declined to 30 per cent of estimated carrying capacity since the early 1990s, largely due to reduced ocean survival and impaired freshwater habitat quality (Lill 2002). Fisheries restrictions and area closures have led to a reduction of angling pressure. Fishing tends to be restricted to recreational fisheries, as well as limited and localized Aboriginal harvesting (Beacham et al. 2004). Steelhead are also incidentally caught in salmon fisheries (Beacham et al. 2004). In the early 2000s, the Greater Georgia Basin Steelhead Recovery Action Plan was initiated with the primary objective to stabilize and restore wild steelhead stocks and habitats within the lower Fraser River (Lill 2002). Initiatives within the action plan include habitat protection and restoration, stream enrichment, as well as research including stock assessment (Lill 2002).

Dolly Varden

Dolly Varden (*Salvelinus malma*) are found in coastal areas of the Pacific Ocean from Washington to southeast Alaska. In B.C., Dolly Varden can be found in most coastal drainages, and are associated with cool-body watersheds (McPhail 2007). Dolly Varden are largely a coastal and anadromous species entering the ocean regularly, with distribution of this species not typically extending far inland (i.e., past Hope, within the Fraser River system) (McPhail 2007). Dolly Varden are commonly smaller than bull trout (*S. confluentus*), inhabiting small streams and feeding primarily on drift. In contrast, bull trout (described below) are typically larger, piscivorous, inhabiting cool waters throughout the interior, and generally absent from shorter coastal rivers (McPhail 2007). Where distributions overlap, Dolly Varden and bull trout coexist, without extensive hybridization (McPhail and Baxter 1996). Within B.C., their geographic ranges overlap in northern and western-central Coast Mountain drainages, and in the lower Fraser Valley (McPhail and Baxter 1996).

Dolly Varden occurs in three life-history forms: an anadromous form that migrates between freshwater streams and the ocean, a stream-resident form that remains in rivers and streams for most of its life, and a lake-run form that remains within a single freshwater body and spawns in adjacent streams (McPhail 2007).

Spawning occurs in autumn within headwaters of small streams. Females lay between 70 and 500 eggs, in pool tail-outs (McPhail 2007). Fry emerge from the gravel in spring (April/May), with juveniles remaining in the stream for two to four years (Armstrong 1970). Juveniles use a variety of habitats, including areas of still or moving water, with gravel or muddy substrates having dense instream vegetation, or open water with little or no instream complexity (Armstrong and Morrow 1980). Large rivers are important as overwintering habitats for larger juveniles, as well as sub-adult anadromous Dolly Varden. The lower Fraser River is likely used as a migratory corridor by Dolly Varden, due to its proximity to nearshore estuarine and coastal feeding and overwintering grounds.

Dolly Varden smolts migrate to the ocean in spring and may remain for only two to four months before returning to fresh water (Armstrong and Morrow 1980), where they feed on the eggs and flesh of decaying salmon (Bond and Quinn 2013). Alternatively, Dolly Varden may remain in marine waters well into the fall months, returning only for spawning or overwintering in freshwater habitats (Bond and Quinn 2013). Spawning can occur over multiple years, but does not necessarily occur in successive years (Mochnacz et al. 2010). Dolly Varden movement patterns are complex and often influenced by a combination of age, size, or maturational state, and the relative abundance of resources in marine and fresh waters. Local environmental

conditions influence the relative benefit of each habitat, and Dolly Varden may respond with flexibility in the timing of movements among habitats (Bond and Quinn 2013). Generation time for Dolly Varden is five years (Scott and Crossman 1973).

The diet of Dolly Varden varies with life history stages, and is also apparently influenced by the presence of competing fish species. The stream-resident form tends to feed near the bottom of creeks on nymphs and larvae of aquatic insects, with diet shifting to larger prey as fish grow (McPhail 2007). The lake-run form feeds on zooplankton, shifting to benthos found on the lake floor when trout are present (McPhail 2007). Sea-run Dolly Varden feed on macroinvertebrates, juvenile salmon, and other species of fish (Armstrong 1965).

Dolly Varden are not provincially or federally listed. Although population sizes within the Fraser River basin are largely unknown, Dolly Varden are thought to be susceptible to disturbance (e.g., logging, resource extraction, urban development, stream channelization), particularly when it degrades habitat quality and reduces availability of suitable spawning and rearing habitat (COSEWIC 2010). Dolly Varden have and continue to support diverse and regionally important sport fisheries throughout the Fraser River basin.

Bull Trout

Bull trout are endemic to western Canada and the U.S. Pacific Northwest. The species' current distribution extends from the Oregon-California border and northern Nevada, north to southern Yukon, and southwestern Northwest Territories (McPhail 2007). Although bull trout reach the Pacific coast (B.C. Fraser and Squamish River drainages; Washington: Skagit River drainage, Olympic Peninsula), they are generally restricted to interior drainages (COSEWIC 2012). In B.C., bull trout are found in the cool waters of most major interior watersheds (i.e., upper Columbia, Peace, Liard, and Yukon River drainages), and in major coastal watersheds that penetrate into the interior (Fraser, Homathko, Klinaklini, Skeena, Nass, Iskut-Stikine, and Taku River drainages) (McPhail 2007).

Of the salmonids present within the Fraser River watershed, bull trout are notably a cold water species generally found in waters below 18°C and most commonly in temperatures less than 12°C (Dunham et al. 2003). They exhibit variable life histories (McPhail and Baxter 1996, McPhail 2007), including stream resident, adfluvial (lake-run), large river (fluvial), and sea-run.

Stream resident bull trout are typically associated with high gradient, headwater streams in mountainous regions. They are usually separated from other populations by barrier (e.g., falls, velocity barriers, high temperature) (McPhail and Baxter 1996, McPhail 2007). Stream resident bull trout are non-migratory, and spend their entire life in small streams (McPhail and Baxter 1996, McPhail 2007).

Adfluvial bull trout migrate between lakes or reservoirs and tributary rivers or streams where they spawn. Spawning can also occur in the inlet or outlet of lakes (Carl et al. 1989). In lakes, adults forage in the littoral zone in the fall and spring, and move to deeper water in the summer, most likely due to temperature constraints (McPhail and Baxter 1996).

Fluvial bull trout live in large rivers and major tributaries, and often migrate to smaller rivers or streams to spawn. Adult bull trout tend to concentrate in cooler areas of the river mainstem, and are often associated with the mouths of spawning streams (McPhail and Baxter 1996, McPhail 2007). Some fluvial bull trout populations are anadromous, and spend part of their life at sea.

Anadromous bull trout populations are suspected to occur in the Squamish and lower Fraser rivers (McPhail and Baxter 1996, McPhail 2007). Because anadromous char populations occur where bull trout and Dolly Varden overlap, evidence that these char are bull trout rather than Dolly Varden is often circumstantial. One char tagged in the Squamish River was recaptured in the Skagit River, after a journey of about 150 km through the Strait of Georgia. Also, tagged char in the Pitt River above Pitt Lake have been recaptured in the Fraser River estuary (McPhail and Baxter 1996).

Bull trout spawn in shallow stream habitats characterized by relatively low gradient, a predominance of small gravel (<20 mm), relatively low water velocity (0.03-0.80 m/s), and proximity to cover (e.g., cut banks, log jams, pools, overhanging vegetation) (McPhail and Baxter 1996). Spawning occurs in the fall, when water temperatures drop below 9°C, which is likely the cue to initiate redd building and spawning behaviour (McPhail and Baxter 1996). Egg incubation occurs during the winter, and fry emerge from the gravel in early spring (mid-April to mid-May) (McPhail and Baxter 1996). Bull trout fry are closely associated with shallow edges of rivers and streams, especially in areas of large, loose gravel, where they use the interstitial habitat for cover (McPhail and Baxter 1996).

Juvenile bull trout rear in spawning streams for at least two years before migrating to the larger rivers, or the ocean, depending on the form (Pratt 1992, McPhail and Baxter 1996). In fresh water, juvenile bull trout tend to shift to deeper, slower-flowing water in the fall, where they stay in contact with coarse substrates and remain closer to cover, which provides ice-free refuge throughout winter (COSEWIC 2012). They forage near the substrate and in the water column, but not at the surface (McPhail and Baxter 1996). As they grow, juveniles shift their diet from benthic organisms and drift to small fish, such as sculpins, mountain whitefish, and trout fry (Pratt 1992).

Migratory forms seek suitable feeding and overwintering habitat in larger streams and rivers, as well as nearshore coastal areas (COSEWIC 2012). After spawning, bull trout move to overwintering habitats by September or October (Hayes et al. 2011, COSEWIC 2012). The lower Fraser River is likely used as a migratory corridor by bull trout, due to its proximity to nearshore estuarine and coastal feeding and overwintering grounds. Generation time for bull trout is five to seven years (Rieman and Allendorf 2001).

Bull trout are provincially Blue-listed and were designated by COSEWIC in 2012 as being of Special Concern (B.C. CDC 2015). Bull trout populations found in the south coast region of B.C. are currently being considered for listing as species of Special Concern under SARA (DFO 2014d). In B.C., bull trout populations are thought to be diminishing (Hammond 2004). Limiting factors include habitat fragmentation resulting from development associated with resource extraction and logging activities, as well as degradation of habitat quality such as through obstruction to movement, stream channel instability, sedimentations, lack of cover, or increasing water temperatures (Hammond 2004). Furthermore, increasing angling effort may pose additional pressure to diminishing bull trout populations, as new roads allows access to streams that were previously remote (Hammond 2004).

4.2.1.4 Deas Slough

Hydrology and Hydraulics

Deas Slough is a backwater feature of the lower Fraser River South Arm. The slough was formerly a side arm of the river that was dammed off at its upstream end in 1949 (Birtwell et al. 1987a). It is situated about 15 km upstream from the Fraser River mouth at Sand Heads. It is approximately 2,700 m long, 250 m wide, with an average depth of five metres (Birtwell et al. 1987a). Some deeper sections exist in dredged locations in front of the two marinas situated on, and occupying about one-third of the shore of the slough's south bank (Birtwell et al. 1987a).

In contrast to riverine areas in the South Arm where the riverbed is dominated by sandy substrate, the bottom material in the slough is predominantly silt and clay (Birtwell et al. 1987a). Infrequent and localized dredging takes place to maintain access to small craft harbours and moorage (FREMP 2006). Recent dredging (February 2014) was initiated in lower Deas Slough to re-establish the depth and width of the navigation channel, and to remove materials around the Ferry Road boat ramp that had been affecting recreational boating activity (PMV 2014b). By November 2014, approximately 60,000 m³ of river bottom were removed by cutter suction and disposed of via in-river dispersal (PMV 2015).

Deas Slough is tidally influenced, with salt water intrusion during the winter freshwater low-flow period, resulting in vertical stratification of the water column. Salinities at depth increase progressively as freshwater flows decrease. However, a sill at the mouth of Deas Slough prevents saline penetration in water greater than four metres deep; thus, salinity at depth is not as high (i.e., approximately 10 practical salinity units) as that recorded in the river just outside the slough, which often reaches 26 practical salinity units (Birtwell et al. 1987a). Stratified conditions in the deeper pockets of the slough are also associated with low levels of dissolved oxygen, and reduced oxidation-reduction potential likely due to low photosynthetic activity, and higher pH (ranging from 6.4 to 8.2), also reflecting the influence of salt water (Birtwell et al. 1987a).

With the onset of freshet, increased river flows reduce salt water intrusion, with low salinity levels characterizing slough waters throughout the water column (Birtwell et al. 1987a). Influx of turbid fresh water reduces water clarity of the slough's surface water; however, DO levels are generally high (Birtwell et al. 1987a). With the progression of freshet, oxidation-reduction potential also rises in response to increased photosynthetic activity (Birtwell et al. 1987a).

Physical Fish Habitat

The shoreline along Deas Slough is designated primarily as highly productive (red-coded) habitat (BIEAP - FREMP 2014). The intertidal bench transitions shoreward from a mudflat into a brackish marsh, with varying width from approximately 10 m along the north and south banks to approximately 200 m at the upstream end of the slough near the Delta Deas Rowing Club, and on either side of the Deas Slough Bridge north support pier (BIEAP - FREMP 2014). Marsh vegetation is dominated by hard-stemmed bulrush (*Schoenoplectus acutus*), Arctic rush (*Juncus arcticus*), Lyngbye's sedge (*Carex lyngbyei*), and common cattail (*Typha latifolia*) (BIEAP - FREMP 2014). Riparian vegetation backing the marsh along the north and east banks of Deas Slough consists of reed canary grass (*Phalaris arundinacea*), and shrub species such as hardhack (*Spiraea douglasii*) (BIEAP - FREMP 2014). The riparian zone on the south bank is narrow and confined to the crest and slope of the dike, consisting primarily of mowed grass and clumps of Himalayan blackberry (*Rubus armeniacus*) (BIEAP - FREMP 2014).

Deas Island is a Metro Vancouver regional park and defines the slough's north bank. Most of the areas south of the slough are farmland (grass, crops). Some of the land is below sea level, and is intersected by ditches to facilitate drainage (Birtwell et al. 1987a). Within the park, as well as immediately upstream of the Deas Slough Bridge south support pier, upland vegetation consists of deciduous, mixed, and coniferous tree woodland (BIEAP - FREMP 2014) dominated by black cottonwood, with an understory of red alder and willow, a shrub layer of salmonberry (*R. spectabilis*) and blackberry, as well as salal (*Gaultheria shallon*), and huckleberry (*Vaccinium* sp.) (Birtwell et al. 1987a).

Intertidal habitat of low (green-coded) to moderate (yellow-coded) productivity also occurs in Deas Slough (**Appendix A, Figure 3**; BIEAP - FREMP 2014) described as follows:

- A short (about 50 m) section of shoreline at the upstream end of the slough at the Delta Deas Rowing Club pier, as well as approximately 300 m of shoreline fronting the Deas Island Yacht Club marina on the south bank, are classified as habitat of moderate productivity (yellow-coded).
- Riprap-armoured shoreline in the vicinity of support piers and pedestals of the existing Deas Slough Bridge on the north and south banks of the slough is characterized as habitat of low (green-coded) to moderate (yellow-coded) productivity.
- The shoreline fronting the dock, boat launch, and haul-out area at the Captain's Cove marina on the south bank of the mouth of Deas Slough is characterized as low-productivity habitat (green-coded).

Aquatic Resources

The vertically stratified nature of Deas Slough perpetuates a shallow, productive, low-salinity environment that is used for rearing and overwintering by a number of fish species. Deas Slough is important rearing habitat for underyearling sockeye salmon, which are present in the slough from April to October, with maximum abundance in late June and late July (Birtwell et al. 1987*b*). Underyearling starry flounder also rear in the lower and, to a lesser extent, in upper Deas Slough in spring and summer, while adult starry flounder are present in the slough in the autumn and winter (Birtwell et al. 1993). Other fish species that have been recorded in Deas Slough include chinook, chum, coho, and pink salmon, prickly sculpin, Pacific staghorn sculpin (*Leptocottus armatus*), slimy sculpin (*C. cognatus*), largescale sucker (*Catostomus macrocheilus*), northern pikeminnow, peamouth, redbelly darter, threespine stickleback, longfin smelt (*Spirinchus thaleichthys*), white sturgeon, mountain whitefish (*Prosopium williamsoni*), and the non-native American shad (*Alosa sapidissima*) (FISS 2014). Refer to **Section 4.2.1** for summaries of the biology, habitat requirements, and status of Pacific salmon, sturgeon, eulachon, trout, and char.

4.2.1.5 Green Slough

Hydrology and Hydraulics

Green Slough drains into the lower Deas Slough and ultimately into the lower Fraser River South Arm. The channel parallels Highway 99 for approximately 155 m from its confluence with Deas Slough until it bends southwest along River Road West for approximately 1.2 km to the Westminster Avenue junction in Delta. Green Slough is outside of Delta's Fraser River dikes; therefore, it is tidally influenced, and flows into the Fraser River are not impeded. The Green Slough pumping station located at 5596 River Road drains agricultural and residential runoff from Crescent Slough into Green Slough.

Green Slough is 15 m to 20 m wide along most of its length, although channel width narrows to about 10 m near the pump station. The channel is characterized as a very low-gradient glide, with fairly uniform depths that range from about 0.9 m to 1.5 m. Water levels and flows are relatively stable throughout the year with no surface turbulence, providing perennially wetted fish habitat. The substrate consists predominantly of fines (silt).

The Green Slough pump station consists of two flood boxes and four pumps of a combined capacity of 6.25 m³/s (LGL et al. 2009). The pumps are not screened to prevent fish entrainment, and no fish deflection or entrainment prevention devices are employed at the station (LGL et al. 2009). The pump station is run in two modes: drainage occurs from late September/late November to mid-May/early June to provide flood protection, while irrigation occurs from mid-May/early June to late September/late November to provide agricultural water supply. The side-hinged flood box flap gates are operated using head differential between the upstream and downstream water levels. They typically close whenever water levels are higher downstream than upstream, i.e., on rising tides (LGL et al. 2009). Slough water levels are manipulated by means of chaining shut the flap gates, inserting stop logs into the flood boxes, or opening a sluice gate or flap gate inset to allow for limited water exchange (LGL et al. 2009). As part of the Delta Irrigation Enhancement Project, the operation of this pump station was modestly modified in 2013 to provide enhanced upstream fish access.

Physical Fish Habitat

Green Slough is classified as an environmentally sensitive area (ESA) under Delta's Official Community Plan. An ESA designation identifies areas of high environmental value requiring protection or mitigation of environmental impacts for any proposed development. As a backwater feature that is tidally influenced, Green Slough provides perennially wetted rearing and overwintering salmonid habitat (LGL et al. 2009). Along Green Slough's length, the riparian buffer is 30 m wide, and overhanging vegetation is ample; however, since it is a very low-gradient glide with a predominance of fines, Green Slough does not offer valuable salmon spawning habitat (LGL et al. 2009).

The shoreline of Green Slough is classified as habitat of high productivity (red-coded) (BIEAP - FREMP 2014). A tidal marsh comprises the lower elevations of the intertidal bench, with vegetation consisting of Lyngbye's sedge, hard-stemmed bulrush, scouring rush (*Equisetum hyemale*), and the non-native purple loosestrife (*Lythrum salicaria*) (BIEAP - FREMP 2014). Riparian vegetation backing the marsh consists of low and tall shrubs of hardhack, red-osier dogwood (*Cornus stolonifera*), non-native Himalayan blackberry and Scotch broom (*Cytisus scoparius*), with isolated areas with black cottonwood (BIEAP - FREMP 2014).

At EastpointPark Reserve, immediately downstream of the Green Slough pump station, marsh habitat was created and the riparian zone was restored with plantings of native vegetation, to compensate for loss of riparian and mudflat habitat as a result of riprap installation and sheet piling in Green Slough during bridge construction at Admiral Blvd (BIEAP - FREMP 2014). Tidal flows were also improved by removing an old wooden culvert that had collapsed (BIEAP - FREMP 2014).

Compensation works were also undertaken in 1997 at the mouth of Green Slough to restore habitat that was disturbed during upgrade and maintenance works within the existing Captain's Cove Marina Ltd. marina facility. Compensation included the creation of an intertidal marsh bench, as well as riparian plantings on top of riprap slope (BIEAP - FREMP 2014).

Aquatic Resources

Fish passage into Green Slough is unobstructed. Although salmonid spawning values do not apply, this backwater feature is expected to provide high-value rearing and overwintering habitat for fish, including Pacific salmon, particularly coho and chinook (LGL et al. 2009). Habitat values for salmonids upstream of the flood box and pump station at the confluence with Crescent Slough is anticipated to be relatively low, given impeded fish access, water withdrawal for agricultural use, and high water temperatures in the summer (LGL et al. 2009).

Historical records of cutthroat trout from Crescent Slough exist from 1983 (FISS 2014); however, no salmonids have been detected in the slough since then. Green Slough is also used by non-salmonid species, such as threespine stickleback, prickly sculpin, redbelly darter, peamouth, and brassy minnow (*Hybognathus hankinsoni*) (FISS 2014). Non-native fish species also reported from Green Slough include brown catfish, black crappie, pumpkinseed (*Lepomis gibbosus*), carp, goldfish (*Carassius auratus*), and largemouth bass (*Micropterus salmoides*) (FISS 2014). Refer to **Section 4.2.1** for summaries of the biology, habitat requirements, and status of Pacific salmon, sturgeon, eulachon, trout, and char.

4.2.1.6 Upland Watercourses

106 upland watercourses were identified within the study area (**Table 4-1**) (see also **Appendix A, Figures 1a through 1p**).

Table 4-1 Upland Watercourses Identified within the Study Area (Listed in Southbound Order)

| Watercourse Reference No. ¹ | Watercourse Name | Watercourse Type | Classification |
|---|---|-------------------------|-----------------------|
| 6 | Bridgeport Road Ditch North | Ditch | Green |
| 7 | Bridgeport Road Ditch South | Swale | Green |
| 8 | Patterson Road Ditch North | Ditch | Yellow |
| 9 | Tuttle Avenue Ditch West | Ditch, permanent | Yellow |
| 10 | Tuttle Avenue Ditch East | Ditch, permanent | Yellow |
| 11 | Highway 99 Ditch West (between Cambie Road and Shell Road) | Swale | Yellow |
| 12 | Shell Road Ditch East, north of Highway 99 | Ditch | Yellow |
| 13 | Highway 99 Ditch East (between Shell Road and Highway 91) | Roadside ditch | Yellow |
| 14 | Highway 99 Ditch Southwest (between Shell Road and Highway 91) | Roadside ditch | Yellow |
| 15 | Highway 99 Ditch Northeast (between Highway 91 and Westminster Highway) | Roadside ditch/Slough | Yellow |
| 16 | Highway 99 Ditch Southeast (between Highway 91 and Westminster Highway) | Roadside ditch/Slough | Yellow |
| 17 | Westminster Highway Ditch North, east of Highway 99 | Ditch | Yellow |
| 18 | Westminster Highway Ditch South, east of Highway 99 | Ditch | Yellow |
| 20 | Highway 99 Ditch East (between Westminster Highway and Blundell Road) | Roadside ditch/Slough | Yellow |

| Watercourse Reference No. ¹ | Watercourse Name | Watercourse Type | Classification |
|--|---|-----------------------|--|
| 21 | Highway 99 Ditch West (between Westminster Highway and Blundell Road) | Roadside ditch/Slough | Yellow |

Note:

¹ Watercourse reference numbers correspond to those shown in **Appendix A**.

Physical Fish Habitat

Detailed habitat assessments were conducted at 33 of 106 minor upland watercourses (**Appendix B, Table 3**) as well as Green Slough. The remaining 73 were assessed using photographs taken in the field and from imagery available online through City of Richmond (Richmond 2014) and DeltaMap (Delta 2002, 2003a, b, 2012). Ditches and sloughs within the study area are low-gradient (≤ 0.5 per cent) with fine sediment substrates. Mesohabitats consist solely of straight runs without any pools or riffles. Overall instream cover was found to be generally limited (absent at 13 sites, trace at 48 sites, and moderate at 42 sites), with the exception of four sites that have abundant cover, i.e., Westminster Highway Ditch South, east of Highway 99; Highway 99 Ditch Southwest (between 64 St and Highway 17); and Burns Drive Cross-Ditch #1. The main cover observed in these watercourses is overhanging and instream vegetation. Instream features provided trace cover at only few sites: trace cover provided by small or large woody debris, deep pools, and undercut banks occur at 11, 12, and 11 sites, respectively. Ninety-three of 107 sites have either no or less than 20 per cent crown closure, nine sites have less than 40 per cent, four have less than 70 per cent, and one has greater than 90 per cent. Riparian vegetation was observed to consist mainly of grassed roadside shoulders, shrubs lining ditch banks, and adjacent agricultural fields.

In Situ Water Quality

Table 4-2 summarizes the spring, summer, and autumn water quality data from upland watercourses sampled within the study area, in relation to the B.C. WQG criteria for temperature, DO, and pH. Water quality data are provided in **Appendix B, Tables 4** through **6**.

All sites sampled in the spring and autumn met the B.C. WQG criteria for temperature; however, all of the sites sampled in summer exceeded the criteria. Dissolved oxygen (DO) concentrations were below the water quality guidelines for at all sites sampled in spring and summer, aside from three in the spring sampling, four in the summer, and 7 in the autumn. The B.C. WQG criteria for pH were met for nine of 25 sites sampled in spring, 13 of 15 sites sampled in the summer, and 11 of 34 sites sampled in autumn. Conductivity varied across sites but was generally low.

Table 4-2 Summary of Water Quality Data for Upland Watercourses Sampled in the Study Area

| Sampling Period (2014) | n | Descriptive Statistic | Temperature (°C) | Dissolved Oxygen (mg/L) | pH | Conductivity (µS/cm) |
|------------------------|----|-----------------------------------|------------------|-------------------------|-------------|----------------------|
| | | B.C. WQG Criteria | 6 – 17 | >5 | 6.5 – 9.0 | n/a |

| | | Range | 7.8 - 14.0 | 0.07 – 5.50 | 4.69 – 7.45 | 100 - 1,764 |
| | | Per cent within B.C. WQG criteria | 100% | 12% | 67% | n/a |
| Summer | 15 | Mean | 20.7 | 2.9 | 7.00 | 2899 |
| | | Range | 17.4 – 25.2 | 0.12 – 8.55 | 6.03 - 7.69 | 135 - 29435 |
| | | Per cent within B.C. WQG criteria | 0% | 27% | 87% | n/a |
| Autumn | 34 | Mean | 13.9 | 3.61 | 6.17 | 492 |
| | | Range | 11.9 – 15.4 | 1.03 - 12.03 | 1.86 - 6.68 | 24 – 2,027 |
| | | Per cent within B.C. WQG criteria | 100% | 21% | 32% | n/a |

Fish Presence and Distribution

Including Crescent Slough, fish presence has been previously documented in 39 of the assessed upland watercourses within the study area (Delta 2002, 2003a, FISS 2014). Crescent Slough and Big Slough are the only watercourses with historic records of CRA species (i.e., cutthroat trout, chinook and coho salmon); however, these capture dates are from 1983 (FISS 2014), and this watercourse is generally considered to be non-salmonid bearing, especially within reaches close to the Highway 99 ROW (Hemmera 2006).

During the spring sampling period, 88 minnow traps were set at 26 sites within the study area for a total of 1,971 hours of sampling effort. In autumn, 88 traps were set in 34 watercourses for a total of 1,994 hours of sampling effort. Species captured include the native species brassy minnow and threespine stickleback, and the non-native brown catfish, goldfish, and pumpkinseed. Historic and recent fish capture data for the study area are summarized in **Table 4-3**.

Notes:

¹ Watercourse reference numbers correspond to those shown in **Appendix A**

- Shaded cells indicate sites where CRA fish have been documented
- NFC = no fish caught
- BCB = black crappie; BH = catfish (general); BMC = brassy minnow; BNH = brown catfish; BS = bass/sunfish (general); CAS = prickly sculpin; CP = carp; CT = cutthroat trout; GC = goldfish; LMB = largemouth bass; PCC = peamouth; PMB = pumpkinseed; RSC = redbside shiner; SB = stickleback (general); TSB = threespine stickleback.
- "-" = no data

The City of Richmond classifies ditches along the west side of Highway 99 south of Westminster Highway flowing towards the Fraser River South Arm as salmon-bearing. Along the east side of Highway 99, salmon-bearing status is assigned to ditches south of Bridgeport Road to Steveston Highway. However, no salmonid species have been previously documented within Richmond ditches (FISS 2014), and extensive sampling efforts in the study area in 2014 did not result in capture of salmonids. Connectivity of these ditches to the Fraser River South Arm appears to be very limited by the presence of pump stations and flood boxes. Located at the south end of Highway 99 Ditch West (between Steveston Highway and Fraser River), and at the intersection of Steveston Highway and No. 6 Road, this flood-control infrastructure appears to pose considerable restrictions to salmonid access into this ditch network. Connectivity and distance of the watercourses from the Fraser River South Arm are also expected to limit access and use. Classification of these watercourses according to the codes and definitions presented in **Table 3-2** reflects these limitations on fish access, results of fish sampling efforts in 2014, and low fish habitat values, which includes relatively poor water quality observed in ditches within the study area.

North of the Fraser River South Arm, Highway 99 Ditch West (between Steveston Highway and Fraser River South Arm) is classified as dashed-red, and Highway 99 Ditch East (between Steveston Highway and Fraser River South Arm) as yellow. Jacobsen Way/Hartnell Road Ditch is also classified as dashed-red, because it has the potential to flow directly into Highway 99 Ditch West (between Steveston Highway and Fraser River) (**Appendix A, Figure 1f**). North of Steveston Highway, Highway 99 ditches are classified as orange until King Road, and yellow north of that location (**Appendix A, Figure 1b-1f**).

South of Fraser River South Arm and its well-connected Deas and Green sloughs, Delta catchment areas FA-5 and FA-5 overlap with the study area and have some potential to support salmonid species, such as cutthroat trout. Salmonid presence was documented more than 30 years ago (Delta 2003a, FISS 2014); however, previous sampling conducted for the Ministry's South Fraser Perimeter Road (SFPR) project and sampling efforts applied in 2014 did not result in the capture of any salmonids. Access to these Delta ditches by salmonids from the Lower Fraser River/Green Slough is likely impaired by flood-control infrastructure. Flows into Crescent Slough are limited by a flood box and pump station at the confluence with Green Slough (LGL et al. 2009). In classifying these ditches, consideration was given to distance from Green Slough. Ditches from Deas Slough to Highway 17A are therefore classified as dashed-red; ditches east of Highway 17A are not continuous with those west of Highway 17A and are classified as yellow and orange.

4.3 Incidental Observations

Incidental observations include aquatic and terrestrial wildlife other than fish that were either captured in minnow traps or observed during the course of the field work. Amphibian captures include the non-native American bullfrog (*Lithobates catesbeianus*), green frog (*L. clamatans*), and northwestern salamander (*Ambystoma gracile*). Invertebrate captures include dragonfly naiads (*Aeshna* sp.), water beetles, aquatic snails, and leeches (Table 4-4).

Table 4-4 Summary of Incidental Observations of Aquatic Organisms

| Common Name | Scientific Taxon | Count | |
|--|--|--------|--------|
| | | Spring | Autumn |
| Amphibians | | | |
| American bullfrog and/or green frog tadpoles | <i>Lithobates</i> spp. | 65 | ~380 |
| Northwestern salamander | <i>Ambystoma gracile</i> | - | 1 |
| Invertebrates | | | |
| Aquatic snails | Phylum Mollusca, Class Gastropoda | 9 | ~120 |
| Beetle | Order Coleoptera | 7 | 29 |
| Dragonfly naiads | <i>Aeshna</i> sp. | 2 | - |
| Freshwater leeches | Phylum Annelida, Subclass Hirudinea | 9 | 70 |

Notes: “-” indicates no incidental captures

Field crews took particular care to look for autumn meadowhawk (*Sympetrum vicinum*), a provincially Blue-listed dragonfly species (B.C. CDC 2015), and signs of Pacific water shrew (*Sorex bendirii*), a semi-aquatic mammal species that is provincially Red-listed (B.C. CDC 2015), listed as Endangered under SARA Schedule 1 (Government of Canada 2013), and designated as Endangered by COSEWIC (2006). However, none were observed. Table 4-5 provides a summary of terrestrial wildlife incidental observations.

Table 4-5 Summary of Incidental Observations of Terrestrial Wildlife

| Species | Location Observed | Number Observed/ Comments |
|--|--|------------------------------|
| Mallard (<i>Anas platyrhynchos</i>) | Highway 99 Ditch West (between Steveston Highway and Fraser River) | 1 |

5.0 Discussion

The major results arising from the information review and field freshwater fish and fish habitat study of existing conditions are discussed below.

5.1 Key Findings

5.1.1 Commercial, Recreational, or Aboriginal Fish Values

The review of existing information confirmed that extensive fish and fish habitat information is available for the major watercourses that intersect the study area, including the lower Fraser River, specifically South Arm, and Deas and Green sloughs. Major watercourses have suitable habitat to meet the life history needs of various fish species that are considered to have CRA fisheries values. The full list of CRA fish species that occur within the study area includes five species of Pacific salmon (coho, chinook, chum, pink, and sockeye), two species of trout (coastal cutthroat, and rainbow/steelhead), two species of char (Dolly Varden and bull trout), two species of sturgeon (green and white), and eulachon.

The Fraser River South Arm and tidal features in the lower river reaches (e.g., Deas and Green sloughs) are well-documented as providing important habitat values for all of the aforementioned CRA fish species. Most notably, the lower river is a significant upstream migration corridor for adult Pacific salmon and a rearing habitat corridor for out-migrating juveniles. Juvenile salmon (especially chinook, chum, and to a lesser extent coho) receive considerable feeding and refuge benefits from key estuarine tidal habitats, in particular tidal marshes and adjacent un-vegetated flats, as they move downstream into the lower estuary. These same river reaches and well-connected tidal backwaters also provide important habitat values for various life history stages of coastal cutthroat trout, rainbow trout (including steelhead), white sturgeon, and eulachon. Adult green sturgeon also potentially occur, but in low numbers and primarily in the lower estuary.

Upland watercourses within the study area comprise mainly roadside or agricultural ditches. Fish access into these ditches is typically limited by flood control infrastructure (i.e., dikes with pump stations and flood boxes), which impacts their connectivity to higher-value CRA fish waters located further downstream. With specific consideration towards salmonids (i.e., Pacific salmon, trout and char), which are the most likely CRA fish to occur in these ditches, low gradients and finer streambed substrates preclude any potential for spawning. The most likely life history stage of salmonids that would inhabit these ditches are juvenile fish, in particular rearing juvenile Pacific salmon (e.g., chinook and coho salmon). Based on fieldwork in 2014, water quality tends to be quite poor seasonally, with relatively high water temperatures, low

DO concentrations, and seasonally acidic pH levels. These conditions are expected to preclude or deter the use of these watercourses by rearing salmonids, except during winter months when more suitable water quality conditions may occur.

Although fish sampling occurred at 61 sites during the spring and autumn 2014, when water levels and water quality should have been most suitable for salmonids, no salmonids were caught in upland ditches within the study area.

All of the watercourses within the study area were classified based on a classification scheme that focuses primarily on CRA fisheries values. Watercourse reaches with CRA values are described in this report and mapped in the appended watercourse classification maps (**Appendix A**) as year-round CRA fish habitats (red-coded), seasonal CRA fish habitats (dashed-red-coded), or as a significant upstream source of food and nutrients to CRA fish habitats (orange-coded). For the upland watercourses, this coding is generally based on potential rather than confirmed CRA fish habitat values. Furthermore, it is noted that potential habitat use by CRA fish is considered to decrease with distance from downstream confirmed CRA fish habitats into which these watercourses drain. This assumption is based on the best professional judgement of this report's authors; additional fieldwork would be required to more definitely characterize the full distribution of CRA fish.

5.1.2 Non-Commercial, Recreational, or Aboriginal Fish Values

With the exception of major watercourses and a select few minor upland watercourses within the study area, the majority of the remaining watercourses are low-gradient channelized ditches characterized by fine bottom substrates and poor connectivity to downstream CRA waters. Additionally, the use of these watercourses by fish may be limited by poor water quality conditions, in particular high temperatures and low DO levels. In the warmer summer months, these poor water quality conditions would presumably be heightened due to lower flows, higher water temperatures, and lower DO concentrations. As a result, some of these ditches may not support any fish (even resident fish) on a year-round basis.

Numerous different resident fish species have been previously documented within the study area (refer to **Appendix B, Table 1**); however, fish fauna captured by minnow trapping in 2014 were limited to three native fish species (threespine stickleback, brassy minnow, and bull trout) and two introduced fish species (goldfish and pumpkinseed). All of these fish, in particular threespine stickleback and the three introduced species, are known to be tolerant of poor water quality conditions and therefore are not unexpected within the study area.

Based on the watercourse classification scheme developed for this study, non-CRA watercourse reaches are described in this report and mapped in the accompanying watercourse classification maps (**Appendix A**) as resident fish habitats (yellow-coded) or non-fish bearing habitats (green-coded). The majority of the watercourses overlapping with the Project alignment have non-CRA fish habitat values.

Legend

- Burns Bog Ecological Conservancy Area
- Waterbody
- Canada - U.S. Border
- Highway
- Arterial/Collector Road
- High Productivity Habitat
- Moderate Productivity Habitat
- Low Productivity Habitat
- deciduous tree woodland
- coniferous tree woodland
- mixed tree woodland
- low shrub woodland
- tall shrub woodland
- meadow, vascular
- meadow, non-vascular
- marsh
- eel-grass
- macroalgae
- mud
- sand
- rock
- other
- habitat compensation site

SOURCES
 Parks and Protected Lands, First Nations Reserves from GeoBC, United States basemap data courtesy of USGS. Burns Bog courtesy of The Corporation of Delta and based on the Metro Vancouver Burns Bog Ecological Conservancy Area Management Plan - May 2007, all other data courtesy of Canvec - GeoGratis. All other data obtained from the Fraser River Estuary Management Program & Burrard Inlet Environmental Action Program Habitat Atlas available online through the Community Mapping Network (http://www.cmnbc.ca/atlas_gallery/fremp-bieap-habitat-atlas). Data was accessed in November 2014. Productivity data was digitized at a scale of 1:5000 and is an approximate representation only.

Table B2 Complete List of Fish Species Previously Documented Within the Study Area

| Common Name | Scientific Name | Species Code | Comments |
|--|-------------------------------------|--------------|----------|
| Native Species | | | |
| Anadromous cutthroat trout | <i>Oncorhynchus clarki</i> | ACT | - |
| Brassy Minnow | <i>Hybognathus hankinsoni</i> | BMC | - |
| Bull Trout | <i>Salvelinus confluentus</i> | BT | - |
| Chinook Salmon | <i>Oncorhynchus tshawytscha</i> | CH | - |
| Chub, General | | CBC | |
| Chum Salmon | <i>Oncorhynchus keta</i> | CM | - |
| Coastal Cutthroat Trout | <i>Oncorhynchus clarkii clarkii</i> | CCT | - |
| Coastrange Sculpin (formerly Aleutian Sculpin) | <i>Cottus aleuticus</i> | CAL | - |
| Coho Salmon | <i>Oncorhynchus kisutch</i> | CO | - |
| Cutthroat Trout, General | <i>Oncorhynchus clarki</i> | CT | |
| Dolly Varden | <i>Salvelinus malma</i> | DV | - |
| Eulachon | <i>Thaleichthys pacificus</i> | EU | - |
| Green Sturgeon | <i>Acipenser medirostris</i> | GSG | - |
| Kokanee | <i>Oncorhynchus nerka</i> | KO | - |
| Lamprey | <i>Lampetra</i> spp. | L | - |
| Largescale Sucker | <i>Catostomus macrocheilus</i> | CSU | - |
| Leopard Dace | <i>Rhinichthys falcatus</i> | LDC | - |

| Common Name | Scientific Name | Species Code | Comments |
|----------------------------------|----------------------------------|--------------|--|
| Longfin Smelt | <i>Spirinchus thaleichthys</i> | LSM | - |
| Longnose Sucker | <i>Catostomus catostomus</i> | LSU | Species in the lower Fraser Valley is genetically distinct from <i>C. catostomus</i> |
| Longnose Dace | <i>Rhinichthys cataractae</i> | LNC | Those in Fraser system are genetically distinct from Nooksack tributaries |
| Mountain Whitefish | <i>Prosopium williamsoni</i> | MW | - |
| Northern Pikeminnow | <i>Ptychocheilus oregonensis</i> | NSC | - |
| Pacific Lamprey | <i>Lampetra tridentata</i> | PL | - |
| Peamouth Chub | <i>Mylocheilus caurinus</i> | PCC | - |
| Pink Salmon | <i>Oncorhynchus gorbuscha</i> | PK | - |
| Prickly Sculpin | <i>Cottus asper</i> | CAS | - |
| Rainbow Trout | <i>Oncorhynchus mykiss</i> | RB | - |
| Redside Shiner | <i>Richardsonius balteatus</i> | RSC | - |
| River Lamprey | <i>Lampetra ayresii</i> | RL | - |
| Sculpins, General | <i>Cottus spp</i> | CC | - |
| Sockeye Salmon | <i>Oncorhynchus nerka</i> | SO | - |
| Species Present (not identified) | <i>n/a</i> | SP | - |
| Staghorn Sculpin | <i>Leptocottus armatus</i> | CLA | Estuarine or Tidal (McPhail and Corveth 1993) |
| Starry Flounder | <i>Platichthys stellatus</i> | SFL | Estuarine or Tidal (McPhail and Corveth 1993) |
| Steelhead | <i>Oncorhynchus mykiss</i> | ST | - |

| Common Name | Scientific Name | Species Code | Comments |
|---|---------------------------------|--------------|--|
| Surf Smelt | <i>Hypomesus pretiosus</i> | none | - |
| Threespine Stickleback | <i>Gasterosteus aculeatus</i> | TSB | - |
| Western Brook Lamprey | <i>Lampetra richardsoni</i> | BL | - |
| White Sturgeon | <i>Acipenser transmontanus</i> | WSU | - |
| Native Species | | | |
| Bridgelip Sucker | <i>Catostomus columbianus</i> | BSU | Presence in lower Fraser known from a single specimen (McPhail and Corveth 1993) |
| Burbot | <i>Lota lota</i> | BT | Peripheral range only (iMap BC 2014), presence in lower Fraser known from a single specimen (McPhail and Corveth 1993) |
| Lake Trout | <i>Salvelinus namaycush</i> | LT | Exotic in study area (iMap BC 2014), presence in lower Fraser known from a single specimen (McPhail and Corveth 1993) |
| Northern Mountain Sucker | <i>Catostomus platyrhynchus</i> | MSU | Presence in lower Fraser known from a single specimen (McPhail and Corveth 1993) |
| Introduced Species | | | |
| American Shad | <i>Alosa sapidissima</i> | SH | - |
| Black Crappie | <i>Pomoxis nigromaculatus</i> | BCB | - |
| Brook Trout | <i>Salvelinus fontinalis</i> | EB | - |
| Brown Catfish (formerly Brown Bullhead) | <i>Ameiurus nebulosus</i> | BNH | - |
| Catfish | - | BH | - |
| Carp | <i>Cyprinus carpio</i> | CP | - |
| Fathead Minnow | <i>Pimephales promelas</i> | FM | - |

| Common Name | Scientific Name | Species Code | Comments |
|--------------------|---------------------------------------|---------------------|-----------------|
| Golden Trout | <i>Oncorhynchus mykiss aguabonita</i> | GT | - |
| Goldfish | <i>Carassius auratus</i> | GC | - |
| Lake Whitefish | <i>Coregonus clupeaformis</i> | LW | - |
| Largemouth Bass | <i>Micropterus salmoides</i> | LMB | - |
| Pumpkinseed | <i>Lepomis gibbosus</i> | PMB | - |

ATTACHMENT C

Photographs of Watercourses Assessed during the Fish Field Program for the Project

Photo 1: Swale that runs to the north from Bridgeport Road North (Watercourse #6), looking south. April 1, 2014.

Photo 2: Representative photo of Bridgeport Road Ditch South (Watercourse #7), facing south. April 2, 2014.

Photo 3: Representative photo of Patterson Road Ditch North (Watercourse #8), facing west. July 14, 2014.

Photo 4: Representative photo of Tuttle Avenue Ditch West (Watercourse #9), facing upstream. April 1, 2014.

Photo 5: Representative photo of Tuttle Avenue Ditch East (Watercourse #10), facing downstream. October 17, 2014.

Photo 6: Representative photo of Highway 99 Ditch West (between Cambie & Shell) (Watercourse #11), facing northwest. October 17, 2014.

Photo 7: Representative photo of Shell Road Ditch East, north of Highway 99 (Watercourse #12), facing north. October 17, 2014.

Photo 8: Representative photo of Highway 99 Ditch East (between Shell & Highway 91) (Watercourse #13), facing northwest. October 17, 2014.

Photo 9: Representative photo of Highway 99 Ditch Southwest (between Shell & Highway 91) (Watercourse #14), facing southeast. October 17, 2014.

Photo 10: Representative photo of Highway 99 Ditch Northeast (between Highway 91 & Westminster Highway) (Watercourse #15), facing north. October 19, 2014.

Photo 11: Representative photo of Highway 99 Ditch Southeast (between Highway 91 and Westminster Highway) (Watercourse #16), facing north. April 1, 2014.

Photo 12: Representative photo of Westminster Highway Ditch North, east of Highway 99 (Watercourse #17), facing west. April 21, 2014.

Photo 13: Representative photo of Westminster Highway Ditch South, east of Highway 99 (Watercourse # 18), facing east. July 14, 2014.

Photo 14: Representative photo of Highway 99 Ditch East (between Westminster Highway and Blundell Road) (Watercourse #20), facing north. October 17, 2014.

Photo 15: Representative photo of Highway 99 Ditch West (between Westminster Highway and Blundell Road) (Watercourse #21), facing north. April 1, 2014.

Photo 16: Representative photo of Blundell Road Ditch South, east of Highway 99 (Watercourse #22), facing east. April 21, 2014.

Photo 17: Representative photo of Highway 99 Ditch East (between Blundell Road and Steveston Highway) (Watercourse #23), facing south from Williams Road Ditch. April 21, 2014.

Photo 18: Representative photo of Highway 99 Ditch West (between Blundell Road and Steveston Highway) (Watercourse #24), facing north. April 1, 2014.

Photo 19: Looking east at Richmond Agricultural Ditch #1 from Highway 99 (Watercourse #25).
October 17, 2014.

Photo 20: Looking east at Richmond Agricultural Ditch #2 (Watercourse #26) from Highway 99.
October 17, 2014.

Photo 21: Looking east at Richmond Agricultural Ditch #3 (Watercourse #27) from Highway 99. October 17, 2014.

Photo 22: Looking west toward Richmond Agricultural Ditch #4 (Watercourse #28) from Highway 99. October 17, 2014.

Photo 23: Looking west toward Richmond Agricultural Ditch #5 (Watercourse #29) from Highway 99. October 17, 2014.

Photo 24: Looking west toward Richmond Agricultural Ditch #6 (Watercourse #30) from Highway 99. October 17, 2014.

Photo 25: Looking east at Richmond Agricultural Ditch #7, east of Highway 99 (Watercourse #31). October 17, 2014.

Photo 26: Looking east at Richmond Agricultural Ditch #7, west of Highway 99 (Watercourse #32) from No.5 Road. October 17, 2014.

Photo 27: Looking west from Highway 99 at King Road Ditch, west of Highway 99 (Watercourse #33).
April 1, 2014.

Photo 28: Looking east from Highway 99 at King Road Ditch, east of Highway 99 (Watercourse #34).
October 17, 2014.

Photo 29: Looking east from Highway 99 at Williams Road Ditch (Watercourse #35), east of Highway 99. April 21, 2014.

Photo 30: Looking west from Highway 99 at Williams Road Ditch, west of Highway 99 (Watercourse #36). April 21, 2014.

Photo 31: Looking east from No.5 Road at Richmond Agricultural Ditch #8 (Watercourse #37).
October 17, 2014.

Photo 32: Looking east from Highway 99 at Richmond Agricultural Ditch #9 (Watercourse #38).
October 17, 2014.

Photo 33: Representative photo of Steveston Highway Ditch North, east of Highway 99 (Watercourse #39), facing west. April 21, 2014.

Photo 34: Representative photo of Steveston Highway Interchange Northwest Ditch (Watercourse #40), facing east. October 17, 2014.

Photo 35: Representative photo of Steveston Highway Ditch South, east of Highway 99 (Watercourse #41), facing west. July 14, 2014.

Photo 36: View of Steveston Highway Interchange Southeast Ditch (Watercourse #42), facing west. October 17, 2014.

Photo 37: Representative photo of Highway 99 Ditch East (between Steveston and Fraser River) (Watercourse #43), facing south. October 17, 2014.

Photo 38: Representative photo of Highway 99 Ditch West (between Steveston and Fraser River) (Watercourse #44), facing south from Rice Mill Road. April 21, 2014.

Photo 39: Representative photo of Richmond Agricultural Ditch #10 (Watercourse #45), facing northeast. April 21, 2014.

Photo 40: Representative photo of Jacobsen Way/Hartnell Road Ditch (Watercourse #46), facing west. April 21, 2014.

Photo 41: Representative photo of Richmond Agricultural Ditch #11 ((Watercourse #47), facing west. October 18, 2014.

Photo 42: Representative photo of Rice Mill Road Ditch North, facing west (Watercourse #48). April 21, 2014.

Photo 43: Representative photo of Rice Mill Road Ditch South (Watercourse #49), facing west. April 21, 2014.

Photo 44: Fraser River South Arm (Watercourse #50), facing downstream from south bank. February 19, 2014.

Photo 45: Fraser River South Arm (Watercourse #50), facing towards north bank from south bank. February 19, 2014.

Photo 46: Riprap armoring on intermittent sections of River South Arm south bank. February 19, 2014.

Photo 47: Fraser River South Arm (Watercourse #50), facing towards south bank from north bank. February 19, 2014.

Photo 48: Deas Slough (Watercourse #51), facing downstream from south bank at Highway 99. February 19, 2014.

Photo 49: Deas Slough (Watercourse #51), facing upstream from south bank at Highway 99. February 19, 2014.

Photo 50: Green Slough (Watercourse #52), facing upstream from left bank. July 16, 2014.

Photo 51: Facing downstream at Green Slough (Watercourse #52) towards outlet to Deas Slough. July 16, 2014

Photo 52: Representative photo of River Road Ditch Northwest (Watercourse #53), north of Highway 99, looking northeast. April 21, 2014.

Photo 53: Representative Photo of River Road Ditch Southeast, south of Highway 99 (Watercourse #54), looking west. April 1, 2014.

Photo 54: Representative photo of Highway 99 Ditch Northeast (between River Rd and 17A) (Watercourse #55), facing northwest. October 17, 2014.

Photo 55: Representative photo of Highway 99 Ditch Southwest (between River Rd and 17A) (Watercourse #56) taken from River Road, looking southeast. April 1, 2014.

Photo 56: Looking southeast at Highway 99 Ditch Northeast (between 17A and 64 St) (Watercourse #57) from River Road exit. October 19, 2014.

Photo 57: Representative photo of Highway 99 Ditch Southwest (between Highway 17A and 64 St) (Watercourse #58), facing northwest. April 1, 2014.

Photo 58: Representative photo of Delta Agricultural Ditch #1 (Watercourse #59), facing south. April 2, 2014.

Photo 59: Representative photo of Burns Drive Ditch Northeast (between 64 St and Highway 17) (Watercourse #60), facing east. April 15, 2014.

Photo 60: Representative photo of Highway 99 Ditch Southwest (between 64 St and Highway 17) (Watercourse #61), facing southeast from Crescent Slough. October 19, 2014.

Photo 61: Representative photo of 64 Street Ditch East, north of Highway 99 (Watercourse #62), facing north. April 15, 2014.

Photo 62: Representative photo of Delta Agricultural Ditch # 2 (Watercourse #64), taken from 64 Street looking east. April 1, 2014.

Photo 63: Looking south from Highway 99 at Delta Agricultural Ditch #4 (Watercourse #65). October 18, 2014.

Photo 64: Representative photo of Crescent Slough, northeast of Highway 99 (Watercourse #66), facing northeast. October 18, 2014.

Photo 65: Representative photo of Crescent Slough, southwest of Highway 99, facing south (Watercourse #67). July 15, 2014.

Photo 66: Representative photo of Highway 99 Ditch North (between Highway 17 and Ladner Trunk Road) (Watercourse #68), facing west. October 18, 2014.

Photo 67: Representative photo of Highway 99 Ditch South (between Highway 17 and Ladner Trunk Road) (Watercourse #69), looking east from 88 Street.

Photo 68: Representative photo of Delta Agricultural Ditch #6 (Watercourse #70), facing south. July 15, 2014.

Photo 69: Representative photo of SFPR Ditch West, north of Highway 99 (Watercourse #71), facing southwest. July 15, 2014.

Photo 70: Representative photo of Delta Agricultural Ditch #7 (Watercourse #72), facing south. October 17, 2014.

Photo 71: Representative photo of Delta Agricultural Ditch #8 7 (Watercourse #73), facing south. October 17, 2014.

Photo 72: Representative photo of Delta Agricultural Ditch #9 7 (Watercourse #74), facing south. October 17, 2014.

Photo 73: Representative photo of 72 Street Ditch West, south of Highway 99 (Watercourse #75), facing north. October 17, 2014.

Photo 74: Representative photo of 72 Street Ditch East, south of Highway 99 (Watercourse #76), facing south. July 15, 2014.

Photo 75: Representative photo of Delta Agricultural Ditch #10 (Watercourse #77), looking north. October 20, 2014.

Photo 76: Representative photo of Delta Agricultural Ditch #11 99 (Watercourse #78), looking north from Ladner Trunk Road. April 1, 2014.

Photo 77: Representative photo of 80 street Ditch West, south of Highway 99 (Watercourse #79), looking south from Ladner Trunk Road. October 17, 2014.

Photo 78: Representative photo of 80 street Ditch East, south of Highway 99 (Watercourse #80), looking south from Ladner Trunk Road. October 17, 2014.

Photo 79: Looking west at Burns Drive Ditch North (between Highway 17 and Ladner Trunk Road) (Watercourse #81) from Ladner Trunk Road exit. October 18, 2014.

Photo 80: Looking north from Burns Drive at Burns Drive Cross-ditch #1 99 (Watercourse #82).
October 18, 2014.

Photo 81: Looking north from Burns Drive at Burns Drive Cross-ditch #2 (Watercourse #83).
October 18, 2014.

Photo 82: Representative photo of 88 Street Ditch East, north of Highway 99 (Watercourse #86), facing south. April 15, 2014.

Photo 83: Representative photo of 88 Street Ditch East, south of Highway 99 (Watercourse #87), looking north. April 1, 2014.

Photo 84: Representative photo of 88 Street Ditch West, north of Highway 99 (Watercourse #88), facing north. April 15, 2014.

Photo 85: Representative photo of 88 Street Ditch West, south of Highway 99 (Watercourse #89). Taken from Ladner Trunk Road looking north. April 1, 2014.

Photo 86: Representative photo of Delta Agricultural Ditch #18 (Watercourse #90), facing north. October 17, 2014.

Photo 87: Representative photo of Delta Agricultural Ditch #14 (Watercourse #91), facing north. October 18, 2014.

Photo 88: Representative photo of Delta Agricultural Ditch #15 north of Highway 99 (Watercourse #92). Taken from Burns Drive, facing north. April 15, 2014.

Photo 89: Looking south from Burns Drive at Delta Agricultural Ditch #15 (Watercourse #93), south of Highway 99. October 15, 2014.

Photo 90: Representative photo of Delta Agricultural Ditch #17 (Watercourse #94), facing north. July 15, 2014.

Photo 91: View of Ladner Trunk Road Interchange Southwest, Inner Ditch (Watercourse #95), facing east. October 18, 2014.

Photo 92: View of Ladner Trunk Road Interchange Southeast Inner Ditch (Watercourse #96), facing east. October 18, 2014.

Photo 93: View of Ladner Trunk Road Interchange Northwest Outer Ditch (Watercourse #97), facing west. October 18, 2014.

Photo 94: View of Ladner Trunk Road Interchange Northeast Inner Ditch (Watercourse #98), facing west. October 18, 2014.

Photo 95: View of Ladner Trunk Road Interchange Northeast Outer Ditch (Watercourse #99), facing southwest. October 18, 2014.

Photo 96: View of Ladner Trunk Road Ditch North, east of 96 Street (Watercourse #100), facing north from Ladner Trunk Road. October 18, 2014.

Photo 97: Representative photo of Highway 99 Ditch North (between Ladner Trunk Road and Highway 91) (Watercourse #102), facing east. October 15, 2014.

Photo 98: Representative photo of Highway 99 Ditch South (between Ladner Trunk Road and Highway 91) (Watercourse #103). Facing east from 104 Street Ditch. October 15, 2014.

Photo 99: Representative photo of Delta Agricultural Ditch #16 (Watercourse #104). From Highway 99, looking north from Highway 99. July 15, 2014.

Photo 100: Representative photo of 104 Street Ditch (Watercourse #105), facing south on north side of Highway 99. July 15, 2014.

Photo 101: Representative photo of BNSF Ditch (Watercourse #106). Taken from Highway 99 facing northeast. July 15, 2014.

Photo 102: Representative photo of Big Slough, south of Highway 99 (Watercourse #107), facing north from Ladner Trunk Road. July 15, 2014.

Photo 103: Representative photo of Big Slough, north of Highway 99 (Watercourse #108), facing north. October 18, 2014.

Photo 104: Representative photo of 112 Street Ditch, north of Highway 99 (Watercourse #109). Facing north. July 15, 2014.

Photo 105: Representative photo of 112 Street Ditch, south of Highway 99 (Watercourse #110). Taken from Ladner Trunk road looking north. April 1, 2014.

Photo 106: Representative photo of Oliver Slough, north of Highway 99 (Watercourse # 111), facing north. July 15, 2014.

Photo 107: Representative photo of Highway 91 Interchange Ditches, south of Highway 99 (Watercourse #112). Facing southwest from east side of interchange. October 17, 2014.

Photo 108: Representative photo of Highway 91 Interchange South Outer Ditch (Watercourse #113), facing west from Highway 91 overpass. October 17, 2014.

Photo 109: Representative photo of Eugene Creek, north of Highway 99 (Watercourse #114), facing west. July 15, 2014.

Photo 110: Representative photo of Eugene Creek Diversion (Watercourse #115), facing north. July 15, 2014.

Photo 111: Representative photo of Highway 99 Ditch South (between Highway 91 and Peacock Brook) (Watercourse #116), facing east. April 15, 2014.

Photo 112: Representative photo of Highway 99 Ditch North (between Highway 91 and Peacock Brook) (Watercourse #117), facing east from 131A Street Ditch. April 21, 2014.

| UTM | Universal Transverse Mercator |
| VkmT | vehicle kilometres travelled |
| VOC | volatile organic compounds (excluding methane and ethane) |

Glossary

| Term | Definition |
|------------------------------|--|
| air pollutant | Any pollution agent or combination of such agents, including any physical, chemical, biological, radioactive (including source material, special nuclear material, and by-product material) substance or matter that is emitted into or otherwise enters the ambient air. |
| ambient air | Outdoor or open air. |
| annual average daily traffic | Total traffic measured over a one-year period divided by 365. |
| CALINE | California Line Source dispersion model; a steady-state Gaussian dispersion model designed to determine air pollution concentrations at receptor locations downwind of highways located in relatively uncomplicated terrain. |
| CALMET | A diagnostic three-dimensional meteorological model, the development of which was originally sponsored by the California Air Resources Board. |
| criteria air contaminant | A group of seven pollutants that are emitted predominantly into the air, and cause air issues such as smog and acid rain through their presence or interaction between one another. These seven contaminants are total PM, inhalable PM (PM ₁₀), fine PM (PM _{2.5}), CO, NO ₂ , SO ₂ , and VOCs. A brief description of each CAC is provided in this glossary. |
| emission | The act of releasing or discharging air contaminants into the ambient air from any source. |
| emission factor | An emission factor is defined as the average emission rate of a given pollutant for a given source, relative to units of activity (e.g., kg of SO ₂ emitted per kilometre travelled). |
| emission inventory | An emission inventory is a comprehensive account of air contaminant emissions and associated data from sources within the inventory area over a specified timeframe, which can be used to determine the effect of emissions on ambient air quality. |
| heavy-duty vehicle | A motor vehicle that is designed primarily for transportation of heavy goods (includes heavy-duty haul and refuse trucks). |
| light-duty vehicle | A motor vehicle that is designed primarily for transportation of persons and has a designated seating capacity of not more than 12 persons (includes light-duty gasoline vehicles and light-duty diesel vehicles). |

| Term | Definition |
|---------------------------|---|
| mesoscale | The scale of meteorological phenomena that range in size from a few kilometres to about 100 km. It includes local winds, thunderstorms, and tornadoes. |
| nitrogen oxides | Consist of nitric oxide (NO) and nitrogen dioxide (NO ₂); reported as the equivalent NO ₂ . |
| particulate matter | Any aerosol that is released to the atmosphere in either solid or liquid form. |
| point source | Major stationary emission sources discharging from a stack. |
| receptor | A geographic location for which a computer model calculates a value (eg. ambient concentration of a pollutant). |
| secondary particulate | A contaminant formed by chemical reactions of gaseous contaminants in the air. |
| sulphur oxides | Gaseous sulphur dioxide (SO ₂), for which national and provincial air quality objectives and regulations are in effect. Particulate or aerosol sulphate is excluded from emissions totals and is included under particulate matter. SO _x is reported as SO ₂ -equivalent. |
| volatile organic compound | Photochemically reactive hydrocarbons, excluding methane, ethane, acetone, methylene chloride, methyl chloroform, and several chlorinated organics, because of their low reactivity in the atmosphere (definition used by the U.S. EPA). |

1.0 Scope of Study

This appendix provides supplemental technical information on the air quality study undertaken to support the assessment of effects of the George Massey Tunnel Replacement Project (the Project) on human health and inform the selection of strategies for mitigating such effects. This appendix describes the contaminants assessed, the applicable objectives and standards, study methods, and study results.

As is typical for most air quality assessments, the study comprised two components: emissions estimates and air quality dispersion modelling. Generally, emissions estimates encompass the identification of potential emission sources associated with a project, determination of the types and magnitudes of air contaminants emanating from project sources, and evaluation of the relative contribution of these emissions on contaminant loading in the project region. Dispersion modelling uses the emissions estimates to provide a prediction of the potential effects a project may have on local air quality in the future.

The B.C. Modelling Guideline, which outlines recommended steps (e.g. development of a conceptual as well as a detailed model plan) for completing modelling projects, was used to guide Project-related air-quality modelling. Metro Vancouver was involved in the model planning discussions from the early stages of model planning, and this consultation helped identify and address some of the issues noted in this assessment. A copy of the detailed modelling plan is provided as **Attachment A**.

2.0 Emission Parameters

2.1 Air Contaminant Characteristics

Vehicles emit CACs and TACs as a result of fossil fuel combustion. While vehicle tailpipe emissions and road dust from vehicle traffic yield air contaminants that affect air quality, the combustion of fuels from construction equipment and process combustion units, such as those in asphalt plants, produce a range of similar gaseous and particulate matter contaminants. Collectively, these contaminants may directly or indirectly act as precursors to the formation of other gases and particles in the atmosphere, which may have potential effects on human health and the environment. The key characteristics associated with these air contaminants resulting from fuel combustion are provided below.

2.1.1 Sulphur Dioxide

Sulphur is present in fossil fuels and is transformed into SO_2 , a colourless gas that has a strong odour at elevated concentrations during the process of combustion.

2.1.2 Nitrogen Oxides

Oxides of nitrogen (NO_x) are a mixture of nitrogen dioxide (NO_2) and nitric oxide (NO). High temperature combustion processes typically emit 94 to 97 per cent of the NO_x as NO , with the remaining balance as NO_2 . Once emitted, NO reacts with the oxygen in air to form NO_2 .

Nitrogen dioxide is an important precursor to ground-level ozone formation that occurs through photochemical reactions involving VOCs. Elevated concentrations of NO_2 produce a brownish gas that is visible in the atmosphere. As the NO_2 reacts in the atmosphere with ammonia, fine particulate salts are formed, which increase $\text{PM}_{2.5}$ concentrations and reduce visibility.

2.1.3 Ammonia

Ammonia is a colourless gas that is a product of internal engine combustion, and is also widely used in industry to produce nitrogen-based products such as fertilizers, plastics, and explosives. It is one of the common air contaminants included in regional emissions inventories because of its role in the formation of secondary particulates. Agricultural operations are the major source of ammonia released to the atmosphere.

2.1.4 Carbon Monoxide

Carbon monoxide is a clear, odourless gas that reduces the blood's capacity to carry oxygen to tissues in the body. Carbon monoxide also participates to a minor extent in photochemical smog reactions that lead to increased ground-level ozone formation. Proper design and operation of combustion equipment helps keep CO emission levels and ambient concentrations at low levels.

2.1.5 Particulate Matter

Particulate matter (PM, PM₁₀, PM_{2.5}) includes mineral, carbonaceous, and other types of particles, as well as a mix of chemical compounds that may be adsorbed or adhered to particles, depending on the particles' origins. Particulate matter may be a primary contaminant, such as smoke emitted directly into the atmosphere, or a secondary contaminant formed by chemical reactions of gaseous contaminants in the air.

Particles larger than 10 microns are deposited in the human upper respiratory tract and are of less concern than particles equal to or less than 10 microns (PM₁₀) or particles equal to or less than 2.5 microns (PM_{2.5}). PM_{2.5} is considered the particulate size range of primary concern for human health impacts, and poses the greatest risk to human health because it can pass through the respiratory system deep within the lungs, leading to increased morbidity and mortality (FPWGAQ 1997).

For vehicles and equipment that burn diesel fuel, the diesel particulate emitted is a complex mixture of particles composed of porous elemental carbon, sulphate, nitrate, and a range of organic compounds that are adsorbed on the surface or within the solid particles. The major organic constituents are hydrocarbons, polycyclic aromatic hydrocarbons, and nitro-polyaromatic hydrocarbons. Typically, 90 per cent of these particles are less than 2.5 microns in diameter. A review by the California Air Resources Board of the literature on the health effects of diesel exhaust concluded that it is carcinogenic (ARB 1998).

Black carbon, present in diesel particulate, is the most strongly light-absorbing component of PM, absorbing solar radiation at all wavelengths. Formed as a product of incomplete fuel combustion, black carbon has a shorter residence time than greenhouse gases in the atmosphere. Since its potential radiative warming effects tend to be localized, any appropriate mitigation measures targeting black carbon can help reduce the rate of climate warming in the short term. Diesel PM also contains other components, such as sulphates, nitrates, and organic carbon, which generally reflect light and may therefore partially offset the climate warming effect of black carbon.

Road dust is made up of airborne particles that are generated by the friction of moving tires on roads. As with other particulate matter, road dust poses potential hazards to human health and the environment.

2.1.6 Volatile Organic Compounds

As defined by Environment Canada, VOCs are gaseous organic compounds, excluding those with negligible photochemical reactivity such as methane and other compounds. Volatile organic compounds are reactive in the atmosphere and can lead to increased formation of ground-level ozone through complex reactions with NO_x in the presence of sunlight. Volatile organic compounds arise from the incomplete combustion of a fuel.

2.1.7 Toxic Air Contaminants

In addition to CACs emitted from fossil-fuel burning vehicles, small amounts of TACs are released, including acetaldehyde, acrolein, benzene, benzo(a)pyrene, 1,3 butadiene, naphthalene, and formaldehyde. These substances are sometimes referred to as hazardous air pollutants, which are known or suspected to have harmful effects on human health and the environment.

2.2 Federal and Provincial Ambient Air Quality Objectives

In Canada, the federal and provincial governments have established ambient air quality objectives (AAQO) to ensure long-term protection of public health and the environment. In addition to these objectives, Metro Vancouver has created regionally focused ambient air quality objectives. Metro Vancouver has authorization to create and enforce air quality objectives within Metro Vancouver under the Environmental Management Act. Federally, up to three objective values have been recommended using the categories of maximum desirable, maximum acceptable, and maximum tolerable. The maximum desirable objective is the most stringent standard. British Columbia has established similar objective values, designated as levels A, B, and C for Carbon Monoxide (CO) while other pollutants have a single objective for a specified averaging period. Level A is the most stringent, and is typically applied to new and proposed discharges to the environment; it is usually the same as the federal maximum desirable objective. The federal and provincial objectives are summarized in **Table 1**.

Table 1 Federal and Provincial Ambient Air Quality Objectives

| Jurisdiction | Levels | Objective Description* |
|--------------|-------------------------------------|--|
| Federal | Maximum desirable (most stringent) | Long-term goal for air quality that provides a basis for an anti-degradation policy for unpolluted parts of the country and for continuing development of control technology. |
| | Maximum acceptable | Provides adequate protection against adverse effects on soil, water, vegetation, materials, animals, visibility, personal comfort and well-being. |
| | Maximum tolerable (least stringent) | Denotes time-based concentrations of air contaminants beyond which, due to a diminishing margin of safety, appropriate action is required without delay to protect the health of the general population. |
| Provincial | Level A (most stringent) | Refers to desirable goals for all discharges and/or to be applied to all new discharges and to existing installations whose discharges are significantly changed in quantity or quality. |
| | Level B | Refers to the acceptable intermediate objectives for all other discharges, to be reviewed periodically by the Director of Pollution Control. |
| | Level C (least stringent) | The immediate objective for all applicable existing industries to meet within a minimum technically feasible period of time. |

* Source: (B.C. MOE 2014, ECOLOG 2014).

3.0 Methods

The following general steps were followed to predict concentrations of the pollutants of concern:

1. Examine and analyze available ambient air quality, meteorological, and climate data.
2. Estimate the air contaminant emissions from vehicles for the three scenarios (existing 2011 conditions, and future (2031) conditions without, and with the Project).
3. Predict the effects of estimated emissions on ambient concentrations within the LSA using dispersion models.
4. Compare the predicted concentrations with applicable air quality objectives (e.g., federal, provincial and municipal)
5. Compare the estimated vehicle emissions for the existing and projected scenarios to emissions within the regional study area.

3.1 Air Quality, and Meteorological and Climate Data

Data from 2008 to 2012 were obtained from Metro Vancouver, which operates air quality monitoring stations for the region surrounding the Project area. Representative concentrations for the pollutants of concern were developed from the analyzed data. Data on toxic air contaminants (TACs) were obtained from the National Air Pollution Surveillance Network. Where available, meteorological data were also obtained from the Metro Vancouver sites, and from the Environment Canada station at Vancouver International Airport. **Table 2** lists the six ambient air quality monitoring stations from which data were used to characterize existing air quality in the vicinity of the Project area, and their coordinates.

Table 2 Ambient Air Quality Monitoring Stations and Parameters Measured

| Station ID | Station Name | Location Coordinates | Air Quality Parameters Measured | | | | | |
|------------|------------------|----------------------|---------------------------------|----|----------------|-----------------|-------------------|------------------|

3.2 Emissions Estimates

3.2.1 Parameters that Influence Emissions and Air Quality

The following parameters that are known to influence emissions from vehicle traffic were accounted for in estimating emissions related to the Project:

- Vehicle volume and distance travelled – The number of vehicles using the road and the distance they travel directly influence the quantity of contaminants emitted to the air. More vehicles mean more contaminant emissions, and the greater the distance travelled, the greater the volume of contaminants emitted.
- Vehicle speed – Depending on its speed, a vehicle will emit each of the contaminants of concern at varying rates. There is an optimum speed at which a vehicle will emit the least contaminants, but this speed is different for each vehicle and vehicle type. There is generally a range within which most vehicles are operating at their optimum performance and thus minimizing combustion emissions.
- Fleet profile – Vehicle types differ in the emissions they produce; therefore, the proportion of vehicles of each type in the fleet can change the emissions inventory. A road with a greater proportion of heavy trucks and/or bus traffic will have greater emissions of certain contaminants and less of others when compared to a road with a lower proportion of heavy vehicles.
- Vehicle fuel efficiency – Newer vehicles tend to have better fuel efficiency and lower emissions than older vehicles. Turnover of older vehicles for new ones in the fleet can change the emission inventory since less fuel is burned in new vehicles and therefore less combustion-related emissions are produced for the same distance travelled.
- Regulation and legislation – Government regulations such as vehicle fuel efficiency requirements, for example, catalytic converters, and fuel cleanliness (lower sulphur content) can change the vehicle emissions.

3.2.2 Vehicle Emissions

Vehicle emission factors were determined using the U.S. EPA MOVES modelling simulator (U.S. EPA 2012). At the core of the methodology is the emission equation:

$$\text{Emission (g)} = \text{activity data (VkmT)} \times \text{emission factor (g/VkmT)}$$

VkmT is the number of vehicle kilometres travelled. Emission calculations for vehicles are complex because of the many methods needed to determine reliable emission factors and activity data. Emission factors can vary significantly depending on:

- Vehicle type (e.g., light duty vs. heavy duty, gasoline vs. diesel)
- Mileage accumulation (age of vehicle)
- Speed (e.g., 20 km/h vs. 100 km/h)
- Control technology (e.g., catalytic converters)
- Other emission-reduction measures

The MOVES model generates emissions factors for highway motor vehicles and motorcycles fuelled by gasoline, diesel, and compressed natural gas (CNG). It also accounts for the effects on emissions caused by changes in vehicle emission standards; changes in vehicle populations and activity; and variation in local conditions such as temperature, humidity, pressure, and fuel quality.

The MOVES emission factors were generated by Sierra Research with support from Metro Vancouver. Although MOVES is a U.S.-based model, model input data from Metro Vancouver were used to ensure a good alignment between the Project and Metro Vancouver's regional mobile emission estimates and forecasts. These data included climate data, fleet age distribution, information on inspection and maintenance programs, and regulatory framework (e.g., renewable fuel requirement in B.C. of five per cent for gasoline and four per cent for diesel). Vancouver-specific data on fuel sales and fuel characteristics, such as Reid vapour pressure, ethanol blend market share, and biodiesel content were also used in the model to closely reflect conditions in the Project airshed.

Vehicle emission factors generated by MOVES take into account improvements in vehicle emission systems and technologies as newer technologies slowly penetrate the vehicle fleets and when newer vehicles with improved performance replace older ones. These vehicle technologies are mainly designed to improve fuel efficiency, reduce emissions, and improve the general safety of the driver.

The MOVES model generates emission factors for 13 types of vehicles, and for three distinct fuels (gasoline, diesel, and CNG), which are summarized, along with the existing 2011 and 2031 fleet profiles, in **Table 3**. The proportions of vehicle types (fleet profile) were also provided by Metro Vancouver, and as used in the *2010 Lower Fraser Valley Air Emissions Inventory and Forecast and Backcast* (Metro Vancouver 2013). Although Metro Vancouver's fleet profiles were developed for 2010 and 2030, they were deemed representative of the Project years of 2011 and 2031, and therefore adopted for use in this study.

As shown in **Table 3**, the fleet profile presents a very similar vehicle class breakdown in both 2011 and 2031. In 2011, light duty vehicles dominate the profile, accounting for 94.7 per cent of all vehicles, with 91.4 per cent being gasoline fuelled. Heavy duty trucks (motorhomes, refuse trucks, single and combination short- and long-haul trucks) account for 2.5 per cent, and buses account for 0.3 per cent of the fleet. Motorcycles account for the remaining 2.4 per cent. Electric vehicles account for 0.03 per cent (passenger cars and transit buses), whereas CNG buses only account for 0.003 per cent of the fleet.

Table 3 Fleet Profile for 2011 and 2031

| Description | | Percentage of Total Vehicles | |
|-----------------------------|------------------------------|------------------------------|--------|
| | | 2011 | 2031 |
| Gasoline | Motorcycle | 2.43 | 2.38 |
| | Passenger Car | 49.52 | 48.44 |
| | Passenger Truck | 31.35 | 30.68 |
| | Light Commercial Truck | 10.57 | 12.19 |
| | Transit Bus | 0.0001 | 0.0002 |
| | School Bus | 0.006 | 0.0045 |
| | Refuse Truck | 0.0003 | 0.0002 |
| | Single Unit Short-Haul Truck | 0.02 | 0.02 |
| | Single Unit Long-Haul Truck | 0.002 | 0.002 |
| | Motor Home | 0.60 | 0.59 |
| Diesel | Passenger Car | 0.72 | 0.72 |
| | Passenger Truck | 1.26 | 1.23 |
| | Light Commercial Truck | 1.31 | 1.51 |
| | Intercity Bus | 0.13 | 0.13 |
| | Transit Bus | 0.10 | 0.08 |
| | School Bus | 0.08 | 0.06 |
| | Refuse Truck | 0.05 | 0.04 |
| | Single Unit Short-Haul Truck | 0.65 | 0.62 |
| | Single Unit Long-Haul Truck | 0.06 | 0.07 |
| | Motor Home | 0.22 | 0.22 |
| | Combination Short-Haul Truck | 0.30 | 0.34 |
| Combination Long-Haul Truck | 0.57 | 0.63 | |
| CNG | Transit Bus | 0.003 | 0.005 |
| Elect | Passenger Car | 0.01 | 0.01 |
| | Transit Bus | 0.02 | 0.02 |

Emission factors for each vehicle type were provided by MOVES for a variety of vehicle speeds for the pollutants listed in **Table 4**. The MOVES-generated emission factors were subsequently multiplied by the traffic volumes to obtain the hourly, daily, and annual emissions for each Project road segment (described in **Section 6.6.5-1** and as follows):

- Segment 1: Bridgeport Road to Westminster Highway
- Segment 2: Westminster Highway to Steveston Highway
- Segment 3: Tunnel / new bridge and approach
- Segment 4: Highway 17A to Highway 17
- Segment 5: Highway 17 to Ladner Trunk Road
- Segment 6: Ladner Trunk Road to Highway 91

Table 4 Motor Vehicle Emissions Simulator Contaminant List

| Contaminants | |
|---|--|
| Volatile organic compounds | Primary PM _{2.5} - brake wear |
| Carbon monoxide | Primary PM _{2.5} - tire wear |
| Oxides of nitrogen | Methane |
| Sulfur dioxide | Nitrous oxide |
| Ammonia | Carbon dioxide |
| Primary PM ₁₀ - organic carbon | Benzene |
| Primary PM ₁₀ - elemental carbon | Naphthalene |
| Primary PM ₁₀ - sulfate particulate | 1,3-butadiene |
| Primary PM ₁₀ - brake wear | Formaldehyde |
| Primary PM ₁₀ - tire wear | Acetaldehyde |
| Primary PM _{2.5} - organic carbon | Acrolein |
| Primary PM _{2.5} - elemental carbon | Benzo(a)pyrene |
| Primary PM _{2.5} - sulfate particulate | |

Vehicle speed can also affect exhaust emissions. The emission rate in grams per kilometre (g/km) for many exhaust contaminants decreases with vehicle speed. The rate depends on the type of vehicle and engine technology.

Development of emission factors based on a variety of speeds allows for the simulation of free-flow and congested road conditions, which is a crucial factor when analyzing air quality conditions in the airshed. For this Project, different speeds were considered for each scenario and each road segment being assessed. While the speeds considered in each scenario are described in **Section 4.1**, **Table 5** and **Table 6** show a sample of CAC emission factors for different vehicle types travelling at a speed of 40 km/h, for the 2011 and 2031 scenarios respectively. Gasoline-fuelled vehicles — heavy duty vehicles in particular — have higher factors for CO, VOCs, NH₃, and SO₂ than other vehicle types. However, NO_x and particulate matter emission factors are highest for diesel heavy duty vehicles. Motorcycles have the highest emission factor for VOCs than any other vehicle type. In general, most emission factors are expected to decline between 2011 and 2031. In Table 5 and Table 6, the VOCs emission factors include exhaust and running evaporative emissions and the PM₁₀ and _{2.5} emission factors include exhaust and brake and tire wear emissions.

Table 5 Example of Emission Factors of CACs by Vehicle Type for 2011 (g/VkmT) for 40 km/h Speed

| 2011 Emission Factors (g/VkmT) | | | | | | | | |
|--------------------------------|------------------------------|--------|-------|-------|-----------------|-----------------|------------------|-------------------|
| Fuel Type | Vehicle Type | CO | NOx | VOCs | NH ₃ | SO ₂ | PM ₁₀ | PM _{2.5} |

3.2.2.1 Traffic Data

A range of future traffic scenarios in terms of tolling, traffic volumes, and congestion levels were considered, and the most conservative scenario was used in predicting future emissions. As discussed in **Section 5.1.2.4** of the Application, average annual daily traffic volumes (AADT) for 2030 were assessed using TransLink’s RTM for two scenarios– with the new bridge in place and no tolls being applied (TL-RTM Untolled), and with a new tolled bridge in place (TL-RTM Tolled). Given the variability in the forecasting, and to ensure a conservative assessment for EA purposes, the upper range of forecast values (TL-RTM untolled, 2030 With the Project) was used as it represents the highest potential volume of traffic

Forecasts of total traffic within the Project area for the years 2011 and 2031 with and without the Project were generated. The traffic numbers were subsequently broken down to the various MOVES vehicle types, based on Metro Vancouver’s fleet profiles. The traffic data and the emission factors from the MOVES model were used to determine the emission rates of the various contaminants for specific segments along the roadway. For each segment of road, the number of vehicles of each type and the associated emission factor were multiplied together to determine an emission rate per kilometre of road per vehicle. The dispersion model uses the emission rates, the road length, road width, and orientation, along with meteorological data, to predict ambient air quality resulting from traffic flowing on each road segment.

3.2.3 Road Dust

Road dust emissions are not generated as part of the MOVES model but were considered as part of the assessment. Therefore, road dust quantification followed the U.S. EPA methods described in *Compilation of Air Pollutant Emission Factors* (U.S. EPA 2011) AP-42, which deals with paved roads. According to AP-42 methods, road dust emissions are estimated using the following equation:

$$E = k \times (sL^{0.91}) \times (W^{1.02}) \times (1-P/4N)$$

where

k = particle size multiplier

sL = road surface silt loading

W = average weight of vehicles, the input of 1.9 tons was reused from 2005 Inventory

P = number of “wet” days with at least 0.254 mm precipitation

N = number of days in the period (1 year = 365 days)

The values for highway silt content and vehicle fleet average weight, as provided by Metro Vancouver, are 0.075 g/m² and 1.9 tonnes respectively. The data for number of wet days was collected from the meteorological station T17 for 2011 and totaled 147 days. The same values for silt loading, fleet weight, and wet days are considered for 2031. The resulting emission factors for road dust are as follows:

- PM = 0.53 g/VkmT
- PM₁₀ = 0.10 g/VkmT
- PM_{2.5} = 0.02 g/VkmT

The emission factors were applied to the total VkmT for the Project to estimate emissions from road dust. Road dust emissions were estimated to increase in direct proportion to the projected traffic volumes.

3.3 Air Quality Dispersion Modelling

Several models are available for air quality dispersion modelling, with each model offering different strengths and weaknesses. The selection of a model depends on several factors, the main ones being the types of sources, topography, accuracy required, and predictions of the parameters necessary to be assessed. The modelling approach used in this evaluation has been applied in other transportation-related projects in the Lower Mainland, and involves the use of a proven dispersion model for roadways, together with a reliable meteorological model for determining the winds near the Project area.

The *British Columbia Air Quality Modelling Guideline (B.C. Modelling Guideline)*, which outlines recommended steps (e.g. development of a conceptual as well as a detailed model plan) for completing modelling projects, was used to guide Project-related air-quality modelling. Metro Vancouver was involved in the model planning discussions from the early stages, and this consultation helped identify and address some of the issues noted in this assessment.

Predictions of ambient concentrations resulting from vehicle exhaust on highways in this and previous transportation-related assessments in B.C. employed the use of the CALINE3 (CALINE) model. Prior to the latest update of December 2015, the B.C. Modelling Guideline had included CALINE as a recommended model. As per Section 2.3.1 of the current version of the Modelling Guideline, CALINE would be considered an Alternate Model, as none of the Guideline-recommended models are specifically designed for traffic modelling.

CALINE is specifically designed for vehicle emissions from exhaust along roads. Other models such as CALPUFF, a Gaussian-Lagrangian puff dispersion model, or the Industrial Source Complex model (ISC3), a Gaussian plume model, can handle a variety of emission source

types, but do not currently have explicit algorithms to address road sources. The BC Ministry does not recommend any particular models for dispersion modelling of road sources (B.C. MOE 2015). The CAL3QHCR model is an alternative dispersion model for road sources which is focused on modelling of CO and queuing of vehicles at traffic lights. As CAL3QHCR utilizes the CALINE3 algorithms for traffic in motion, the CALINE3 model was deemed the most appropriate model selection for this assessment.

CALINE is the model currently recommended by the U.S. EPA for prediction of air quality impacts of roadway (line) emission sources. Because the CALINE model is U.S. EPA-approved, it has gone through rigorous evaluation to ensure that the model is providing conservative, yet accurate results. Due to CALINE's conservatism, its predicted concentrations tend to be higher than observed ambient air quality, but the model will provide a worst-case estimate of a project's effects on local air quality.

Traffic volumes are put into CALINE and are based on the results from the EMME/2 traffic model for the three traffic (2011 – Existing Roads, 2031 – Without Project, 2031 – With Project) scenarios considered. Emission factors were obtained from MOVES (described in **Section 3.2.2**). CALINE uses road segments to define the roadways in the model and includes emission factors (adjusted for various speed categories), traffic volumes, and the road alignment. The emission rates, in grams per mile per vehicle, were developed for each pollutant and each road segment.

Peak morning rush-hour traffic data were used to determine the maximum one-hour emission rates and in turn the one-hour predicted concentrations. For averaging periods longer than one hour, the annual average daily traffic was used to develop appropriate emission rates. The daily and annual average scenarios take into consideration changes in congestion throughout the course of a day and week that will contribute to changes in the amount of emitted pollutants.

CALINE predicts hourly ambient concentrations at designated receptor locations. Receptors are grid points in Universal Transverse Mercator (UTM) coordinates, where the computer model calculates predicted ambient concentrations. Receptors in this study were spaced at 100 m intervals along the roadway and extended perpendicular to and on either side of the road at intervals of 5, 10, 15, 20, 25, 50, 100, 250, 500 and 1,000 metres from the road (**Figure 1**). In addition to the gridded receptors (yellow dots on **Figure 1**), sensitive receptors such as schools, daycares, hospitals, and other sensitive areas were identified and included in the CALINE receptor grid (purple and pink shapes on **Figure 2**).

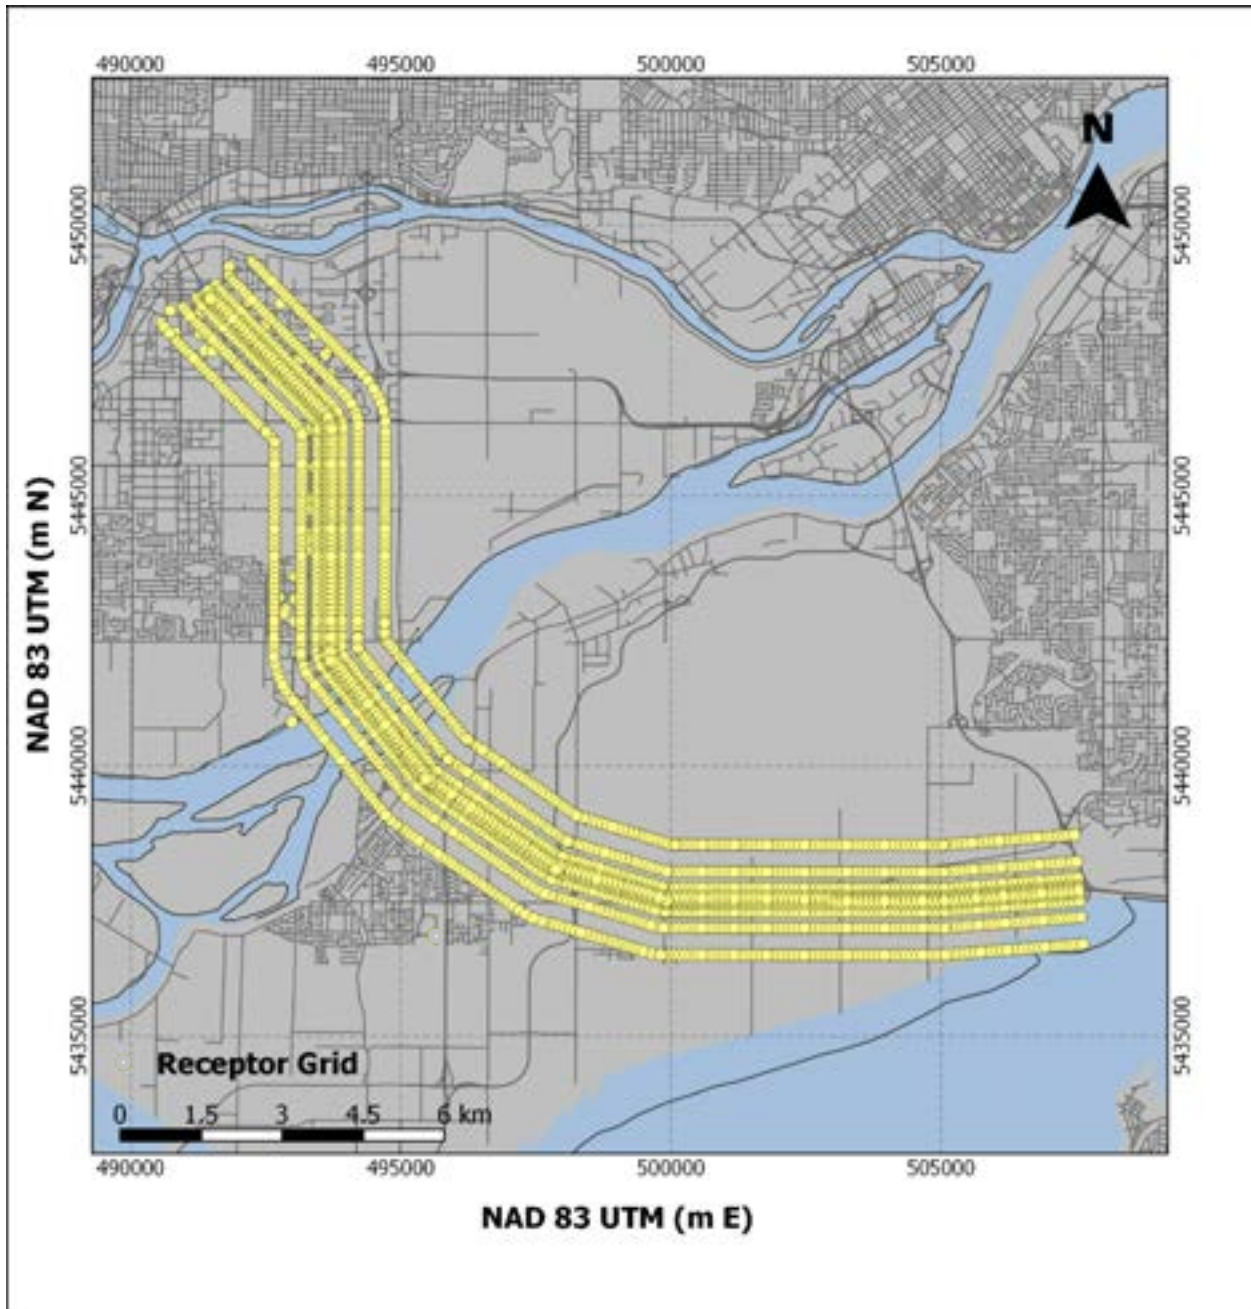

Figure 1 CALINE Receptor Grid

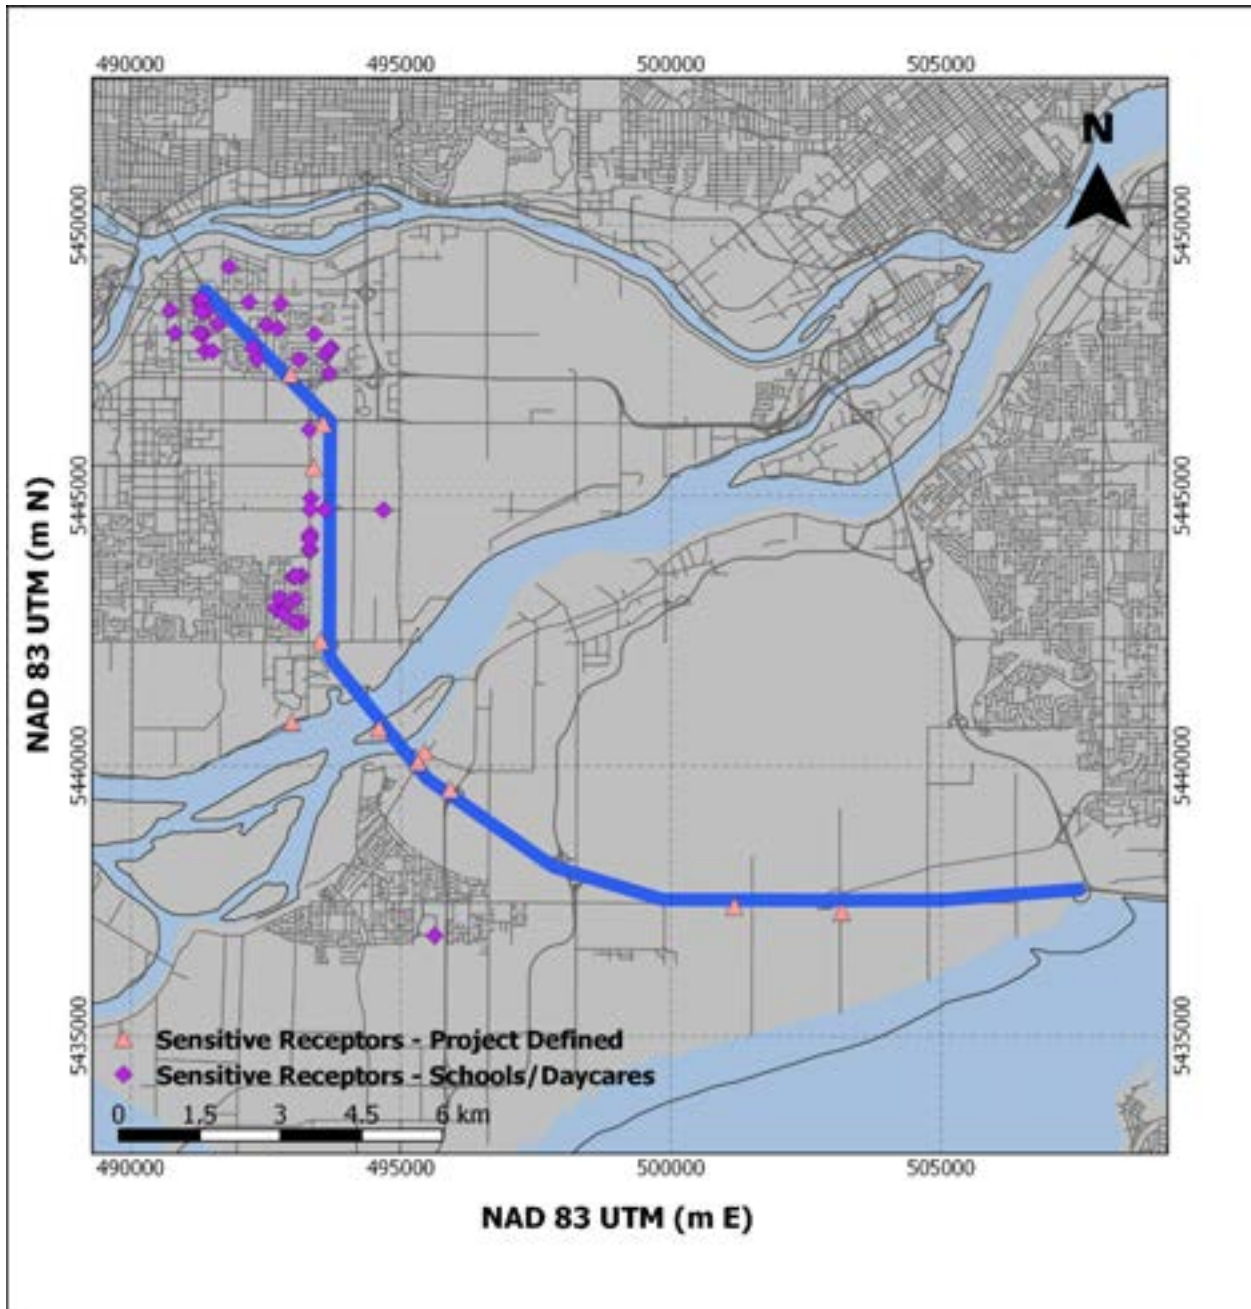

Figure 2 CALINE Sensitive Receptors Only

The CALMET model was used to provide an estimate of the wind fields (see **Section 3.3.1**, below). Meteorological data were extracted from CALMET for a location near the highway. The maximum predicted one-hour, 24-hour, and annual ambient concentrations of all modelled contaminants for traffic emissions were calculated at each receptor and are summarized, tabulated, and discussed in the sections below.

In addition to the maximum values, the maximum 98th percentile of the one-hour and 24-hour predicted ambient concentrations are also tabulated and discussed. The 98th percentile is the value for which ambient concentrations are equal to or less than, 98 per cent of the time. Therefore, if the one-hour 98th percentile for SO₂ concentrations is 8 µg/m³, ambient concentrations will be equal to or less than 8 µg/m³, 98 per cent of the time. The 98th percentile values are important to consider in addition to the maximum because the extreme maximum can often be an anomaly whereas the 98th percentile provides a better representation of maximum effects of the Project on local air quality. The air quality predictions were compared to the strictest applicable federal, provincial or regional (Metro Vancouver) air quality objectives.

3.3.1 Meteorological Data

The CALINE model requires input parameters of wind speed, wind direction, stability class, and mixing height to predict hourly contaminant concentrations. One year of data were extracted from the CALMET model output and used in the CALINE model. CALMET is a U.S. EPA-approved diagnostic meteorological computer model that generates three-dimensional fields of meteorological parameters based on surface and upper air meteorological data, digital land use data, and terrain data.

CALMET was used to characterize the meteorology near each modelled segment of the road for the period from January 1, 2012 to December 31, 2012. The model was run for the entire airshed at a 500 by 500 m grid resolution using a hybrid approach that integrates surface observations with prognostic model data. The surface observations were developed from the stations described in **Table 2**, while the prognostic data were generated from the Weather Research and Forecasting Non-hydrostatic Mesoscale Model, a state-of-the-science forecast model that was used to predict wind fields for the CALMET model. The CALMET model output was extracted at the spatial midpoint of the Project. For each modelled section, an hourly dataset representing one year of data was generated and formatted for input into the CALINE model.

Roughness length, a measurement of length that is used to indicate turbulence characteristics of a particular type of surface, is another parameter required by the model. For example, smooth plains where wind can blow without interference would have a very low roughness length (10 cm), while forested and urban areas with obstacles that can cause higher turbulence and have a longer roughness length. The roughness length for this study was presumed to be typical of an urban area (100 cm). Model results are presented in **Section 5.0**.

3.3.2 CALINE Model Geometry

The local study area extended from Bridgeport Road in Richmond to Highway 91 in Delta, and the EMME/2 traffic model divided the study area into the four road segments used by the CALINE model. For each segment that is modelled, CALINE requires:

- the beginning and end points of the segment (X and Y)
- traffic (number of vehicles per hour)
- emission rate (g/mile)
- whether the area is at grade (AG) or a bridge (BR) segment
- height (height of the bridge for bridge segments, and 0 m for at-grade segments; for the Project, the maximum allowed value of 10 m was used for the bridge segment)
- width of the road based on the existing road for the current and future-without-Project scenarios; for the future-with-Project scenario, incorporated increased lane widths

CALINE uses the UTM coordinates to determine the length and orientation of each segment. To account for dispersion of tailpipe emissions that occur in the turbulent wake behind a moving vehicle, three metres were added to either side of the road width, as recommended in the CALINE user guide (Benson 1979).

The use of the modelled bridge height option of 10 m, though in some cases less than the actual design height for the new bridge, allows the model to calculate the dispersion impact caused by air flowing under the bridge deck. Use of the lower height means the roadside concentrations are slightly higher than would be expected if a higher elevation was used. For modelling the existing Tunnel, the emissions that occurred within the Tunnel were distributed on an immediate segment at the entrance/exit on either side of the Tunnel.

For the two 2031 scenarios considered in this study (i.e., without and with the Project), an additional road segment was added to represent the two kilometres of the South Fraser Perimeter Road (SFPR)/Highway 17 that pass through the Project. Because SFPR was not operational until December, 2013, it was not considered in the 2011 scenario. The results presented in **Section 5** for the 2031 scenarios therefore account for the additional traffic resulting from SFPR.

3.3.3 Conversion for Oxides of Nitrogen

Vehicle emissions of NO_x are primarily in the form of NO (94 per cent) with very little NO₂ (six per cent) present. Since there are no existing objectives for ambient NO_x concentrations (the guidelines refer to NO₂), NO_x concentrations predicted by the model were converted to equivalent NO₂ concentrations using the Ambient Ratio Method (ARM). In accordance with the AQMG, if 100% NO_x conversion leads to exceedances of the AAQO, the Ambient Ratio (AR) method should be implemented to convert predicted NO_x concentrations into NO₂ concentrations. The AR method utilizes representative hourly NO_x and NO₂ monitoring data to characterize the NO₂/NO_x ratio given the ambient NO_x concentration. The method then applies this ratio to the model predicted NO_x emissions from the Project.

Ambient air quality data from Metro Vancouver station T18 (Burnaby South) was used to calculate the ratio of NO₂/NO_x. The resulting ratio was validated against NO₂/NO_x ratios and ambient air quality from Metro Vancouver stations T13 (North Delta) and T17 (Richmond South). For the 1-hour averaging period, an exponential equation of the form $y = ax^b$ was fit to the upper envelope of observed NO₂/NO_x versus NO_x, where a and b are empirically determined constants. The resulting equation was used to determine the ratio of NO₂/NO_x subject to the constraints that the equation is only valid for NO_x values where the corresponding NO₂/NO_x ratio is less than 1. **Figure 3** illustrates the dependence of NO₂/NO_x ratio on ambient NO_x air quality.

Figure 3 NO₂/NO_x Ratio versus 1-hour Average NO_x Observations from Metro Vancouver Station T18 (Burnaby South)

3.3.4 Ozone

Ground level O₃ is formed through a complex set of atmospheric chemical reactions with NO_x, and VOCs acting as key precursor species. Recent research on ground-level O₃ formation in the Lower Fraser Valley (LFV) (Steyn et al. 2011) revealed that, in the eastern portions of the valley from approximately Abbotsford to Hope, O₃ production is limited by the availability of NO_x; whereas, in western areas of the valley, from approximately Langley to the Georgia Strait, O₃ production is limited by the availability of VOCs. Both the relative amounts of available emissions and their locations affect the potential ground-level O₃ formation.

An estimate was made of potential changes in concentrations of ground-level O₃ based on changes in emissions of NO_x and VOCs. The methodology was based on a simplified model developed for the LFV by Steyn et al. (2011). The projected change in net O₃ concentrations was estimated using the slope of the potential change in O₃ concentration listed in **Table 7**. Modelling of peak ozone is a complex process involving many chemical reactions of various

pollutants and emissions. The US has developed the Community Mesoscale Air Quality Model (CMAQ), which could be used to model peak concentrations of ozone, however, there is no regulatory guidance on how the model should be used, and the possible error in prediction would be more significant than the potential changes in ozone that could be measured in the future.

Table 7 Ozone Concentrations in the Lower Fraser Valley and NOx/VOC Emission Changes

| Parameter | Units | 1985 | 2006 | Change | Slope | |
|---------------------|-------------------|------|------|--------|---|---|
| | | | | | VOC Limited Western LFV | NOx Limited Eastern LFV |
| VOC emissions | t/d | 439 | 296 | -143 | (µg/m ³ O ₃ / tonne per day VOC emission) | (µg/m ³ O ₃ / tonne per day NOx emission) |
| NOx emissions | t/d | 277 | 167 | -110 | | |
| Mean O ₃ | µg/m ³ | 55.4 | 42.2 | -13 | 0.09 | 0.12 |
| Peak O ₃ | µg/m ³ | 138 | 89 | -49 | 0.34 | 0.44 |

- Notes:**
1. Average daily emission rates (metric tonnes per day) within the LfV based on the Metro Vancouver emissions inventories (GVRD 2003, GVRD 2007 as cited in Steyn et al. 2011)
 2. Domain-wide overall ozone performance statistics for all WRF/CMAQ simulations and for the National Research Council (Smyth et al. 2006 as cited in Steyn et al. 2011) MM5/CMAQ 2001 simulation
 3. Table 53 Ozone performance statistics for daily peak ozone concentrations (Steyn et al. 2011)

3.3.5 Secondary Particulate Matter

Based on the overall reduction in emissions attributed to improvements in fleet performance (**Section 4.2.1**), it is anticipated that secondary particulate matter formation will decrease in the future with or without the Project. It should be noted that in locations with net NOx/VOC decreases, airborne radicals that formerly reacted with these compounds become free to react with SO₂, which can cause a small offsetting increase in sulphate aerosols (PM). However, sulphur emissions are also projected to decrease in the scenario of 2031 with the Project. Therefore, the result is expected to be a net reduction in secondary PM formation and is not considered further in this air quality evaluation.

3.3.6 Deposition

While vehicle emissions contribute to ambient air quality, they will eventually settle out of the atmosphere and deposit in areas surrounding the Project through sedimentation and precipitation processes. The CALINE model does not have the ability to model deposition, so the CALPUFF model, using the previously mentioned CALMET modelled data, was used for this purpose. CALPUFF is able to generate predicted wet and dry fluxes of pollutants.

Due to the computationally intensive nature of running CALPUFF, a sub-set of the road network was parameterized and run in the model that contained sensitive receptors, therefore representing a worst-case scenario. A 3.3 kilometer segment of Link 4 was chosen for parameterization in the CALPUFF model. Along this segment, 24 area sources were configured with a width of 14.4 meters and used the same emission factors, receptors and meteorology used in the CALINE model were used to model deposition and arrive at a predicted amount of deposition with distance from the side of the roadway. All other CALPUFF model parameters were set to default in accordance with the BC Air Quality Modelling Guideline.

For each of the three scenarios considered in the study, predicted maximum dry, wet, and total deposition were modelled for PM_{2.5}, PM₁₀, and total PM. The deposition modelling for the 2031 scenario with the Project predicts a maximum deposition of 4.56 g/m²/yr. **Table 8** presents dustfall deposition modelling results for the three scenarios in g/m²/yr.

Table 8 Maximum Predicted Deposition (g/m²/yr)

| Species | 2011 – Existing Roads | | | 2031 – Without Project | | | 2031 – With Project | | |
|-------------------|-----------------------|----------------|------------------|------------------------|----------------|------------------|---------------------|----------------|------------------|
| | Dry Deposition | Wet Deposition | Total Deposition | Dry Deposition | Wet Deposition | Total Deposition | Dry Deposition | Wet Deposition | Total Deposition |
| PM _{2.5} | 9.17E-04 | 4.07E-04 | 1.23E-03 | 9.47E-04 | 4.20E-04 | 1.27E-03 | 8.54E-04 | 4.15E-04 | 1.19E-03 |
| PM ₁₀ | 2.20E-01 | 6.29E-03 | 2.25E-01 | 2.68E-01 | 7.67E-03 | 2.74E-01 | 2.29E-01 | 7.50E-03 | 2.35E-01 |
| PM | 3.92E+00 | 4.56E-02 | 3.95E+00 | 5.09E+00 | 5.92E-02 | 5.13E+00 | 4.52E+00 | 5.46E-02 | 4.56E+00 |

3.4 Greenhouse Gases Evaluation

Greenhouse gases are contributors to the radiative warming effect of the environment that results in global climate change. The major GHGs include CO₂, CH₄ and N₂O, which are emitted from fuel combustion as well as other anthropogenic and natural sources. In addition, the warming effects of black carbon may be significant on a local geographic basis, especially on a shorter time scale¹.

In the context of GHG emissions generated in the Project alignment today, current congestion results in substantially more GHG emissions (CO₂-e) than would occur without such congestion. As illustrated in Table 8, the elimination of the one million vehicle delay hours, that occur annually due to existing congestion, would result in a reduction in CO₂-e emissions by existing traffic of more than 13,000 tonnes.

Table 9 Existing 2011 CO₂-e Emissions, with and without Congestion

| | 2011 Existing Roads | | |
|---|--|--|--------------------------------------|
| | Existing Emissions with Congestion (tonnes/yr) | Emissions without Congestion (tonnes/yr) | Change from Existing with Congestion |
| CO ₂ -e (20-year) ² | 163,157 | 149,774 | -13,383 (-8.2%) |

Considering future GHG emissions in the Project area, **Table 9** summarizes the comparison of emissions for the 2031 scenarios, with and without the Project. For the scenario without the Project, emission estimates have taken into account the effects of traffic congestion during rush hours on a weekday, as described in **Section 4.1**. Emissions for the 2011 existing scenario are also presented, to show the temporal reductions in GHG and black carbon emissions over time.

¹ As described in **Section 2.1.5**, black carbon is present in PM generated by fuel combustion processes, and absorbs solar radiation at all wavelengths. Given its shorter residence time in the atmosphere than GHGs, the use of the 100-year GWP factors to determine CO₂ equivalency may not be appropriate. Hence, published 20-year GWPs for GHGs and black carbon (Solomon et al. 2007, Minjares et al. 2014) were used to estimate the magnitude of the climate change effects of Project-related black carbon emission and its potential contribution to local climate change. Other components such as sulphates, nitrates, and organic carbon (OC) present in particulate matter generally reflect light and have a cooling effect that may partially offset the warming effect of black carbon.

² CO₂e (equivalent) emissions are based on the following respective weighting factors for 20-year and 100-year global warming potential per tonne of emission: CO₂ (1 and 1), CH₄ (72 and 25), N₂O (289 and 298), and black carbon (3,200 and 900).

Table 10 Forecast 2031 CO₂e Emissions, with and without Project (untolled)

| Pollutant | 2011 Existing Roads Emissions (tonnes/yr) | 2031 Emissions (tonnes/yr) | | Change from Without Project Scenario in 2031 |
|---|---|----------------------------|--------------|--|
| | | Without Project | With Project | |
| CO ₂ | 146,939 | 129,338 | 121,493 | -7,845 |
| CH ₄ | 12.2 | 15.0 | 15.1 | 0.1 |
| N ₂ O | 8.0 | 3.5 | 3.5 | 0 |
| Black carbon | 4.1 | 1.1 | 1.2 | 0.1 |
| CO ₂ -e (20-year) | 163,157 | 135,002 | 127,336 | -7,666 (-5.7%) |
| CO ₂ -e (100-year) | 153,287 | 131,753 | 123,973 | -7,780 (-5.9%) |
| Note: Because the new bridge will be tolled, CO ₂ -e reductions with the Project are projected to be greater than those noted above. | | | | |

As illustrated in **Table 10**, a substantial decrease in GHG emissions (CO₂e) on the Highway 99 corridor is forecast between 2011 and 2031, both with and without the Project,³ as newer engine technologies provide significant reductions in overall CO₂e emission levels.

Even if the Project did not include tolling, CO₂-e emissions in 2031 are forecast to decrease by 7,700 to 7,800 tonnes (5.7% to 5.9%) relative to without the Project. This net GHG reduction reflects savings due to congestion relief associated with Project improvements, which more than outweigh emissions associated with higher traffic volumes in an untolled scenario.

The 7,700 to 7,800 tonne annual reduction can be characterized as a “worst case” scenario, since it is based on the Highway 99 corridor being untolled. As the Project will be tolled, GHG reductions are projected to be greater due to the dampening effect on traffic volumes.

³ The only forecast increase in emissions, for CH₄, is due to the combination of increasing traffic and increasing frequency of diesel-engine vehicles, which are projected to outweigh the decrease in CH₄ emission rates for similar-engine vehicles. This CH₄ emissions trend is also observed in Metro Vancouver's 2010 emissions inventory and forecast (Metro Vancouver 2013).

4.0 Emission Estimate Results

4.1 Emission Quantification

To assess the effects of the Project on air quality, the three scenarios (existing 2011 conditions, and future (2031) conditions without, and with the Project) were modelled. In addition to the differences in traffic volumes and road layout among scenarios, speed also changes within each scenario depending on whether peak rush-hour traffic is considered or daily time scales. Vehicle emissions are directly related to vehicle speed and therefore must be considered. The traffic volumes considered in the different scenarios are summarized in **Table 11**.

The emission factors associated with peak traffic periods are a composite which consider 25% of the travel time at low speed to idling conditions and 75% of the time at 10 to 30 km/h. This emission factors were designed to simulate traffic under heavy congestion conditions and was used to estimate emissions for the following scenarios:

- Existing (2011) – peak period consisting of six hours of peak traffic per week day
- Future (2031) without the Project – peak period consisting of 10 hours of peak traffic per week day

Posted speeds were considered when modelling non-peak time periods for weekday and weekend days. Congestion conditions were applied to the Tunnel and adjacent roadway (Segment 3, in **Table 11**). Posted speeds were applied to the rest of the roadway upstream and downstream of the Tunnel as traffic is assumed to move through those sections without major congestion.

Table 11 Estimated Daily^a Traffic Volumes for Each Modelled Scenario

| Link # | Direction | Link Description | Existing Roads (2011) | Future (2031) Without Project | Future (2031) With Project |
|----------------|-------------|-------------------------------|-----------------------|-------------------------------|----------------------------|
| 1 | North Bound | Bridgeport to Westminster | 39,000 | 45,000 | 48,000 |
| 1 | South Bound | Bridgeport to Westminster | 36,500 | 39,500 | 42,000 |
| 2 | North Bound | Westminster to Steveston | 38,500 | 45,500 | 52,000 |
| 2 | South Bound | Westminster to Steveston | 37,000 | 46,500 | 55,000 |
| 3 ^b | North Bound | Tunnel/new Bridge | 41,000 | 47,500 | 53,500 |
| 3 ^a | South Bound | Tunnel/new Bridge | 41,000 | 51,500 | 61,000 |
| 4 | North Bound | Highway 17A to Highway 17 | 25,000 | 28,000 | 33,000 |
| 4 | South Bound | Highway 17A to Highway 17 | 26,000 | 38,500 | 43,000 |
| 5 | North Bound | Highway 17 to Ladner Trunk Rd | 25,000 | 31,000 | 31,500 |
| 5 | South Bound | Highway 17 to Ladner Trunk Rd | 26,000 | 36,500 | 40,500 |
| 6 | North Bound | Ladner Trunk to Highway 91 | 22,500 | 26,000 | 26,000 |
| 6 | South Bound | Ladner Trunk to Highway 91 | 24,500 | 34,000 | 37,500 |

Notes

^a Annual emissions are calculated by multiplying the emissions of a weekday by 261 plus by multiplying the emissions of a weekend by 104.

^b Average daily traffic volumes were not broken down by weekdays and weekend days. While volumes can be expected to be greater on weekdays than on weekend days, for the purposes of calculating vehicle emissions, daily volumes were assumed to be the same throughout the week. Thus although the traffic volumes are similar, the speeds considered during weekdays and weekend days were different.

As presented in **Table 11** congestion is expected to increase in 2031 if no alterations are considered to the existing network. When drivers are faced with long travelling delays, there is a tendency to find alternative routes. This results in a decrease in the expected number of vehicles travelling on that route and an increase of traffic volumes on alternative routes. However, in the case of the projected 2031 scenario with the new bridge, no congestion has been assumed. The configuration with the Project will not only maintain the regular route users, but will also divert additional traffic from other routes.

4.2 Vehicle Emissions

Vehicle-generated emissions of CACs and TACs for the 2031 scenarios with and without the Project are summarized in **Table 12**, which also shows the per cent emission changes that may occur in the future scenarios when compared with the 2011 estimates.

Table 12 Annual Emissions: Existing and Future with and without the Project

| Species | Emissions (tonnes/yr) | | | Change from 2011 (%) | | Difference between Future With and Without the Project (%) |
|-------------------------------|-----------------------|-----------------|--------------|----------------------|--------------|--|
| | Existing Roads | Without Project | With Project | Without Project | With Project | |
| | 2011 | 2031 | 2031 | | | |
| VOCs | 234.4 | 139.9 | 123.5 | -40% | -47% | -12% |
| CO | 3594.5 | 3216.5 | 3444.7 | -11% | -4% | 7% |
| NO _x | 388.4 | 166.1 | 169.6 | -57% | -56% | 2% |
| SO ₂ | 2.7 | 2.8 | 2.6 | 4% | -2% | -6% |
| NH ₃ | 11.8 | 9.8 | 9.6 | -17% | -19% | -2% |
| PM (Vehicles) | 14.9 | 12.8 | 9.4 | -14% | -37% | -27% |
| PM ₁₀ (Vehicles) | 14.9 | 12.8 | 9.4 | -14% | -37% | -27% |
| PM _{2.5} (Vehicles) | 11.0 | 7.2 | 6.3 | -35% | -42% | -11% |
| Diesel PM | 4.1 | 0.4 | 0.4 | -89% | -91% | -18% |
| PM (Road Dust) | 279.5 | 345.4 | 383.2 | 24% | 37% | 11% |
| PM ₁₀ (Road Dust) | 53.6 | 66.3 | 73.5 | 24% | 37% | 11% |
| PM _{2.5} (Road Dust) | 13.0 | 16.0 | 17.8 | 24% | 37% | 11% |
| Benzene | 7.8 | 4.1 | 4.2 | -47% | -47% | 1% |
| Naphthalene | 0.5 | 0.3 | 0.3 | -44% | -46% | -3% |
| 1,3-Butadiene | 0.8 | 0.4 | 0.4 | -49% | -46% | 5% |
| Formaldehyde | 2.8 | 1.7 | 1.7 | -37% | -40% | -5% |
| Acetaldehyde | 2.4 | 1.3 | 1.3 | -44% | -43% | 1% |
| Acrolein | 0.2 | 0.1 | 0.1 | -47% | -50% | -5% |
| Benzo(a)pyrene | 8.4E-04 | 5.7E-04 | 5.9E-04 | -33% | -31% | 3% |

Table 12 shows that, in general, the predicted emissions of most pollutants are lower in 2031 than in 2011. Although traffic in 2031 is projected to have increased by 23 per cent without the Project and 37 per cent with the Project (as described in Section 4.1 and shown in Table 9), reductions in emissions per vehicle by 2031 are large enough to offset increases in traffic volume. The reductions in per-vehicle emission by 2031 are due to the introduction of newer engine technologies in the vehicle fleet that provide better fuel efficiency.

Road dust and SO₂ are the two pollutants that are not projected to decrease by 2031. Road dust emissions are dependent only on VkmT, silt loading, vehicle fleet average weight, and precipitation days per year. Since all parameters are considered constant from 2011 to 2031, except for the VkmT, road dust emissions increase in direct proportion to VkmT growth as a result of increased traffic volume.

SO₂ emissions are highly dependent on fuel quality and consumption. Since there is no new fuel regulation being planned or implemented, the increase that occurs in SO₂ emissions in 2031 without the project is likely due to number of vehicles entering the fleet resulting in higher overall fuel consumption. Although the SO₂ emission factors show a slight decrease from 2011 to 2031, this decrease is not enough to offset the anticipated increase in traffic volumes and congestion in 2031 without the Project. The emissions of SO₂ are lower in 2031 with the Project than without the Project due to the lower levels of congestion expected with the new bridge.

Most pollutants, including TACs, show a declining emissions trend when comparing the 2031 scenario with Project to 2031 without the Project. The decrease in emissions is due to less congestion expected to occur in the road network with the Project. Overall, the reduction in emissions per vehicle is greater than the increase in emissions that would be anticipated to occur as a result of increases in traffic volumes. The only exceptions to this are the emissions of CO, NO_x, benzene, 1,3-butadiene, acetaldehyde and benzo(a)pyrene. The reduction of emissions per vehicle for these pollutants is not large enough to offset increases in traffic volume. Lastly, as mentioned previously, road dust emissions are only dependent on VkmT; therefore, the emissions are projected to increase linearly, in the 2031 with Project scenario, to the traffic growth in the absence of any other mitigating factors.

The declining emissions trend observed for road segment 3 (Tunnel) alone is much more significant when comparing the 2031 scenario with Project to 2031 without the Project. This trend is shown in **Table 13**. For the 2031 with Project scenario, all CAC pollutants associated with segment 3, with the exception of road dust, show a marked decline ranging from 56 per cent for VOC, 6 per cent for CO, 25 per cent for NO_x, 45 per cent for SO₂, 73 per cent for vehicle PM₁₀, 55 per cent for vehicle PM_{2.5} and 64 per cent for diesel PM. Similar trend is also

observed for TAC emissions. This pollutant declining trend is attributable to less congestion on this segment after the Tunnel is replaced with a new bridge. The increase in road dust shown in **Table 13** is primarily due to the increase in VkmT as discussed previously.

Table 13 Annual Emissions: Existing and Future with and without the Project for Road Segment 3 (Tunnel / new bridge and approach)

| Species | Emissions (tonnes/yr) | | | Change from 2011 (%) ¹ | | Difference between Future With and Without the Project (%) |
|-------------------------------|-----------------------|-----------------|--------------|-----------------------------------|--------------|--|
| | Existing Segment 3 | Without Project | With Project | Without Project | With Project | |
| | 2011 | 2031 | 2031 | | | |
| VOCs | 62.5 | 46.3 | 20.5 | -26% | -67% | -56% |
| CO | 683.7 | 604.6 | 570.8 | -12% | -17% | -6% |
| NOx | 78.1 | 37.5 | 28.1 | -52% | -64% | -25% |
| SO ₂ | 0.7 | 0.8 | 0.4 | 21% | -34% | -45% |
| NH ₃ | 2.7 | 2.5 | 1.6 | -5% | -40% | -37% |
| PM (Vehicles) | 4.8 | 5.7 | 1.6 | 18% | -68% | -73% |
| PM ₁₀ (Vehicles) | 4.8 | 5.7 | 1.6 | 18% | -68% | -73% |
| PM _{2.5} (Vehicles) | 2.9 | 2.3 | 1.1 | -20% | -64% | -55% |
| Diesel PM | 1.2 | 0.2 | 0.1 | -87% | -95% | -64% |
| PM (Road Dust) | 45.5 | 54.9 | 63.5 | 21% | 40% | 16% |
| PM ₁₀ (Road Dust) | 8.7 | 10.5 | 12.2 | 21% | 40% | 16% |
| PM _{2.5} (Road Dust) | 2.1 | 2.5 | 2.9 | 21% | 40% | 16% |
| Benzene | 1.7 | 1.0 | 0.7 | -42% | -58% | -28% |
| Naphthalene | 0.1 | 0.1 | 4.3E-02 | -37% | -62% | -40% |
| 1,3-Butadiene | 0.2 | 0.1 | 0.1 | -48% | -56% | -14% |
| Formaldehyde | 0.7 | 0.5 | 0.3 | -26% | -58% | -44% |
| Acetaldehyde | 0.5 | 0.3 | 0.2 | -39% | -56% | -28% |
| Acrolein | 4.0E-02 | 2.3E-02 | 1.3E-02 | -41% | -66% | -43% |
| Benzo(a)pyrene | 2.2E-04 | 1.2E-04 | 9.7E-05 | -44% | -55% | -21% |

Note: The emission numbers in columns 2, 3, and 4 have been rounded off to the tenth decimal place, and may not accurately reflect the percent change from 2011 as presented in this column.

5.0 Dispersion Modelling Results

5.1 Existing Air Quality

Ambient air quality evaluations provide an indication of the overall air quality within a localized area, rather than an analysis of specific emission sources. This type of an evaluation offers an insight into air quality within an area prior to the addition or modification of sources of air contaminants, such as the proposed modifications identified for the Project. The air quality evaluation can then be used to determine the capacity of the airshed to accept additional emission inputs while maintaining a desirable level of air quality.

5.1.1 Summary of Background Ambient Air Quality

The following are key results based on the data recorded at the monitoring stations:

- The measured CO concentrations are similar at T15, T18 and T31, while T39 records relatively low concentrations. Station T17 recorded the highest maximum one-hour concentration but was still well below the most stringent AAQO.
- The measured NO₂ concentrations were consistent across all monitoring stations.
- The measured ground level O₃ concentrations are similar at all locations. Each station recorded exceedances of the one-hour, 24-hour, and annual AAQO, while only T13, T15 and T17 exceeded the 8-hour average AAQO.
- The measured PM₁₀ concentrations were similar at the two locations that monitor for PM₁₀ (T18, T31).
- The measured one-hour PM_{2.5} concentrations vary across stations while the 24-hour and annual concentrations are consistent across stations. T13, T18, T31, and T39 all recorded exceedances of the most stringent 24-hour AAQO.
- The measured SO₂ concentrations at the four stations where SO₂ is recorded (T17, T18, T31 and T39) are similar.

Except where noted, the Metro Vancouver monitoring stations can be considered as representative of the air quality in the Project area, and they can be used to set a baseline air quality against which effects of the proposed Project can be measured.

Baseline values for CO, NO₂, PM₁₀, PM_{2.5}, and SO₂ were established from the ambient air quality data analysis using data from the Metro Vancouver network of monitoring stations. **Table 14** presents the background values that are used as a basis for assessing the potential impact of the Project's emissions on the local air quality. For the non-annual averaging periods, the maximum 98th percentile from the six stations and five years of data analyzed are used as the background. The annual baseline value is the average of the maximum annual average ambient concentrations across all six ambient air quality stations.

Table 14 Background Values for CO, NO₂, PM₁₀, PM_{2.5} and SO₂

| | CO | | | NO ₂ | | | PM _{2.5} | | PM ₁₀ | | SO ₂ | | |
|--------------------------------------|-------|-------|-------|-----------------|------|------|-------------------|-----|------------------|------|-----------------|------|-----|
| | 1-h | 8-h | Yr | 1-h | 24-h | Yr | 24-h | Yr | 24-h | Yr | 1-h | 24-h | Yr |
| Base-line Value (µg/m ³) | 1,271 | 1,116 | 287.6 | 75.2 | 62.3 | 24.6 | 14.6 | 4.4 | 28.9 | 12.8 | 9.9 | 7.0 | 2.0 |

Table 15 provides a summary of the background values for the available TACs, benzene, and 1,3-butadiene. The 24-hour value in both cases is the maximum recorded concentration during the period while the annual concentration is based on the maximum annual average from the Burnaby South National Air Pollution Surveillance monitoring station.

Table 15 Background Values for Toxic Air Contaminants

| | Benzene | | 1,3-butadiene | |
|-------------------------------------|---------|-------|---------------|------|
| | 24-h | Yr | 24-h | Yr |
| Baseline Value (µg/m ³) | 2.44 | 0.635 | 0.43 | 0.08 |

5.2 Results by Pollutant

Presented below are the predicted concentrations of CACs and TACs associated with Highway 99 traffic in the Project area. Each sub-section presents the results from the three traffic scenarios considered in this evaluation. For each pollutant, the most stringent ambient air quality objective is listed; bolded values indicate an exceedance of the applicable AAQO. For all pollutants except VOCs, predicted concentrations are presented for those averaging periods (i.e., 1-hour, 8-hour, 24-hour, or Annual) that have AAQO associated with them. There are no AAQOs for VOCs and formaldehyde; predicted concentrations of these compounds averaged over one hour, 24 hours, and one year are presented to facilitate a comparison of future conditions against current conditions.

5.2.1 Volatile Organic Compounds

Table 16 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for VOCs.

Table 16 Predicted Concentrations of Volatile Organic Compounds

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 2,796.7 | 1,167.9 | 1,832.2 | 764.2 | 393.5 | 134.4 | n/a |
| 24-hour | 256.3 | 162.2 | 193.7 | 123.1 | 49.4 | 32.9 | n/a |
| Annual | 73.4 | n/a | 55.8 | n/a | 13.8 | n/a | n/a |

Note: n/a = not applicable

There are no AAQOs for VOCs, but the 2011 existing scenario has the highest predicted concentrations of the three scenarios, while the 2031 scenario with the Project has the lowest predicted concentrations.

5.2.2 Carbon Monoxide

Table 17 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for CO.

Table 17 Predicted Concentrations of Carbon Monoxide

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 20,325.1 | 8,616.0 | 17,500.5 | 7,422.3 | 10,977.6 | 3,758.8 | 14,300 |
| 8-hour | 4,980.6 | 2,491.8 | 4,470.6 | 2,348.2 | 2,439.8 | 1,222.7 | 5,500 |

Note: Bolded values indicate exceedances of the relevant AAQO

For the existing scenario in 2011 and the 2031 without Project scenario, the maximum one-hour predicted concentration for CO exceeds the most stringent AAQO. None of the maximum 98th percentile 1-hour predications exceed the AAQO. The 2031 with Project 1-hour CO is 77 per cent of the most stringent objective of 14300 µg/m³. There are no exceedances of the most stringent eight-hour AAQO.

5.2.3 Nitrogen Dioxide

Table 18 and **Table 19** presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for NO₂. Modelled concentrations of NO_x were converted to NO₂ using 100% conversion (very conservative) and the Ambient Ratio Method method described in **Section 3.3.3**.

Table 18 Predicted Concentrations of Nitrogen Dioxide, 100% NO_x Conversion

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 2,574.1 | 1,086.0 | 1,252.4 | 526.0 | 539.7 | 184.0 | 188 |
| Annual | 92.8 | n/a | 45.4 | n/a | 18.6 | n/a | 40 |

Notes:
 Bolded values indicate exceedances of the relevant AAQO;
 n/a = not applicable

Table 19 Predicted Concentrations of Nitrogen Dioxide, ARM Conversion

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 115.6 | 104.1 | 105.9 | 96.0 | 96.3 | 87.3 | 188 |

Notes:
 Bolded values indicate exceedances of the relevant AAQO;
 n/a = not applicable

When NO_x is converted to NO₂ with the 100% conversion method, all three scenarios exceed the one-hour objective with the exception of the 1-hour 98th percentile for the 2031 with Project scenario. This is a very conservative approach as all emitted NO_x does not convert to NO₂. Applying the more refined ARM method of NO_x conversion, there are no exceedances of the 1-hour ambient air quality objectives. The ARM method is restricted to only 1-hour concentrations as there is not sufficient annual data to develop an ARM curve for annual concentrations.

Under ARM, the 2011 scenario is 61 per cent of the most stringent objective while the 2031 without project is 56 per cent of the objective. The 2031 with project is 51 per cent of the most stringent 1-hour objective.

5.2.4 Sulphur Dioxide

Table 20 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for SO₂.

Table 20 Predicted Concentrations of Sulphur Dioxide

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 27.6 | 11.6 | 29.9 | 12.5 | 8.3 | 2.8 | 196 |
| 24-hour | 2.7 | 1.7 | 3.3 | 2.2 | 1.0 | 0.7 | 125 |
| Annual | 0.8 | n/a | 1.0 | n/a | 0.3 | n/a | 25 |

Note: n/a = not applicable

No exceedances were predicted for SO₂ in any of the three scenarios modelled. For the existing scenario, the maximum predicted one-hour concentration is 14 per cent of the objective, while the maximum predicted 24-hour and annual concentrations are two and three per cent of their respective objectives. The 2031 scenario without the Project has a maximum predicted one-hour concentration that is 15 per cent of the most stringent AAQO. The maximum 24-hour and annual concentrations are three and four per cent of their respective objectives. The 2031 scenario with the Project has a maximum predicted one-hour concentration of four per cent of the one-hour objective, while the maximum predicted 24-hour concentration and annual concentration are one percent of the objective.

5.2.5 Ammonia

Table 21 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for NH₃.

Table 21 Predicted Concentrations of Ammonia

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 24-hour | 11.0 | 6.9 | 10.5 | 6.9 | 3.8 | 2.5 | 100 |

For each of the three scenarios modelled, there are no exceedances of the 24-hour objective for NH₃. The 2011 scenario has a maximum predicted 24-hour concentration, which is 11 per cent of the objective. For the 2031 without the Project, the maximum 24-hour predicted concentration is 10 per cent of the objective, while the 2031 with the Project is four per cent of the objective.

5.2.6 Fine Particulate Matter

Table 22 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for PM_{2.5}.

Table 22 Predicted Concentrations of Fine Particulate Matter

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 24-hour | 12.1 | 7.6 | 9.6 | 6.4 | 2.5 | 1.7 | 25 |
| Annual | 3.5 | n/a | 2.8 | n/a | 0.7 | n/a | 8 |

Note: n/a = not applicable

No exceedances were predicted for PM_{2.5} in any of the three scenarios modelled. For the existing scenario, the maximum predicted 24-hour concentration is 48 per cent of the objective. The maximum predicted annual average is 39 per cent for the 2031 without the Project and 10 per cent of the objective in the 2031 with Project scenario.

5.2.7 Inhalable Particulate Matter

Table 23 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for PM₁₀.

Table 23 Predicted Concentrations of Inhalable Particulate Matter

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 24-hour | 19.5 | 12.4 | 23.1 | 15.3 | 3.8 | 2.5 | 50 |
| Annual | 5.6 | n/a | 6.8 | n/a | 1.1 | n/a | 20 |

Note: n/a = not applicable

The predicted maximum 24-hour and annual concentrations for the 2011 existing scenario are under the most stringent AAQOs, and are 39 per cent and 28 per cent of the objectives, respectively. For the 2031 scenario without the Project, there are no predicted exceedances of the 24-hour or annual objective. The predicted maximum 24-hour concentration is 46 per cent of the most stringent objective, while the maximum predicted annual concentration is 34 per cent of the most stringent AAQO. With the Project operational in 2031, the maximum predicted 24-hour and maximum predicted annual concentrations are eight per cent and six per cent of the most stringent objectives, respectively.

5.2.8 Road Dust

Table 24 and Table 25 present the predicted maximum and maximum 98th percentile concentrations from the dispersion model for the PM₁₀ and PM_{2.5} component of road dust.

Table 24 Predicted Concentrations of Inhalable Particulate Matter from Road Dust

| Averaging Period | 2011 - Existing Roads | | 2031 - Without Project | | 2031 - With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 24-hour | 37.1 | 23.1 | 45.1 | 29.2 | 29.5 | 19.6 | 50 |
| Annual | 11.7 | n/a | 14.2 | n/a | 8.1 | n/a | 20 |

Note: n/a = not applicable

None of the scenarios are predicted to exceed the AAQOs.

The maximum predicted 24-hour average concentration for the 2011 existing scenario is 74 per cent of the most stringent AAQO, while the maximum predicted annual average concentration is 59 per cent of the objective. In the 2031 scenario without the Project, the maximum predicted 24-hour average concentration is 90 per cent of the objective. The maximum predicted annual average concentration is 71 per cent of the most stringent AAQO. For the operational phase of the Project in 2031, the maximum predicted 24-hour average concentration is 59 per cent of the objective, while the maximum predicted annual average concentration is 40 per cent of the objective.

Table 25 Predicted Concentrations of Inhalable Fine Particulate Matter from Road Dust

| Averaging Period | 2011 - Existing Roads | | 2031 - Without Project | | 2031 - With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 24-hour | 9.0 | 5.6 | 10.9 | 7.1 | 7.1 | 4.7 | 25 |
| Annual | 2.8 | n/a | 3.4 | n/a | 2.0 | n/a | 8 |

Note: n/a = not applicable

There are no predicted exceedances of the PM_{2.5} objectives for any of the three modelled scenarios. The maximum predicted 24-hour average concentration for the 2011 existing scenario is 36 per cent of the most stringent AAQO, while the maximum predicted annual average concentration is 35 per cent of the objective. In the 2031 scenario without the Project, the maximum predicted 24-hour average concentration is 44 per cent of the objective. The maximum predicted annual average concentration is 43 per cent of the most stringent AAQO. For the operational phase of the Project in 2031, the maximum predicted 24-hour average concentration is 28 per cent of the objective, while the maximum predicted annual average concentration is 24 per cent of the objective.

5.2.9 Benzene

Table 26 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for benzene.

Table 26 Predicted Concentrations of Benzene

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 58.0 | 24.4 | 32.4 | 13.6 | 13.3 | 4.5 | 30 |
| 24-hour | 6.9 | 4.3 | 4.0 | 2.6 | 1.7 | 1.1 | 2.3 |
| Annual | 2.0 | n/a | 1.2 | n/a | 0.5 | n/a | 0.45 |

Notes:
 Bolded values indicate exceedances of the relevant AAQO
 n/a = not applicable

For the existing scenario in 2011, the predicted maximum one-hour average concentration exceeds the AAQO, but the 98th percentile does not exceed the objective. The 24-hour and annual concentrations also exceed the AAQO. The 2031 scenario without the Project has exceedances for the maximum predicted 24-hour and annual averaging periods. The maximum predicted 98th percentile does not exceed the AAQO. In the 2031 with the Project operational, there are predicted exceedances for the annual objective only. The maximum predicted one-hour concentration is 44 per cent of the objective.

5.2.10 Naphthalene

Table 27 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for naphthalene.

Table 27 Predicted Concentrations of Naphthalene

| Averaging Period | 2011 - Existing Roads | | 2031 - Without Project | | 2031 - With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 24-hour | 0.5 | 0.3 | 0.3 | 0.2 | 0.1 | 0.1 | 22.5 |

For each of the three scenarios modelled, there are no exceedances of the 24-hour objective for naphthalene. The 2011 existing scenario has a maximum predicted 24-hour concentration that is two per cent of the objective. For the 2031 scenario without the Project, the maximum 24-hour predicted concentration one per cent of the objective, while the 2031 with the Project is less than one per cent of the objective.

5.2.11 1,3-butadiene

Table 28 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for 1,3-butadiene.

Table 28 Predicted Concentrations of 1,3-Butadiene

| Averaging Period | 2011 - Existing Roads | | 2031 - Without Project | | 2031 - With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 24-hour | 0.7 | 0.4 | 0.4 | 0.2 | 0.2 | 0.1 | 10 |
| Annual | 0.2 | n/a | 0.1 | n/a | 0.0 | 4.9E-02 | 2 |

Note: n/a = not applicable

The 24-hour average concentration is seven per cent of the most stringent AAQO, while the maximum predicted annual average concentration is 10 per cent of the objective. In the 2031 scenario without the Project, the maximum predicted 24-hour average concentration is four per cent of the objective. The maximum predicted annual average concentration is five per cent of the most stringent AAQO. For the 2031 scenario with the Project, both the maximum predicted 24-hour average concentration are two per cent of the objective.

5.2.12 Formaldehyde

Table 29 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for formaldehyde. There are no ambient air quality objectives available for formaldehyde.

Table 29 Predicted Concentrations of Formaldehyde

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 26.3 | 11.0 | 18.1 | 7.6 | 0.8 | 0.3 | 60 |

Note: n/a = not applicable

There are no exceedances of the BC Action air quality objective for formaldehyde on the 1-hour averaging period. The 2011 scenario maximum concentration is 44 per cent of the objective. The 2031 without Project scenario and the 2031 with Project scenario are 30 per cent and 1 per cent of the objective, respectively.

5.2.13 Acetaldehyde

Table 30 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for acetaldehyde.

Table 30 Predicted Concentrations of Acetaldehyde

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 18.1 | 7.6 | 10.5 | 4.4 | 4.3 | 1.5 | 90 |
| 24-hour | 2.1 | 1.3 | 1.3 | 0.9 | 0.5 | 0.4 | 500 |

No exceedances were predicted for acetaldehyde in any of the three scenarios modelled. For the existing scenario, the maximum predicted one-hour concentration is 20 per cent of the objective, while the maximum predicted 24-hour is less than one per cent of the objective. The 2031 scenario without the Project has a maximum predicted one-hour concentration that is 12 per cent of the most stringent AAQO. The maximum 24-hour is less than one per cent of the objective. The 2031 scenario with the Project has a maximum predicted one-hour concentration that is five per cent of the one-hour objective, while the maximum predicted 24-hour concentration is less than one per cent of the objective.

5.2.14 Acrolein

Table 31 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for acrolein.

Table 31 Predicted Concentrations of Acrolein

| Averaging Period | 2011 - Existing Roads | | 2031 – Without Project | | 2031 – With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 1-hour | 1.7 | 0.7 | 0.9 | 0.4 | 0.3 | 0.1 | 4.5 |
| 24-hour | 0.2 | 0.1 | 0.1 | 0.1 | 3.2E-02 | 2.1E-02 | 0.4 |

No exceedances were predicted for acrolein in any of the three scenarios modelled. For the existing scenario, the maximum predicted one-hour concentration is 37 per cent of the objective, while the maximum predicted 24-hour concentration is 41 per cent of the objective. The 2031 scenario without the Project has a maximum predicted one-hour concentration that is 19 per cent of the most stringent AAQO. The maximum 24-hour concentration is 24 per cent of the objective. The 2031 scenario with the Project has a maximum predicted one-hour concentration of six per cent of the one-hour objective, while the maximum predicted 24-hour is 8 per cent of the objective.

5.2.15 Benzo(a)pyrene

Table 32 presents the predicted maximum and maximum 98th percentile concentrations from the dispersion model for benzo(a)pyrene. For all three scenarios, the predicted maximum 24-hour and annual concentrations exceed the AAQO.

Table 32 Predicted Concentrations of Benzo(a)pyrene

| Averaging Period | 2011 - Existing Roads | | 2031 - Without Project | | 2031 - With Project | | Ambient Air Quality Objective |
|------------------|-----------------------|-----------------------------|------------------------|-----------------------------|---------------------|-----------------------------|-------------------------------|
| | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | Maximum Predicted | 98 th Percentile | |
| 24-hour | 8.9E-04 | 5.7E-04 | 5.1E-04 | 3.3E-04 | 2.3E-04 | 1.6E-04 | 5.00E-05 |
| Annual | 2.6E-04 | n/a | 1.5E-04 | n/a | 6.4E-05 | n/a | 1.00E-05 |

Notes:

Bolded values indicate exceedances of the relevant AAQO

n/a = not applicable

5.2.16 Ozone

Estimations of the change in O₃ concentrations are summarized for 2031 with and without the Project are summarized in **Table 33** (Steyn et al. 2011). The analysis suggests that in the western portion of the LFV, which is VOC-limited, a reduction in NO_x and VOC emissions without the Project would result in a very slight increase (less than 0.1 µg/m³) in O₃ concentrations in 2031 compared with 2011 existing concentrations. A reduction in NO_x and VOC emissions with the Project would result in a very slight increase (less than 0.1 µg/m³) in O₃ concentrations in 2031 compared with 2011 existing concentrations. When comparing 2031 with and without the Project, the change in NO_x and VOC emissions is so small that there is a negligible difference in expected O₃ concentrations.

Overall, the change in O₃ concentrations is negligible, with a worst-case estimate of a peak change of less than 0.1 µg/m³ in 24-hour average concentrations. These changes in ground-level O₃ are considered to be negligible because they fall within the range of accuracy of O₃ sampling equipment (i.e., ±1 ppb or ±2 µg/m³). Therefore, the change in O₃ levels, with or without the Project, would fall within the noise levels of O₃ monitoring equipment, resulting in no measurable change in O₃ levels in the LFV.

Table 33 Predicted Maximum Concentrations (µg/m³) for Ozone

| Criteria | 100 µg/m ³ | 121.6 µg/m ³ | 30 µg/m ³ | 30 µg/m ³ |
|-----------------------------------|---|-------------------------|----------------------|----------------------|
| | O ₃ Concentration, µg/m ³ | | | |
| Emissions Scenario | 1 h | 8 h | 24 h | Annual |
| 2011 O ₃ concentration | 88.7 | 84.7 | 81.6 | 47.2 |
| 2031 without the Project | 88.7 | 84.7 | 81.6 | 47.2 |
| 2031 with the Project | 88.7 | 84.7 | 81.6 | 47.2 |

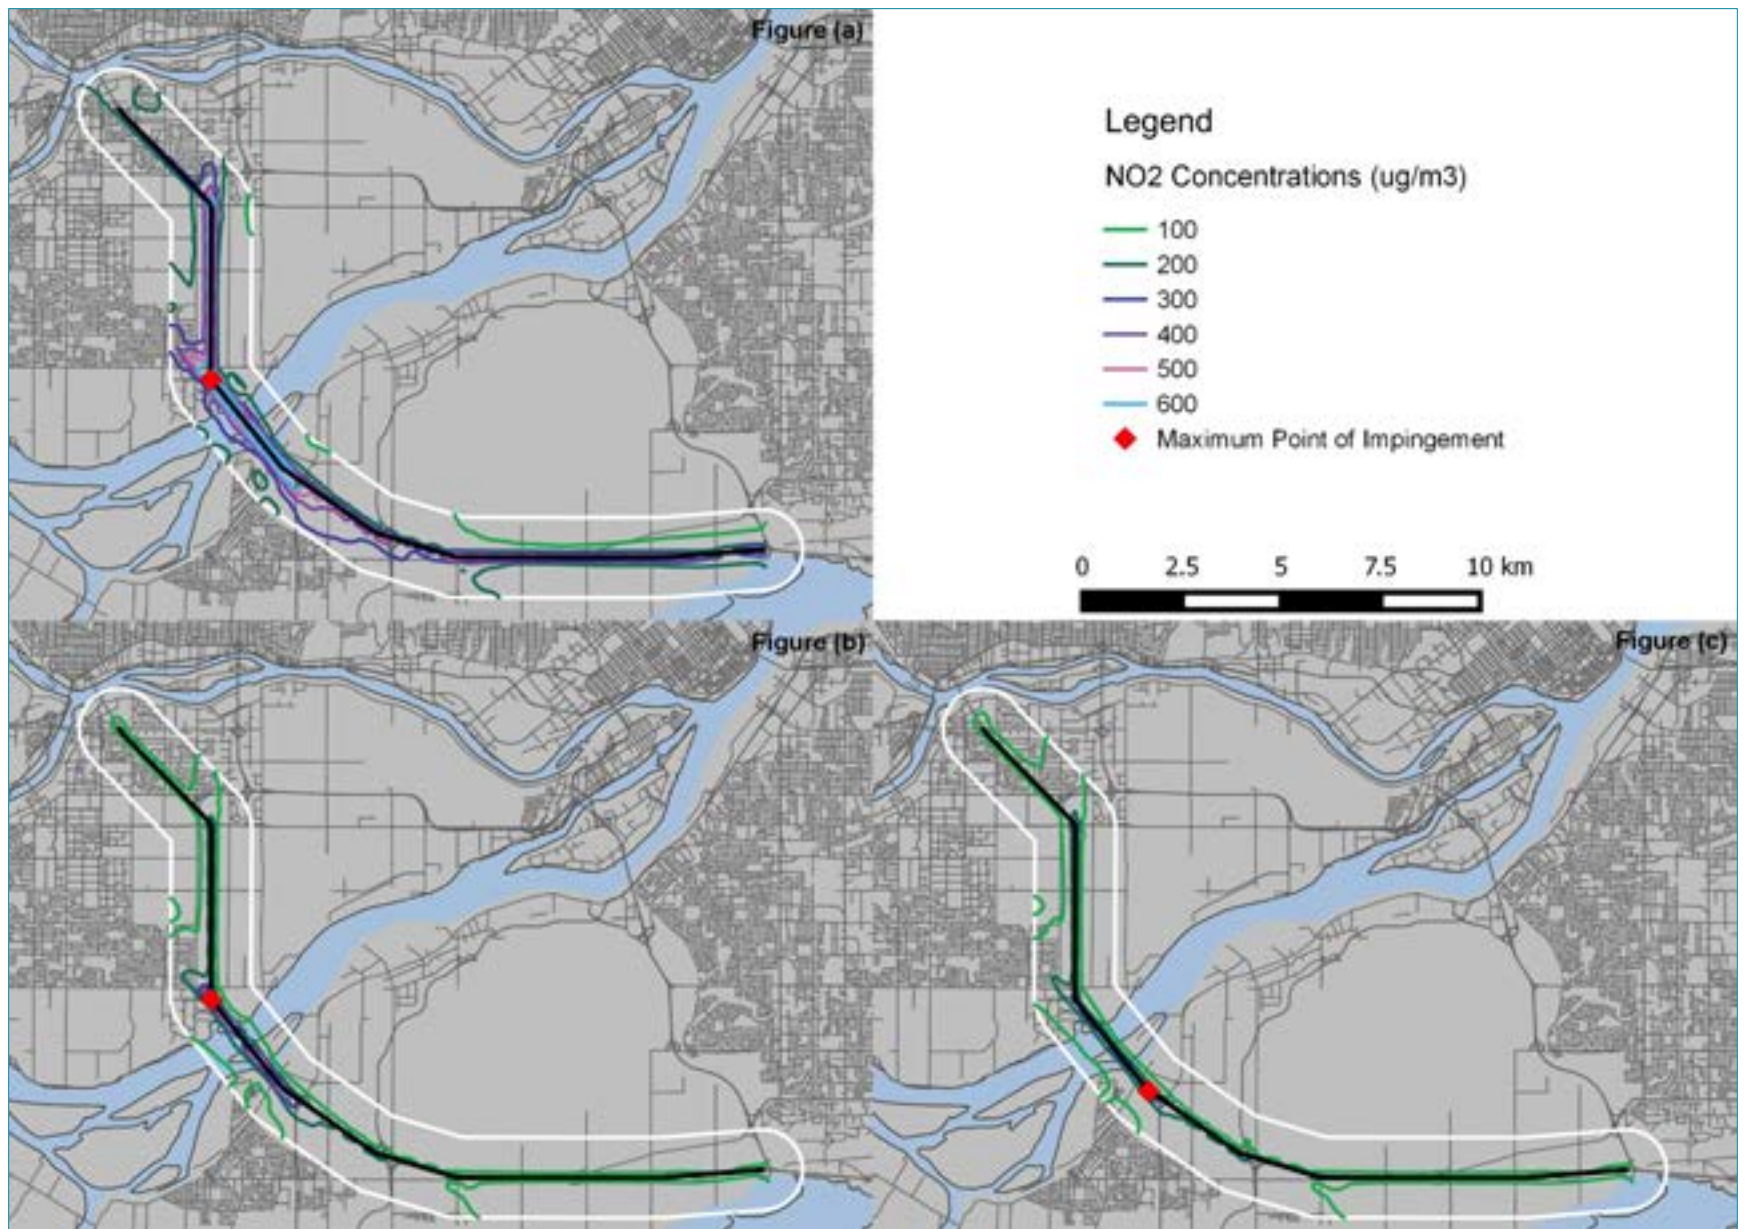

5.3 Spatial Variability of Predicted Concentrations

In the previous sections, tabular results were presented for the maximum predicted concentration for each pollutant under each of the three scenarios (**Table 16** to **Table 32**). The tabular results demonstrate the worst-case predictions at specific locations; however, to illustrate the spatial variability associated with dispersion, contour plots for NO₂ are presented in this section (**Figure 4** to **Figure 6**). These contour plots illustrate the decrease in concentration as a function of distance from the roadway. The contour plots clearly show that the highest concentrations are located in areas where there are a high number of vehicles, and that predicted concentrations are related to the distance from the road, with the highest values being recorded by the receptors that are five to 15 m from the road edge.

For the current scenario and the 2031 scenario without the Project, there are areas of higher concentrations located at the either entrance to the Tunnel. The 2031 scenario with the Project shows higher concentrations near at the southern end of the bridge, near Highway 17A.

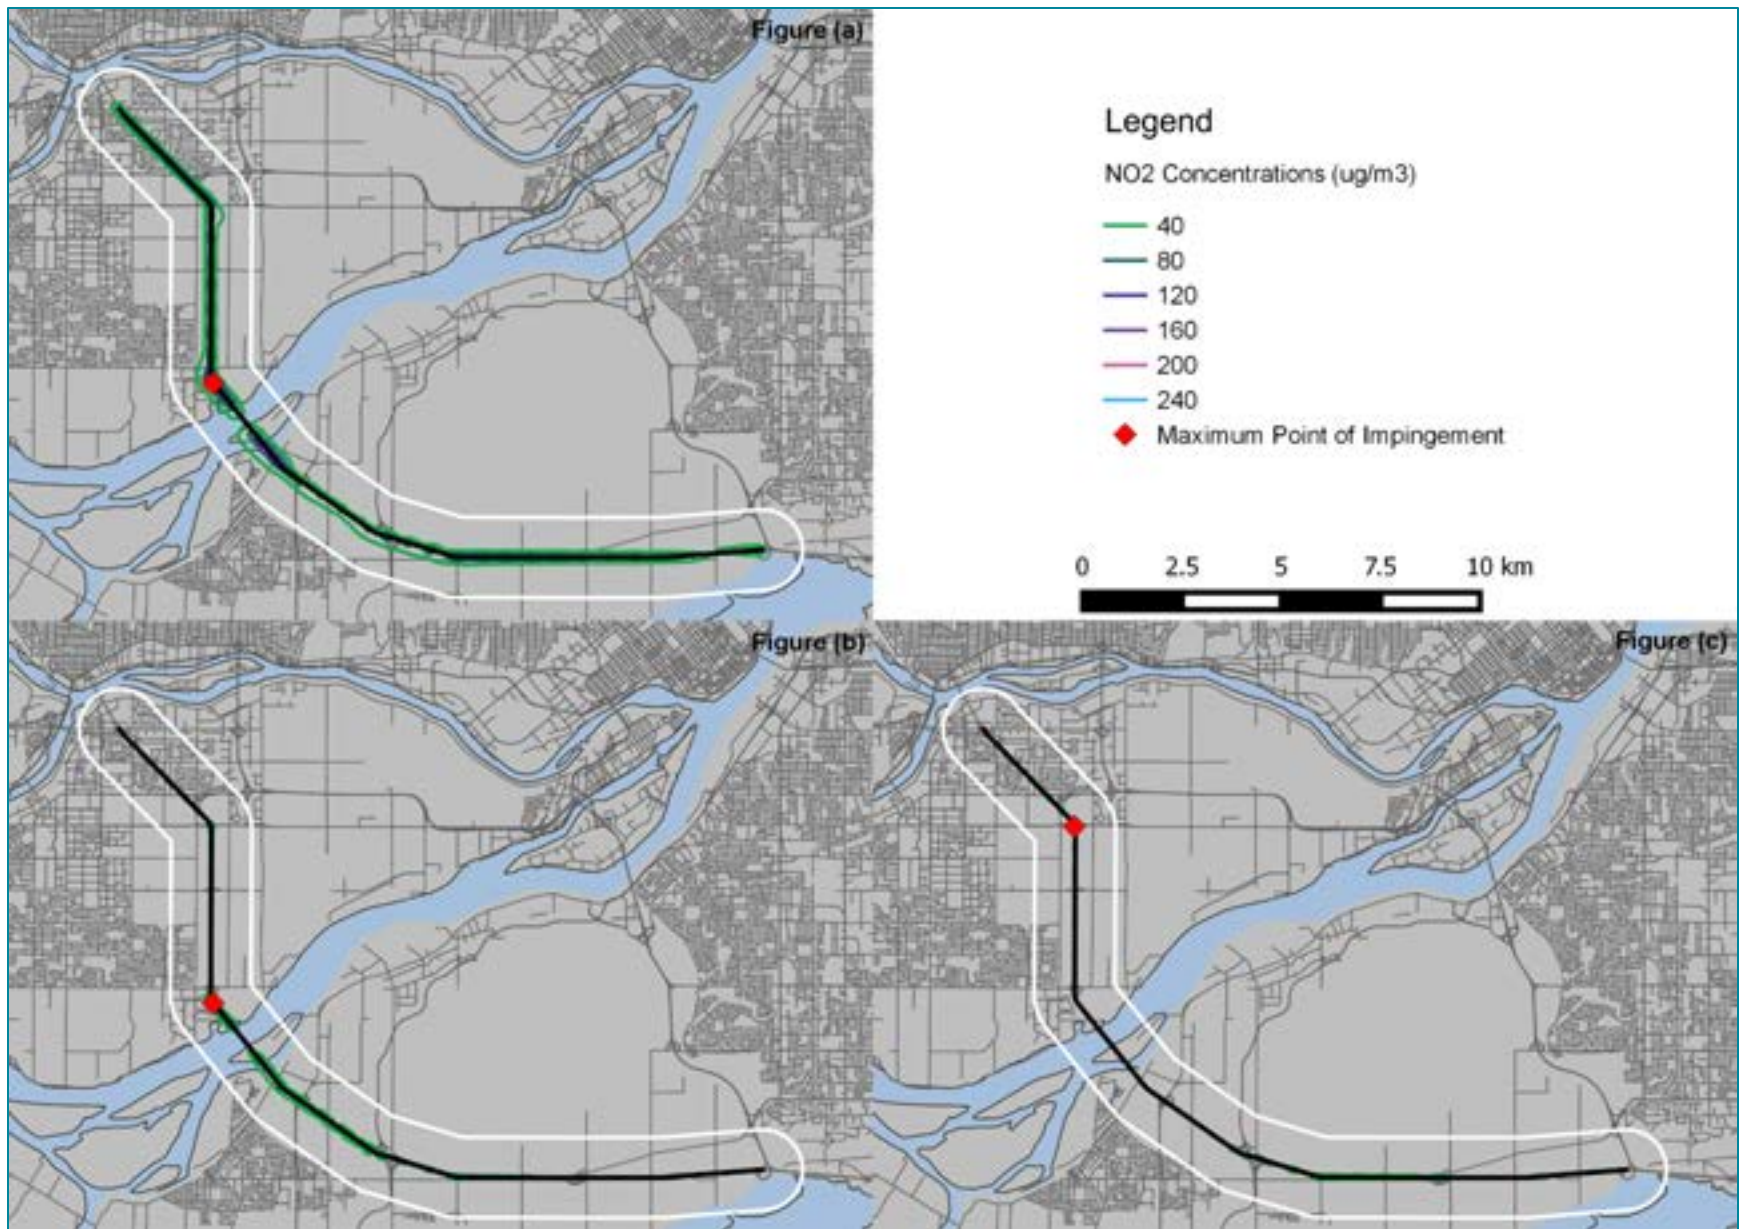

The locations of the maximum predicted values for one-hour, 24-hour, and annual averaging periods are also shown on **Figure 4** to **Figure 6**. While the figures present the maximum values for NO_x, other pollutants exhibit similar patterns. Generally, in 2011 and 2031 without the project, concentrations are near the entrance to the Tunnel for all three averaging periods. Concentrations tend to decrease away from the road.

For the 2031 scenario with the Project, the maximum one-hour emission is located near the south side of the new bridge. Peak one-hour traffic is significantly higher on the new bridge than through the Tunnel, which likely contributes to the maximum one-hour emission occurring near the new bridge approaches. The 24-hour and annual averaging periods predict the maximum emission occur near Westminster Highway due to the increased traffic along that link. Because, for the purposes of this study, the new bridge has been modelled at a constant height of 10 m, this increases the dispersion that occurs before the plume reaches a receptor. This, along with the increase vehicle traffic, leads to the maximum 24-hour and annual concentration predictions to occur on near Westminster Highway and not on the new bridge.

5.4 Summary

Table 34 shows predicted maximum concentrations of Highway 99-related emissions of key pollutants, based on dispersion modelling results. Of the three scenarios, the 2031 scenario with the Project has the lowest predicted maximum concentrations for all pollutants and averaging periods. While more vehicle traffic is predicted to use the road due to increased capacity, improvements in fleet technology, combined with a higher average travel speed and improved dispersion of pollutants, is expected to lead to reduced ambient concentrations, especially for 1-hour concentrations, in the study area.

Table 34 Summary of Maximum Predicted Highway 99-related Emission Concentrations

| Pollutant | Averaging Period | 2011 Existing ($\mu\text{g}/\text{m}^3$) | 2031 Without Project ($\mu\text{g}/\text{m}^3$) | 2031 With Project ($\mu\text{g}/\text{m}^3$) |
|-----------------------------------|------------------|--|---|--|
| CO | 1-hour | 20,325.1 | 17,500.5 | 10,977.6 |
| | 8-hour | 4,980.60 | 4,470.60 | 2,439.78 |
| NO ₂ (100% conversion) | 1-hour | 2,574.1 | 1,252.4 | 539.7 |
| | 24-hour | 327.2 | 157.1 | 67.8 |
| | Annual | 92.8 | 45.4 | 18.6 |
| SO ₂ | 1-hour | 27.6 | 29.9 | 8.3 |
| | 24-hour | 2.7 | 3.3 | 1.0 |
| | Annual | 0.8 | 1.0 | 0.3 |
| PM ₁₀ (vehicles) | 24-hour | 19.5 | 23.1 | 3.8 |
| | Annual | 5.6 | 6.8 | 1.1 |
| PM ₁₀ (road dust) | 24-hour | 37.1 | 45.1 | 29.5 |
| | Annual | 11.7 | 14.2 | 8.1 |
| Total PM ₁₀ | 24-hour | 56.7 | 68.2 | 33.2 |
| | Annual | 17.4 | 21.1 | 9.2 |
| PM _{2.5} (vehicles) | 24-hour | 12.1 | 9.6 | 2.5 |
| | Annual | 3.5 | 2.8 | 0.7 |
| PM _{2.5} (road dust) | 24-hour | 9.0 | 10.9 | 7.1 |
| | Annual | 2.8 | 3.4 | 2.0 |

| | Annual | 0.2 | 0.1 | 0.0 |

6.0 Regional Air Quality Evaluation

6.1 Regional Emissions

This section discusses the potential effects of the proposed Project on regional air quality in 2031. Consideration is given to Project-related air emissions, as well future changes in regional emissions that may occur as a result of other transportation projects or changes in regulatory policies and programs, including those outlined in Section 6.2. Forecast 2031 LFV emissions include projected emissions from these other transportation projects (Hou, personal communication, 2014) (Table 35). On a regional level, the Project pollutant emission contributions compared to the total forecast vehicle emissions in the LFV airshed are very small.

Table 35 Contribution of Project Emissions to the Lower Fraser Valley Vehicle Emissions

| Pollutant | 2031 Emissions (tonnes/yr) | | Proportion of 2031 with Project to Overall LFV Vehicle Emissions (%) |
|-------------------------------|----------------------------|-----------------------|--|
| | With Project | LFV Vehicle Emissions | |
| VOCs | 123.5 | 6,514.0 | 2% |
| CO | 3444.7 | 131,461.1 | 3% |
| NOx | 169.6 | 9,167.1 | 2% |
| SO ₂ | 2.6 | 56.7 | 5% |
| NH ₃ | 9.6 | 436.9 | 2% |
| PM (vehicles) | 9.4 | 332.2 | 3% |
| PM ₁₀ (vehicles) | 9.4 | 332.2 | 1% |
| PM _{2.5} (vehicles) | 6.3 | 307.7 | 3% |
| PM (road dust) | 383.2 | 38,559.6 | 1% |
| PM ₁₀ (road dust) | 73.5 | 7,400.5 | 2% |
| PM _{2.5} (road dust) | 17.8 | 1,794.6 | 1% |
| Benzene | 4.2 | - | - |
| Naphthalene | 0.3 | - | - |
| 1,3-butadiene | 0.4 | - | - |
| Formaldehyde | 1.7 | - | - |
| Acetaldehyde | 1.3 | - | - |
| Acrolein | 0.1 | - | - |
| Benzo(a)pyrene | 5.9E-04 | - | - |

Notes: "-" = Information not available

Total estimated emissions of CACs from traffic in the 2031 scenario with the Project are between one and five per cent of the LFV total vehicle emissions. It is projected that, traffic being diverted from other routes (e.g., the Alex Fraser Bridge) will result in an additional reduction to emissions in the region due to the ease of traffic congestion. This anticipated decline in emissions represents a beneficial effect of the Project in the context of regional air quality, with forecast LFV emissions projected to be slightly lower than forecasted without the Project in full operation.

As discussed in **Section 4.1.1**, most pollutants show a declining emissions trend when comparing the 2031 with Project to the without Project scenario. This decrease in emissions, resulting from less congestion in the road network following the implementation of the Project, helps to further reduce the originally estimated 2031 LFV emission forecast prepared by Metro Vancouver.

6.2 Regional Air Quality

While it is not feasible to contemplate all projects and changes that may occur in the future, Metro Vancouver's emissions inventory does incorporate reasonable assumptions as to what future emissions will be, based on foreseeable changes within the LFV. Forecasted policy measures and new emission sources quantified in the inventory include Metro Vancouver Permit changes, a new waste-to-energy facility, and the Metro Vancouver Boiler and Heater Regulation (Metro Vancouver 2013).

Other reasonably foreseeable industrial projects that would result in emissions were also reviewed; none were considered to result in volumes of air emissions that might substantially influence local air quality. Those projects that could influence vehicle emissions are addressed within the context of the traffic modelling that incorporates certain land-use and marine activities. It was therefore assumed that modelling predicted concentrations, based on emissions in 2031 with the Project, when added to the existing background concentrations to account for contributions from all other sources, would appropriately describe potential effects of the Project on future regional air quality.

While some emissions are anticipated to remain steady, or to increase slightly in the future, conservative background concentration values were assumed to account as a reasonable surrogate for the contribution of those emissions, should there be additional emissions contributing to the ambient air quality in the vicinity of the Project in the future.

Table 36 provides an overview of regional air quality in 2031 with and without the Project in terms of maximum overall pollutant concentrations—i.e. predicted maximum Project-related emission concentrations plus background concentrations. Bolded values indicate an exceedance of the most stringent AAQO. Overall ambient concentrations of all pollutants in the region are predicted to be lower for the 2031 scenario with the Project when compared to the scenario without the Project in 2031.

Table 36 Predicted Regional Air Quality With and Without the Project in 2031

| Pollutant | Averaging Period | Background Concentration ($\mu\text{g}/\text{m}^3$) | Overall Concentration in 2031 without Project ($\mu\text{g}/\text{m}^3$) | Overall Concentration in 2031 with Project ($\mu\text{g}/\text{m}^3$) | Most Stringent AAQO ($\mu\text{g}/\text{m}^3$) |
|-------------------------|------------------|---|--|---|--|
| CO | 1-hour | 1271 | 18,771.5 | 12,248.6 | 14,300 |
| | 8-hour | 1,116 | 5,586.6 | 3,555.8 | 5,500 |
| NO ₂ (ARM) | 1-hour | - | 105.9 | 96.3 | 188 |
| | Annual | 25 | 70.4 | 43.6 | 40 |
| SO ₂ | 1-hour | 10 | 39.9 | 18.3 | 450 |
| | 24-hour | 7 | 10.3 | 8.0 | 125 |
| | Annual | 2 | 3.0 | 2.3 | 25 |
| Total PM ₁₀ | 24-hour | 29 | 97.2 | 62.2 | 50 |
| | Annual | 13 | 34.1 | 22.2 | 20 |
| Total PM _{2.5} | 24-hour | 15 | 35.6 | 24.6 | 25 |
| | Annual | 4 | 10.3 | 6.7 | 8 |
| Benzene | 24-hour | 2 | 6.0 | 3.7 | 2.3 |
| | Annual | 1 | 2.2 | 1.5 | 0.45 |
| 1,3-butadiene | 24-hour | 0.4 | 0.8 | 0.6 | 10 |
| | Annual | 0.1 | 0.2 | 0.1 | 2 |

Note: Bolded values indicate an exceedance of the most stringent AAQO

6.2.1 Summary of Key Findings

The air quality evaluation shows that local and regional air quality are predicted to be lower with the Project as compared to without it. Of the three scenarios considered, the 2031 scenario with the Project has the lowest predicted maximum concentrations for all pollutants and averaging periods. The 2031 with Project will increase vehicle capacity, and have a higher average travel speed and increased dispersion of pollutants near the bridge.

When comparing the existing (2011) road configuration scenario to 2031 without the Project (i.e., with the Tunnel still operational), there is a predicted improvement in some of the concentrations due to reduction in vehicle emissions through more stringent regulations, better technology, and turnover of the vehicle fleet.

When compared to the 2031 scenario without the Project, the 2031 scenario with the Project is predicted to result in further improvements in local air quality. While the 2031 scenarios with and without the Project both benefit from the same fleet emission improvements, the 2031 scenario with the Project also benefits from less congestion and higher vehicle speeds associated with the proposed Highway 99 improvements and Tunnel replacement. Some of the improvements related to the reduction in congestion have not been accounted for in this modelling, meaning the 2031 with Project scenario is a conservative estimate of the impact on air quality.

In the 2011 and 2031 scenarios without the Project, maximum predicted pollutant concentrations generally occur nearest the entrances to the Tunnel. Because the Tunnel is an enclosed structure, vehicle emissions can only exit through the Tunnel openings and exhaust fan towers. All of the emissions occurring inside the Tunnel are therefore concentrated and released over a small area. The new bridge, being elevated, will enable increased airflow along the entire crossing, resulting in improved dispersion of emissions and consequent improvement in local air quality near the bridge. The model shows that the locations of the maximum 1-hour concentration in the 2031 with Project occurs in the area south of the Bridge, near Highway 17A. The 24-hour and annual maximum concentrations with the Project are located in the area of Westminster Highway, which is a result of increased vehicle capacity resulting in more vehicles using Highway 99.

Overall ambient concentrations of certain pollutants exceed the most stringent AAQO under all three scenarios considered in this study; however, the number of pollutants that show an exceedance, as well as the degree of exceedance are similar in both of the 2031 scenarios, while the 2031 with Project scenario has significantly higher vehicle capacity and reduced congestion for the region.

Dispersion Modelling Plan

Dispersion Modelling Plan

An electronic version of this plan is available from:

www.bcairquality.ca/reports/model-plans-instructions.html

GENERAL

Date: **February 15, 2016**

Facility Name, Company, Location (Lat, Long): **George Massey Tunnel Replacement Project**

Air Quality Consultant and Contact Name: **WSP**

Ministry Contact Name:

Li Huang

Air Quality Meteorologist

Clean Air Environmental Standards Branch

Ministry of Environment

3rd Floor, 2975 Jutland Road

Victoria, BC V8T 5J9

Tel: (250) 953-3433 Fax: (250) 356-5496

Level of Assessment (1, 2 or 3) and also provide rationale for the proposed level of assessment:

Level 3 - This project is going through the BC environmental assessment process and covers a large spatial area.

Does this plan follow a modelling approach similar to that taken in a previous air quality assessment already reviewed and accepted by the Ministry? If so, provide the project name and Ministry contact:

Yes, this project follows methodologies developed for other large transportation infrastructure projects including the Sea to Sky Highway, Low Level Road Replacement, Port Mann Highway 1 and South Fraser Perimeter Road.

PROJECT DESCRIPTION AND GEOGRAPHIC SETTING

Provide an overview of the project description, including process description and the purpose of the dispersion modelling study.

To assess the impacts from vehicle traffic on air quality as it relates to the replacement of the George Massey Tunnel. This assessment will model three scenarios

- 1. Current configuration of Highway 99 between Bridgeport and Highway 91**
- 2. Current configuration with 2031 traffic of Highway 99 between Bridgeport and Highway 91**

3. Highway 99 between Bridgeport and Highway 91 with a 10-lane bridge replacing the tunnel with 2031 traffic

Future vehicle traffic volumes were obtained via traffic modelling while the fleet profiles were developed based on data from Metro Vancouver.

Provide a description of the following:

- ◆ Terrain characteristics within domain: flat terrain or complex terrain (i.e., will complex flow need to be considered?)
- ◆ Dominant land cover: urban, rural, industrial, agricultural, forested, rock, water, grassland

Within the 1-kilometer Local Assessment Area (LAA), which extends 1-kilometer from the modeled road link, the dominant land cover is agricultural and urban. Much of the urban land cover occurs in the northern portion of the LAA. The area is characterized as flat terrain at or near sea-level. Complex air flow will not be considered.

DISPERSION MODEL

Selected Dispersion Model:

- ◆ List model(s) and version to be used (see Section 2).

CALMET v6.334

CALINE3

- ◆ Specify any non-guideline models or versions (i.e., beta-test versions) planned for use (Section 2.3.1). Provide rationale.

CALINE3 was included in the previous version of the dispersion modelling guideline. It is currently EPA approved for transportation related dispersion modelling. The CAL3QHC model is built on the CALINE3 algorithms and was not used in this modelling assessment as it is for specialized modelling.

- ◆ If modifications to any of the models are planned, provide a description and the rationale (Section 2.3.2).

The CALINE3 model has been modified to allow for more receptors. No other changes to the source code have been made.

Default Switch Settings

- ◆ For AERMOD identify any switch settings that will be different than the recommended defaults (Section 7.7). Provide rationale.

N/A

- ◆ For CALMET/CALPUFF identify any key switch settings in CALMET and CALPUFF that will be different from the “black (do not touch)” defaults as per Tables 6.2 and 7.1. Provide rationale.

No CALMET switches have been changed.

- ◆ If the CALMET model is used, provide:
 - a CALMET domain map that also shows the locations of surface meteorological stations and upper air stations **Provided below.**
 - anticipated grid resolution: 500 (m)
 - number of grids in X and Y direction (NX = 340 , NY = 220)
 - vertical levels (m): 0 , 20 , 40 , 80 , 160 , 320 , 600 , 1500 , 3000

CALMET is used only to generate a single point of meteorology near the project site. Metro Vancouver operates ambient air quality monitoring stations which also record surface meteorology. Six Metro Vancouver stations were used along with a WRF prognostic data set. In addition to the six Metro Vancouver stations, the Environment Canada surface meteorology station located at the Vancouver International Airport was used in order to provide all of the parameters required by CALMET. The stations used were:

- **T13 – North Delta**
- **T15 – Surrey East**
- **T17 – Richmond South**
- **T18 – Burnaby South**
- **T38 – Annacis Island**
- **T39 – Tsawwassen**
- **Vancouver Airport – Environment Canada station**

AERMOD and Receptors

If the AERMET/AERMOD model is used, provide the following:

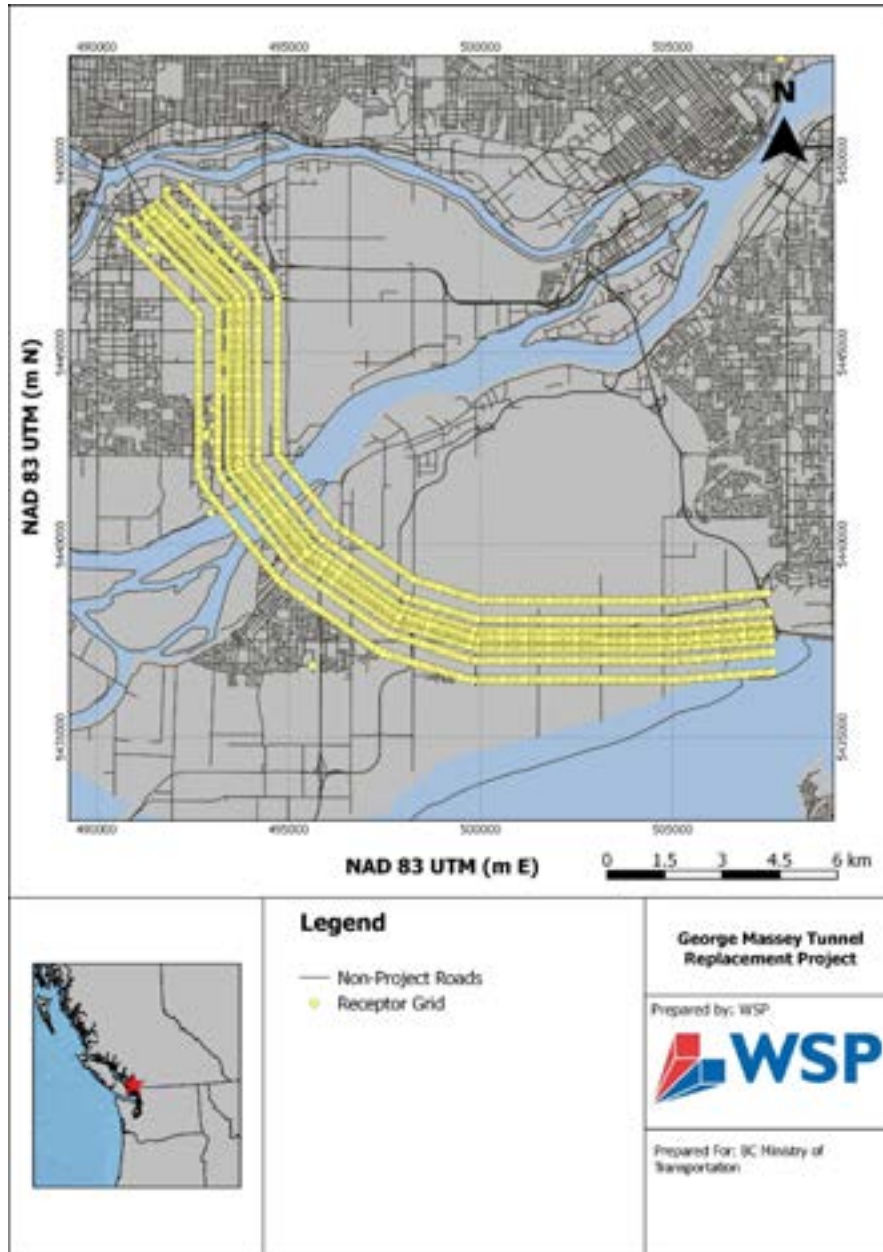

- ◆ proposed receptor grid spacing (see Section 7.2):
- ◆ an AERMET/AERMOD domain map that shows the locations of surface meteorological stations, upper air stations and receptor grid
- ◆ anticipated sensitive receptors (see Section 7.4) and also indicate them on the domain map (if applicable)
- ◆ receptor (flagpole) height (m) (see Section 7.5):

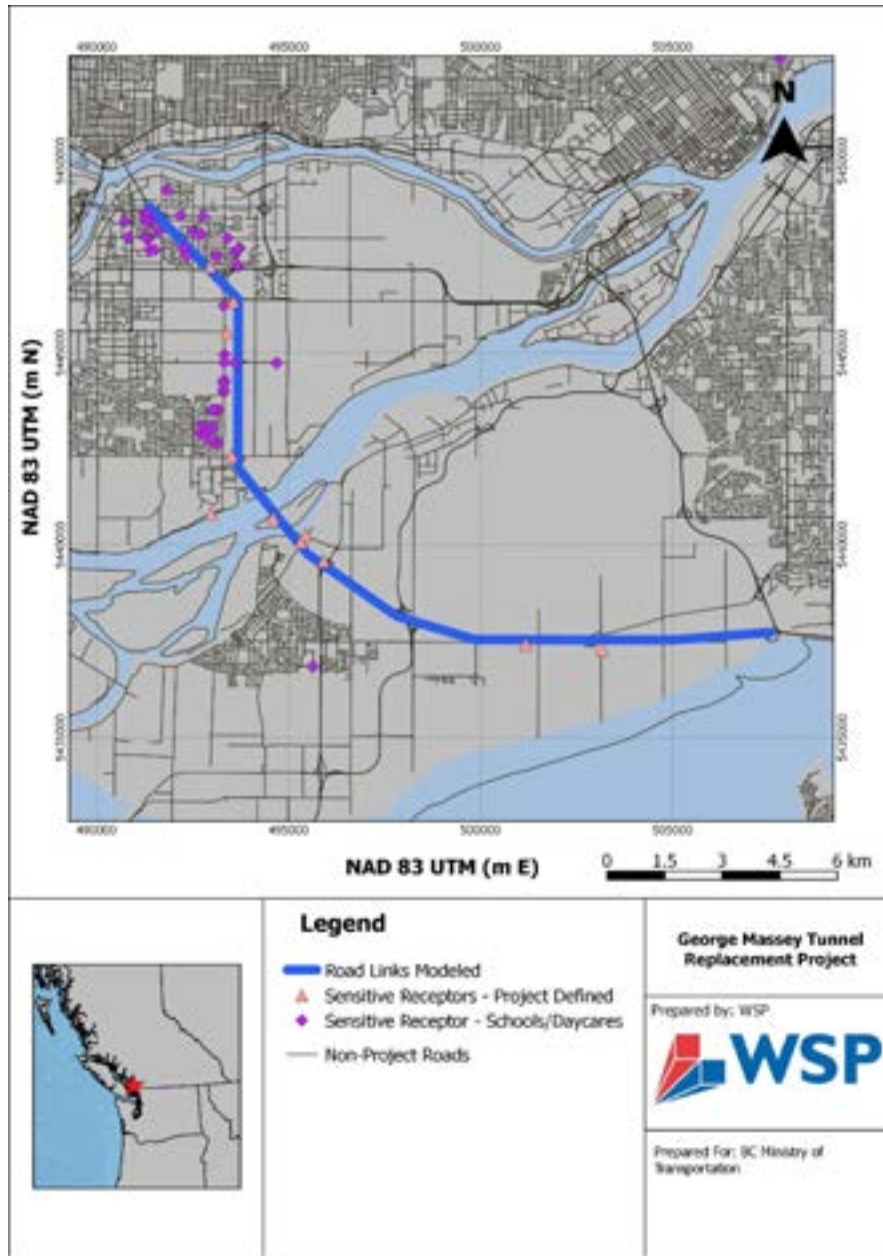

CALPUFF and Receptors

If the CALPUFF model is used, provide the following:

- ◆ proposed receptor grid spacing (see Section 7.2):
- ◆ a map of the CALPUFF domain and receptor grid
- ◆ anticipated sensitive receptors (see Section 7.4)) and also indicate them on the CALPUFF domain map (if applicable)
- ◆ receptor (flagpole) height (m) (see Section 7.5):

CALPUFF is not used but the receptor grid used in CALINE is shown below. Receptors are placed at intervals of 5, 10, 15, 20, 25, 50, 100, 250, 500 and 1000 meters perpendicular to the road. These lines of receptors are spaced in 100 meter intervals along the roadway. Sensitive receptors are shown in the second figure below. The sensitive receptors are all of the schools, daycares, care homes and hospitals occurring within the LAA as well as sensitive receptors identified by the project team. All receptors are placed at 0m.

PLANNED MODEL OUTPUT: AIR QUALITY ASSESSMENT NEEDS

Output Requirements for

What model output is required for decision makers and stakeholders? (i.e. what is the purpose of the assessment?). Circle as appropriate.

- ♦ Air Quality concentrations, depositions, visibility, fogging, icing, other (specify)

Tables and Figures for Level 1 Assessment:

- ◆ **maximum concentration of contaminants predicted including location and corresponding meteorological conditions**
- ◆ printout of AERSCREEN model output

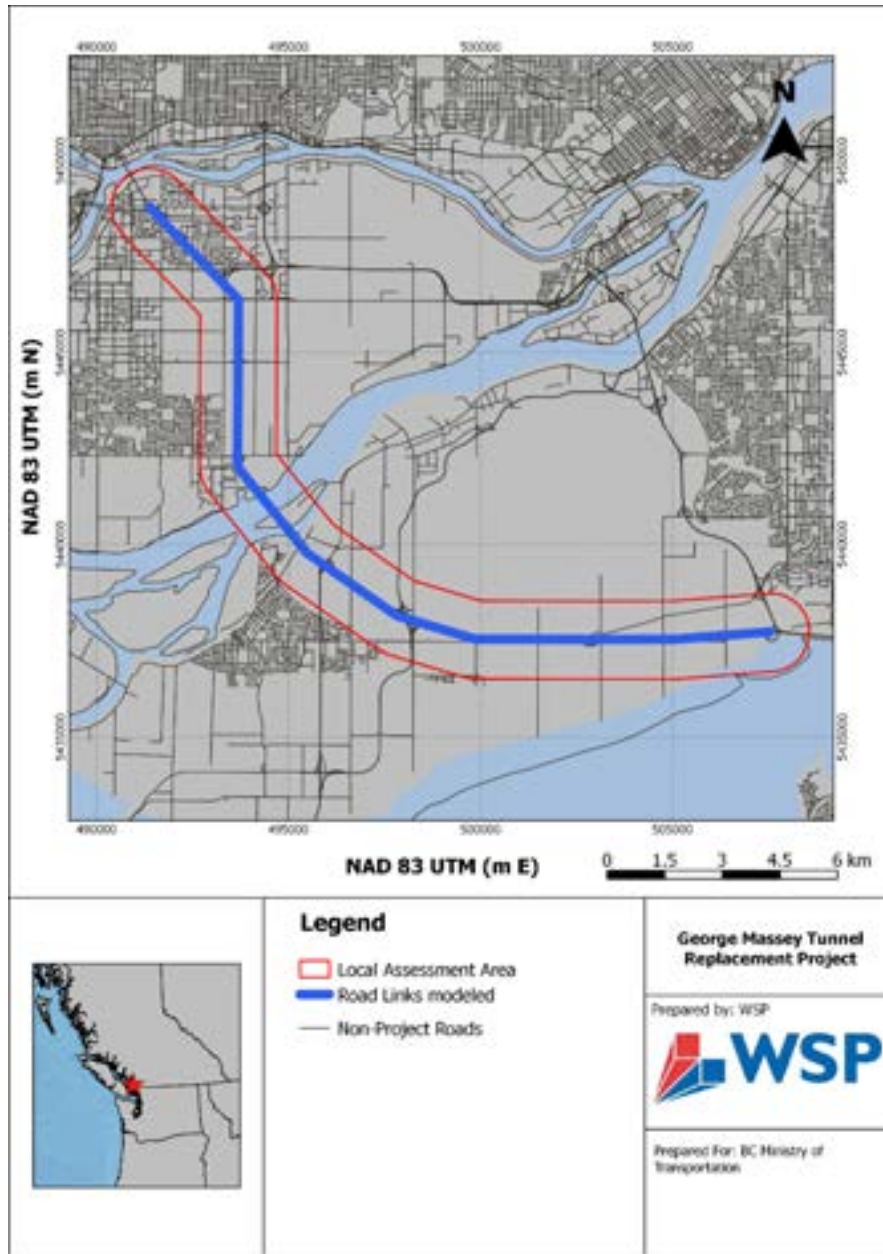

Tables and Figures for Level 2 and 3 Assessments (see detailed list in Section 8.3.2):

- ◆ **spatial distribution maps of air quality parameters (maximums, exceedance frequencies, annual averages)**
- ◆ **tables of maximum short and long time average air quality parameters (locations and associated meteorological conditions)**
- ◆ **tables of air quality parameters at select receptors of interest (maximums, frequency distributions)**
- ◆ tables of air quality parameters under certain emission situations (upsets, start-up)
- ◆ output spatial scale: **near-field (<10 km)**, local (<50 km), regional (>50 km)
- ◆ special output required for vegetation, health risk or visibility assessments
- ◆ other (specify):

EMISSION SOURCES AND CHARACTERISTICS

Provide a map showing the source locations, buildings, and facility fence line.

The LAA and road links are shown in the figure below.

Model Emission Scenarios

If applicable, describe the different model emission scenarios required for the assessment if multiple options are under consideration. For example, different source characteristics (stack dimensions, emission rates) or source arrangements (locations, types, buildings) may need separate modelling runs to examine the air quality implications of different scenarios.

To assess the impacts from vehicle traffic on air quality as it relates to the replacement of the George Massey Tunnel. This assessment will model three scenarios

1. **Current configuration of Highway 99 between Bridgeport and Highway 91**

2. Current configuration with 2031 traffic of Highway 99 between Bridgeport and Highway 91
3. Highway 99 between Bridgeport and Highway 91 with a 10-lane bridge replacing the tunnel with 2031 traffic

Future vehicle traffic volumes were obtained via traffic modelling while the fleet profiles were developed based on data from Metro Vancouver. Congestion is considered in the 2011 and 2031 without project scenarios along Link 2 (the tunnel) while traffic is free flowing in the 2031 with project scenario for all links.

CALINE has the ability to model a few types of roads including roads that are at grade and bridge links. Based on an investigation of the source code, these two road types result in identical executions of the code. Additionally, CALINE restricts the road height to 10 meters above ground level. In reality, the bridge will be at a height higher than 10 meters. It is expected that as the height of the bridge increases, dispersion improves and concentrations would be lower at ground level receptors. Therefore 10 meters is a conservative estimate of the predicted concentrations near the bridge.

Contaminants Emitted for Each Emission Scenario

Provide the following details of the sources to be modelled:

Specify Source, Type, Contaminants (extend Table as necessary)

| Emission Number | Description | Type: Point (P), Area (A), Line (L), Volume (V) | Contaminants (SO ₂ , NO _x , PM _{2.5} . .) | Basis of Emissions (Section 5.3) |
|-----------------|---|--|--|---|
| Link 1 | Bridgeport to Westminster Highway | L | VOC, CO, NO ₂ , SO ₂ , NH ₃ , PM ₁₀ , PM _{2.5} , Benzene, Naphthalene, 1,3-butadiene, Formaldehyde, Acetaldehyde, Acrolein, Benzo(a)pyrene | <input type="checkbox"/> current emission limits <input type="checkbox"/> proposed emission limits <input checked="" type="checkbox"/> other (specify & justify) Emissions are based on fleet profiles from the EMME/2 traffic model and Metro Vancouver fleet profiles. Emission factors are from the MOVES2012b vehicle emission simulator. |
| Link 2 | Westminster Highway to George Massey Tunnel/Replacement | L | VOC, CO, NO ₂ , SO ₂ , NH ₃ , PM ₁₀ , PM _{2.5} , Benzene, Naphthalene, 1,3-butadiene, | <input type="checkbox"/> current emission limits <input type="checkbox"/> proposed emission limits <input checked="" type="checkbox"/> other (specify & justify) |

| | | | | |
|--------|---|---|--|---|
| | | | Formaldehyde, Acetaldehyde, Acrolein, Benzo(a)pyrene | Emissions are based on fleet profiles from the EMME/2 traffic model and Metro Vancouver fleet profiles. Emission factors are from the MOVES2012b vehicle emission simulator. |
| Link 3 | George Massey Tunnel/Replacement to Highway 17A | L | VOC, CO, NO ₂ , SO ₂ , NH ₃ , PM ₁₀ , PM _{2.5} , Benzene, Naphthalene, 1,3-butadiene, Formaldehyde, Acetaldehyde, Acrolein, Benzo(a)pyrene | <p>___current emission limits ___proposed emission limits</p> <p><u> X </u>other (specify & justify)</p> <p>Emissions are based on fleet profiles from the EMME/2 traffic model and Metro Vancouver fleet profiles. Emission factors are from the MOVES2012b vehicle emission simulator.</p> |
| Link 4 | Highway 17A to Highway 17 | L | VOC, CO, NO ₂ , SO ₂ , NH ₃ , PM ₁₀ , PM _{2.5} , Benzene, Naphthalene, 1,3-butadiene, Formaldehyde, Acetaldehyde, Acrolein, Benzo(a)pyrene | <p>___current emission limits ___proposed emission limits</p> <p><u> X </u>other (specify & justify)</p> <p>Emissions are based on fleet profiles from the EMME/2 traffic model and Metro Vancouver fleet profiles. Emission factors are from the MOVES2012b vehicle emission simulator.</p> |
| Link 5 | Highway 17 to Ladner Trunk Road | L | VOC, CO, NO ₂ , SO ₂ , NH ₃ , PM ₁₀ , PM _{2.5} , Benzene, Naphthalene, 1,3-butadiene, Formaldehyde, Acetaldehyde, Acrolein, Benzo(a)pyrene | <p>___current emission limits ___proposed emission limits</p> <p><u> X </u>other (specify & justify)</p> <p>Emissions are based on fleet profiles from the EMME/2 traffic model and Metro Vancouver fleet</p> |

| | | | | |
|--------|---------------------------------|---|---|---|
| | | | | profiles. Emission factors are from the MOVES2012b vehicle emission simulator. |
| Link 6 | Ladner Trunk Road to Highway 91 | L | VOC, CO, NO ₂ , SO ₂ , NH ₃ , PM ₁₀ , PM _{2.5} , Benzene, Naphthalene, 1,3-butadiene, Formaldehyde, Acetaldehyde, Acrolein, Benzo(a)pyrene | <input type="checkbox"/> current emission limits <input type="checkbox"/> proposed emission limits <input checked="" type="checkbox"/> other (specify & justify) Emissions are based on fleet profiles from the EMME/2 traffic model and Metro Vancouver fleet profiles. Emission factors are from the MOVES2012b vehicle emission simulator. |

* for PM emissions indicate whether it is filterable, or filterable + condensable, or if unknown (see Section 3.6)

Source Emission Rate Variability

Do emissions have sub-hourly variation (e.g., blow-down flares with high emission peaks during the hour)? If so, describe the approach to assess air quality implications of those sub-hourly high emission peaks.

Not considered.

Describe the approach to assess air quality implications under the 25, 50, 75% emission scenario. See Section 3.4.2.

N/A

If there are batch processes, provide a temporal emission profile (emission rate vs time) for each batch process.

N/A

Describe anticipated abnormal emission scenarios (e.g., start-up and shut-down) and their anticipated frequency of occurrence. See Section 3.4.3.

N/A

BASELINE CONCENTRATION

- ◆ Indicate method used to determine baseline concentrations for each pollutant (Section 8.1):

monitoring data (Section 8.1.1 and 8.1.2)

_____ establish monitoring program (Section 8.1.3)

_____ modelled sources (Section 8.1.5)

_____ other method (describe)

- ◆ If existing monitoring data to be used, complete the following Table:

Representative Air Quality Measurements

| Station Name (Lat./Long./ or indicate on map) | Period of Record (start/end date) | Contaminants Measured |
|---|-----------------------------------|---|
| T13 – North Delta | 2008 - 2012 | NO ₂ , O ₃ , PM _{2.5} |
| T15 – Surrey East | 2008 - 2012 | NO ₂ , CO, O ₃ , PM _{2.5} |
| T17 – Richmond South | 2008 - 2012 | NO ₂ , CO, O ₃ , SO ₂ , PM _{2.5} |
| T18 – Burnaby South | 2008 - 2012 | NO ₂ , CO, O ₃ , SO ₂ , PM _{2.5} , PM ₁₀ |
| T31 – Richmond Airport | 2008 - 2012 | NO ₂ , CO, O ₃ , SO ₂ , PM _{2.5} , PM ₁₀ |
| T39 - Tsawwassen | 2008 - 2012 | NO ₂ , CO, O ₃ , SO ₂ , PM _{2.5} |

- ◆ If baseline concentrations are anticipated to change in the future due to planned significant reductions or increases in emissions, provide a description of how these will be accounted for (e.g., construction of a nearby new facility or the planned decommissioning of a currently operating facility) and the uncertainties involved in estimating future emissions.

BUILDING DOWNWASH

- ◆ Potential for building downwash. Please provide rationale if building downwash is not modelled.

N/A

- ◆ If building downwash included, provide a site map to indicate buildings to be processed by BPIP-PRIME, and also complete the following Table:

| Source Height (m) | Distance from the Source to the Nearest Building (m) | Building Length (m) | Building Height (m) | Building Width (m) |
|-------------------|--|---------------------|---------------------|--------------------|
| | | | | |
| | | | | |
| | | | | |

GEOPHYSICAL DATA INPUT

Topography and Land Use Data

- ◆ Terrain data (specify source of data) and an elevation map for the model domain:

GeoGratis – Canadian Digital Elevation Data (CDED) at 1:50,000

- ◆ Land use data (specify source of data) and a land use map for the model domain:

Baseline Thematic Mapping digital land use data at 1:250,000 scale from the BC Land and Resource Data Warehouse

Surface Characteristics

For AERSCREEN, provide seasonal values of surface characteristics (surface roughness, albedo and Bowen ratio) for input to MAKEMET.

N/A

For Level 2 and 3 Assessments, Indicate if recommended seasonally varied surface characteristics (surface roughness, albedo, Bowen ratio, etc.) (see Section 4.3 and 4.4) are used for the dispersion modelling study. If not, provide the proposed surface characteristics and the rationales.

No as there is not a substantial change in the land use between seasons along the project.

METEOROLOGICAL DATA INPUT (FOR LEVEL 2 AND 3 ASSESSMENTS ONLY)

Surface Meteorological Data

If surface observation data are used, provide a map with the location of each surface meteorological station identified and also provide the following:

Surface data was not used. A single point of meteorology was required for use in CALINE and CALMET was run in NOOBS mode in order to provide a grid point near the project.

| Surface Met Data and Location (lat/long or indicate on map) | Data Source MOE, MV, MSC, Site Specific, other (specify) ¹ | Period of Record (start/end data) ² | % of Wind Speeds = 0.0 ³ | Anemometer Height (m) | Parameters |
|---|---|--|-------------------------------------|-----------------------|--|
| T13 (see map below) | MV | Jan 1, 2012 – Dec 31, 2012 | 0.93% | 14.3 | Wind Speed, Wind Direction, Temperature, Relative Humidity |
| T15 (see map below) | MV | Jan 1, 2012 – Dec 31, 2012 | 0.51% | 16.9 | Wind Speed, Wind Direction, Temperature |
| T17 (see map below) | MV | Jan 1, 2012 – Dec 31, 2012 | 2.6% | 12.5 | Wind Speed, Wind Direction, Temperature |
| T18 (see map below) | MV | Jan 1, 2012 – Dec 31, 2012 | 0.07% | 19.9 | Wind Speed, Wind Direction, Temperature, Relative Humidity |
| T38 (see map below) | MV | Jan 1, 2012 – Dec 31, 2012 | 0.85% | 10.0 | Wind Speed, Wind Direction, Temperature, Relative Humidity |
| T39 (see map below) | MV | Jan 1, 2012 – Dec 31, 2012 | 9.01% | 10.8 | Wind Speed, Wind Direction, Temperature, |

| | | | | | |
|---------------------|-----|----------------------------|------|------|---|
| | | | | | Relative Humidity |
| YVR (see map below) | MSC | Jan 1, 2012 – Dec 31, 2012 | 0.2% | 10.0 | Wind Speed, Wind Direction, Temperature, Relative Humidity, Pressure, Ceiling Height, Cloud Cover |

1. If data from a non - Ministry, MV or MSC station are planned to be used, follow guidance in Section 5.2.3
2. For data completeness and data filling, follow guidance in Section 5.5
3. For light and no wind conditions, follow guidance in Section 5.6

Upper-Air Meteorological Data

If upper air meteorological data are used provide the following:

| Station Name | Period of Record (start/end date) ¹ | Distance between the Upper Air Station and Project (km) |
|--------------|--|---|
| | | |
| | | |

¹. For data completeness and data filling, follow guidance in Section 5.5.

NWP Model Output

If NWP output (different than the province-wide WRF output) used provide the following:

- ◆ Mesoscale Meteorological Model (Name\Version\Model Configuration): **WRF-NMM**
- ◆ Model Output Provider: **SENES Consultants Ltd**
- ◆ Domain (attach a map showing the horizontal extent):

- ◆ Horizontal and Vertical Grid Resolution and Height of Each Vertical Level: **~3km horizontal resolution with 18 sigma levels**
- ◆ Data Period (start/end date): **January 1, 2011 – December 31, 2011**
- ◆ Four Dimensional Data Assimilation is applied (Yes or No): **Yes**

NWP model output use (circle one below for the selected dispersion model):

- ◆ AERMET/AERMOD:
 - Extract pseudo surface station and pseudo upper air sounding (as input to AERMET), or
 - Create .SFC and .PFL files (AERMOD-ready files, skip AERMET)

- ◆ CALMET:
 - NWP only, or
 - Surface station and NWP, or
 - Surface station, upper air sounding, and NWP, or
 - Other (specify):

TREATMENTS

NO to NO₂ Conversion:

Identify the method to be used (Section 8.2).

X Ambient Ratio Method

- ◆ indicate monitoring station(s)

Data from T18 – Burnaby South were used to develop the curve. Other data from T13 – North Delta and T17 – Richmond South were used to validate the curve

____ OLM:

- ◆ specify O₃ concentration and how it was selected,
- ◆ if non default in-stack ratios are used, specify and provide rationale.

____ PVMRM (for AERSCREEN and AERMOD only):

- ◆ specify O₃ concentration and how it was selected,
- ◆ if non default equilibrium ratios and/or in- stack ratios are used, specify and provide rationale.

Chemical Transformation:

- ◆ Specify transformation method and provide details on inputs if Secondary PM_{2.5}, Acid Deposition or Visibility effects are to be estimated. Depending on the transformation method, this could include ammonia, ozone, hydrogen peroxide concentrations, nighttime loss and formation rates for nitrates and sulphates.

N/A

Particle Deposition:

- ◆ If non-recommended particle size distributions (see Section 3.6) are used, provide Table of particle emission (including heavy metals if modelled) size/density distribution and indicate the basis for the Table.

N/A

Stagnation:

- ◆ Provide an estimate of the frequency of stagnation based local meteorological data if available. If AERMOD is proposed, provide methodology on how stagnation periods will be treated (see Section 10.2).

N/A

Shore/Coastal Effects:

- ◆ If included, indicate whether sub-grid-scale Thermal Internal Boundary Layer option is selected along with the required input coastline coordinate data (see Section 10.3).

N/A

Plume Condensation (Fogging) and Icing:

- ◆ Indicate if this will be included (Section 10.6).

N/A

QUALITY MANAGEMENT PROGRAM

Model Input Data

Indicate the tests that will be undertaken to assure the quality of the inputs.

For the geophysical input data:

- ◆ **contour plot of topography**
- ◆ **plots of land use and land cover**

For the meteorological data:

- ◆ **wind rose (annual and/or seasonal)**
- ◆ **frequency distribution of surface wind speeds**
- ◆ **average hourly temperature plot (annual and/or seasonal)**

If NWP output is used, describe the tests undertaken to assure the quality of the output (Section 6.1)

- ◆ **wind rose at selected locations and heights (annual and/or seasonal)**
- ◆ **average hourly temperature plot at selected locations and heights (annual and/or seasonal)**
- ◆ **wind field plots for selected periods that indicate topographic influences such as channeling and thermally generated flows**

Model Output Data

For CALMET/CALPUFF applications, provide a list of the tests conducted to confirm the quality of the model output (intermediate pre-processing files and concentration/deposition predictions).

With respect to the pre-processed files that are prepared for CALPUFF input, there are several tests listed in Section 9.1.1 and 9.1.2 to check the output from the pre-processing utility programs to confirm that they have been properly processed. These are related to checking:

- ◆ terrain, land use
- ◆ sources (locations and elevation) and emission characteristics
- ◆ meteorological data (locations) and tests to confirm proper processing of the raw meteorological data (units, parameters)
- ◆ receptor locations and elevations

For CALMET output there are several tests listed in Section 9.1.3 to test the quality of the generated meteorological fields. These are related to reviewing the following:

- ◆ wind field maps (surface and different elevations) for select periods where topographic influences (channeling, thermally driven flows) would be evident
- ◆ wind roses and selected locations and elevations (annual, seasonal)
- ◆ frequency distributions of various meteorological parameters (annual, seasonal) such as PG-stability class, mixing heights
- ◆ plots of hourly average parameters such as temperature, mixing height, precipitation at key locations (seasonal and annual)

Note: The Ministry may require all computer files associated with the modelling to be submitted upon request.

MINISTRY REVIEW OF PLAN AND REVISIONS

A modelling plan can change over the course of developing the air quality assessment so acceptance of the initial submission of the plan is on the basis of the best information provided to date. Changes to the plan (additions, modifications) should be noted and agreed to with the Ministry as necessary. An updated Dispersion Modelling Plan may be necessary.

Glossary

| Term | Definition |
|---|--|
| ambient noise level | The total noise level in the acoustic environment, including the source(s) of interest. |
| atmospheric noise | airborne anthropogenic noise. |
| A-weighted decibel (dBA) | An A-weighted decibel is a unit of sound that has been compensated for the sensitivity of the ear to different frequencies by a dBA filter. |
| day-night equivalent sound level (L_{dn}) | A 24-hour noise exposure expressed in dBA. In computing L_{dn} , all noise levels occurring between 10 p.m. and 7 a.m. are increased by 10 dBA to reflect the greater sensitivity of residential communities to noise at night. |
| daytime equivalent sound level (L_d) | Equivalent Sound Level (L_{eq}) for the time period from 7 a.m. to 10 p.m. |
| decibel (dB) | Standard unit of measurement for sound pressure level. |
| equivalent sound level (L_{eq}) | That steady sound level which, over a given time period, would result in the same overall sound energy exposure as would the actual fluctuating level. Expressed in units of dBA. |
| nighttime equivalent sound level (L_n) | Equivalent Sound level (L_{eq}) for the time period from 10 p.m. to 7 a.m. |
| noise | In general, noise is considered to be unwanted sound. |
| noise-sensitive receptor | Humans who might experience sound and vibration energies. A noise-sensitive receptor is a person who is most influenced by such noise or vibration by virtue of where they live relative to the sources. Specific behaviour and physiology (e.g., age, general health) may make a person more vulnerable to noise and vibration. |
| Project Area | The Project footprint plus the Project disturbance area. |
| Project disturbance area | All lands and lands under water, except the Project footprint, which are subject to disturbance during Project construction and required for maintenance activities during Project operation. |
| Project footprint | The land and water surface occupied by the Project facilities and structures. |

| Term | Definition |
|-------------------------|---|
| sound | Minute fluctuations in atmospheric (air) pressure usually created by vibrating objects or moving fluids such as loudspeakers, drums, or moving vehicles. Humans interpret these pressure fluctuations occurring over the audible frequency range (approximately 20 Hz to 20,000 Hz) as sound. |
| sound level | The intensity of sound expressed on a logarithmic scale. The basic unit of sound level is the decibel (dB). |
| sound level meter | An instrument that measures and logs sound pressure levels. A Type 1 sound level meter is the industry standard for precision field measurements used in environmental noise assessments, and is accurate to +/- 1 dBA. |
| sound-level contour map | Spatial representation of ranges of noise levels, analogous to the ground-elevation contours found on topographical maps. |
| sound pressure level | Sound pressure level = $20 \log_{10} (p/p^0)$ dB: The sound pressure level of a sound in decibels is equal to 20 times the logarithm to base 10 of the ratio of the RMS sound pressure to the reference sound pressure 20 mPa (2×10^{-5} Pa). |
| usage factor | A term used in the prediction of Project construction noise that refers to the percentage of time during a construction shift when a particular piece of construction equipment typically operates and produces noise. |

1.0 Scope of Study

This document provides technical details on the atmospheric noise study undertaken to support the environmental assessment of the George Massey Tunnel Replacement Project (Project). An overview of the key study components and their major objectives is provided in **Table 1**. A review of available information pertaining to atmospheric noise conditions along the Project alignment was undertaken to inform the study and identify the need for additional data.

Table 1 Atmospheric Noise Study Components and Major Objectives

| Component | Major Objective(s) | Brief Overview |
|--|---|--|
| Existing noise monitoring | Establish existing (i.e., pre-Project) ambient noise environments | Continuous monitoring (24-hour, 48-hour, and shorter periods) of noise levels at locations representative of noise-sensitive land uses within the Project alignment. |
| Post-construction (i.e., operation phase) traffic noise forecast | Predict operation and total noise exposures for 2030 ¹ | Noise modelling using the projected future traffic data to predict Project-related changes in traffic noise exposures over a 10-year design horizon at noise-sensitive receptors along the Project alignment. |
| Construction phase noise forecasts | Estimate the range of potential effects of Project-related construction noise at adjacent noise-sensitive receptors | Estimation of Project-related construction noise using a generic construction noise prediction methodology used in the environmental impact assessment of several previous major B.C. highway projects and evaluating noise levels received by sensitive receptors from construction activities. |

¹ the year for which future traffic volume projections were available

1.1 Regulatory/Policy Context and Assessment Guidelines

1.1.1 The Ministry's Noise Policy

The atmospheric noise study for the Project was guided primarily by the Ministry's *Policy for Assessing and Mitigating Noise Impacts from New and Upgraded Numbered Highways* (Wakefield Acoustics Ltd. 2014), hereafter referred to as the Ministry's 2014 noise policy. The Ministry's 2014 noise policy is a tool that promotes the protection of public health by identifying highway traffic-related noise impacts from construction of new highways and upgrading of existing highways, and the potential need for mitigation measures.

The Ministry's 2014 noise policy provided the methods for the following aspects of the study:

- Choice of appropriate and representative baseline noise monitoring sites
- Baseline noise monitoring with the day-night equivalent sound level (L_{dn}) noise metric
- Prediction of future noise levels due to the Project at baseline monitoring locations
- Total future noise level determination in situations where the baseline conditions are not dominated by the Project
- Moderate and severe Project-related noise impact identification
- Noise mitigation requirements

In accordance with the Ministry's 2014 noise policy, 2030 was adopted in this study as the assessment year for projected future conditions with the Project. The Ministry's 2014 noise policy does not address potential noise impacts related to highway construction. Guidance on the control of construction noise and minimization of construction noise impacts are provided in the relevant section of the Ministry's *Standard Specifications for Highway Construction* (B.C. MOTI 2012). Best practices for the control of highway construction noise will be applied.

1.1.2 European Environment Agency Guidance

The European Environment Agency's (EEA) *Good Practice Guide on Noise Exposure and Potential Health Effects* identifies noise indicators that are relevant to human health, as defined by the World Health Organization (WHO 1946 as cited in EEA 2010). These indicators are the day-night equivalent sound level (L_{dn}), the daytime equivalent sound level (L_d), and the nighttime equivalent sound level (L_n). WHO (1946) provides the appropriate baseline noise metrics for the atmospheric noise study.

1.1.3 United States Environmental Protection Agency Guidance

Noise levels required to protect public health and welfare against hearing loss, annoyance, and activity interference were identified by the United States Environmental Protection Agency (U.S. EPA) in 1974. These noise levels are contained in the document titled *Information on Levels of Environmental Noise Requisite to Protect Public Health and Welfare with an Adequate Margin of Safety* (U.S. EPA 1974). As with the EEA 2010 guide, this document identifies the L_{dn} , L_d and L_n as the appropriate baseline noise metrics for environmental noise impact assessments; these metrics were therefore used in this atmospheric noise study.

1.1.4 Canada Mortgage and Housing Corporation Guidance

Guidance from the Canada Mortgage and Housing Corporation (CMHC) includes a manual on procedure for modelling traffic noise exposures at wayside locations under relatively simple highway configurations (CMHC 1981). The CMHC noise model (specifically, the baseline adjustment method (BAM)) was used in the atmospheric noise study to estimate future noise levels for the Project, where conditions permit its use.

1.1.5 Highway 17/South Fraser Perimeter Road Project Data

The *South Fraser Perimeter Road Noise Impact Assessment Technical Volume 13* (Wakefield Acoustics Ltd. 2006) of the EA Application prepared for the Ministry for the South Fraser Perimeter Road (SFPR) project has been adopted as a reference for the Project. In the SFPR noise impact assessment, two approaches to construction noise impact assessment were presented: the EPA method and the International Standards Organization (ISO 1996) method. The generic construction noise estimation technique used on the SFPR and other recent major B.C. highway projects has been used in the Project atmospheric noise study to estimate construction noise exposures from the Project.

1.1.6 Highway 99/Ladner Trunk Road Interchange Upgrade Project Data

The Ministry commissioned the Highway 99/Ladner Trunk Road interchange upgrades in 2012. Noise exposures were assessed at fronting residential units in the northeast quadrant at Delta View. Residential noise impacts were not identified at Delta View under the 1993 noise policy, nor was mitigation required under that policy. The noise assessment is provided in *Report 13-M259-1 Burns Drive/Highway 99 Community Noise Assessment* (Wakefield Acoustics Ltd. 2013).

The principal noise metric obtained for the Project, through monitoring, is the day-night average sound level (L_{dn}), which is the primary noise metric used in the Ministry's 2014 noise policy. Noise monitoring also provided the daytime average sound level (L_d), which is the equivalent sound level (L_{eq}) between 7 a.m. and 10 p.m., and the nighttime average sound level (L_n), which is the L_{eq} between 10 p.m. and 7 a.m. While these latter two noise metrics are not used directly in the Ministry's 2014 noise policy, they provide important information relevant to the human health effects assessment

2.0 Study Methods

2.1 Study Area Considerations

Noise monitoring was conducted along the Highway 99 corridor from the Bridgeport Road interchange in City of Richmond (Richmond) to the Highway 91 interchange in Corporation of Delta (Delta). The boundaries of the study area were determined based on two considerations:

1. The lateral distance beyond which noise impacts, as defined in the Ministry's 2014 noise policy, are not likely to occur.
2. The lateral distance beyond which daily-average noise levels from traffic related to the Project would not be expected to exceed what is considered by CMHC and U.S. EPA to be acceptable for residential land uses.

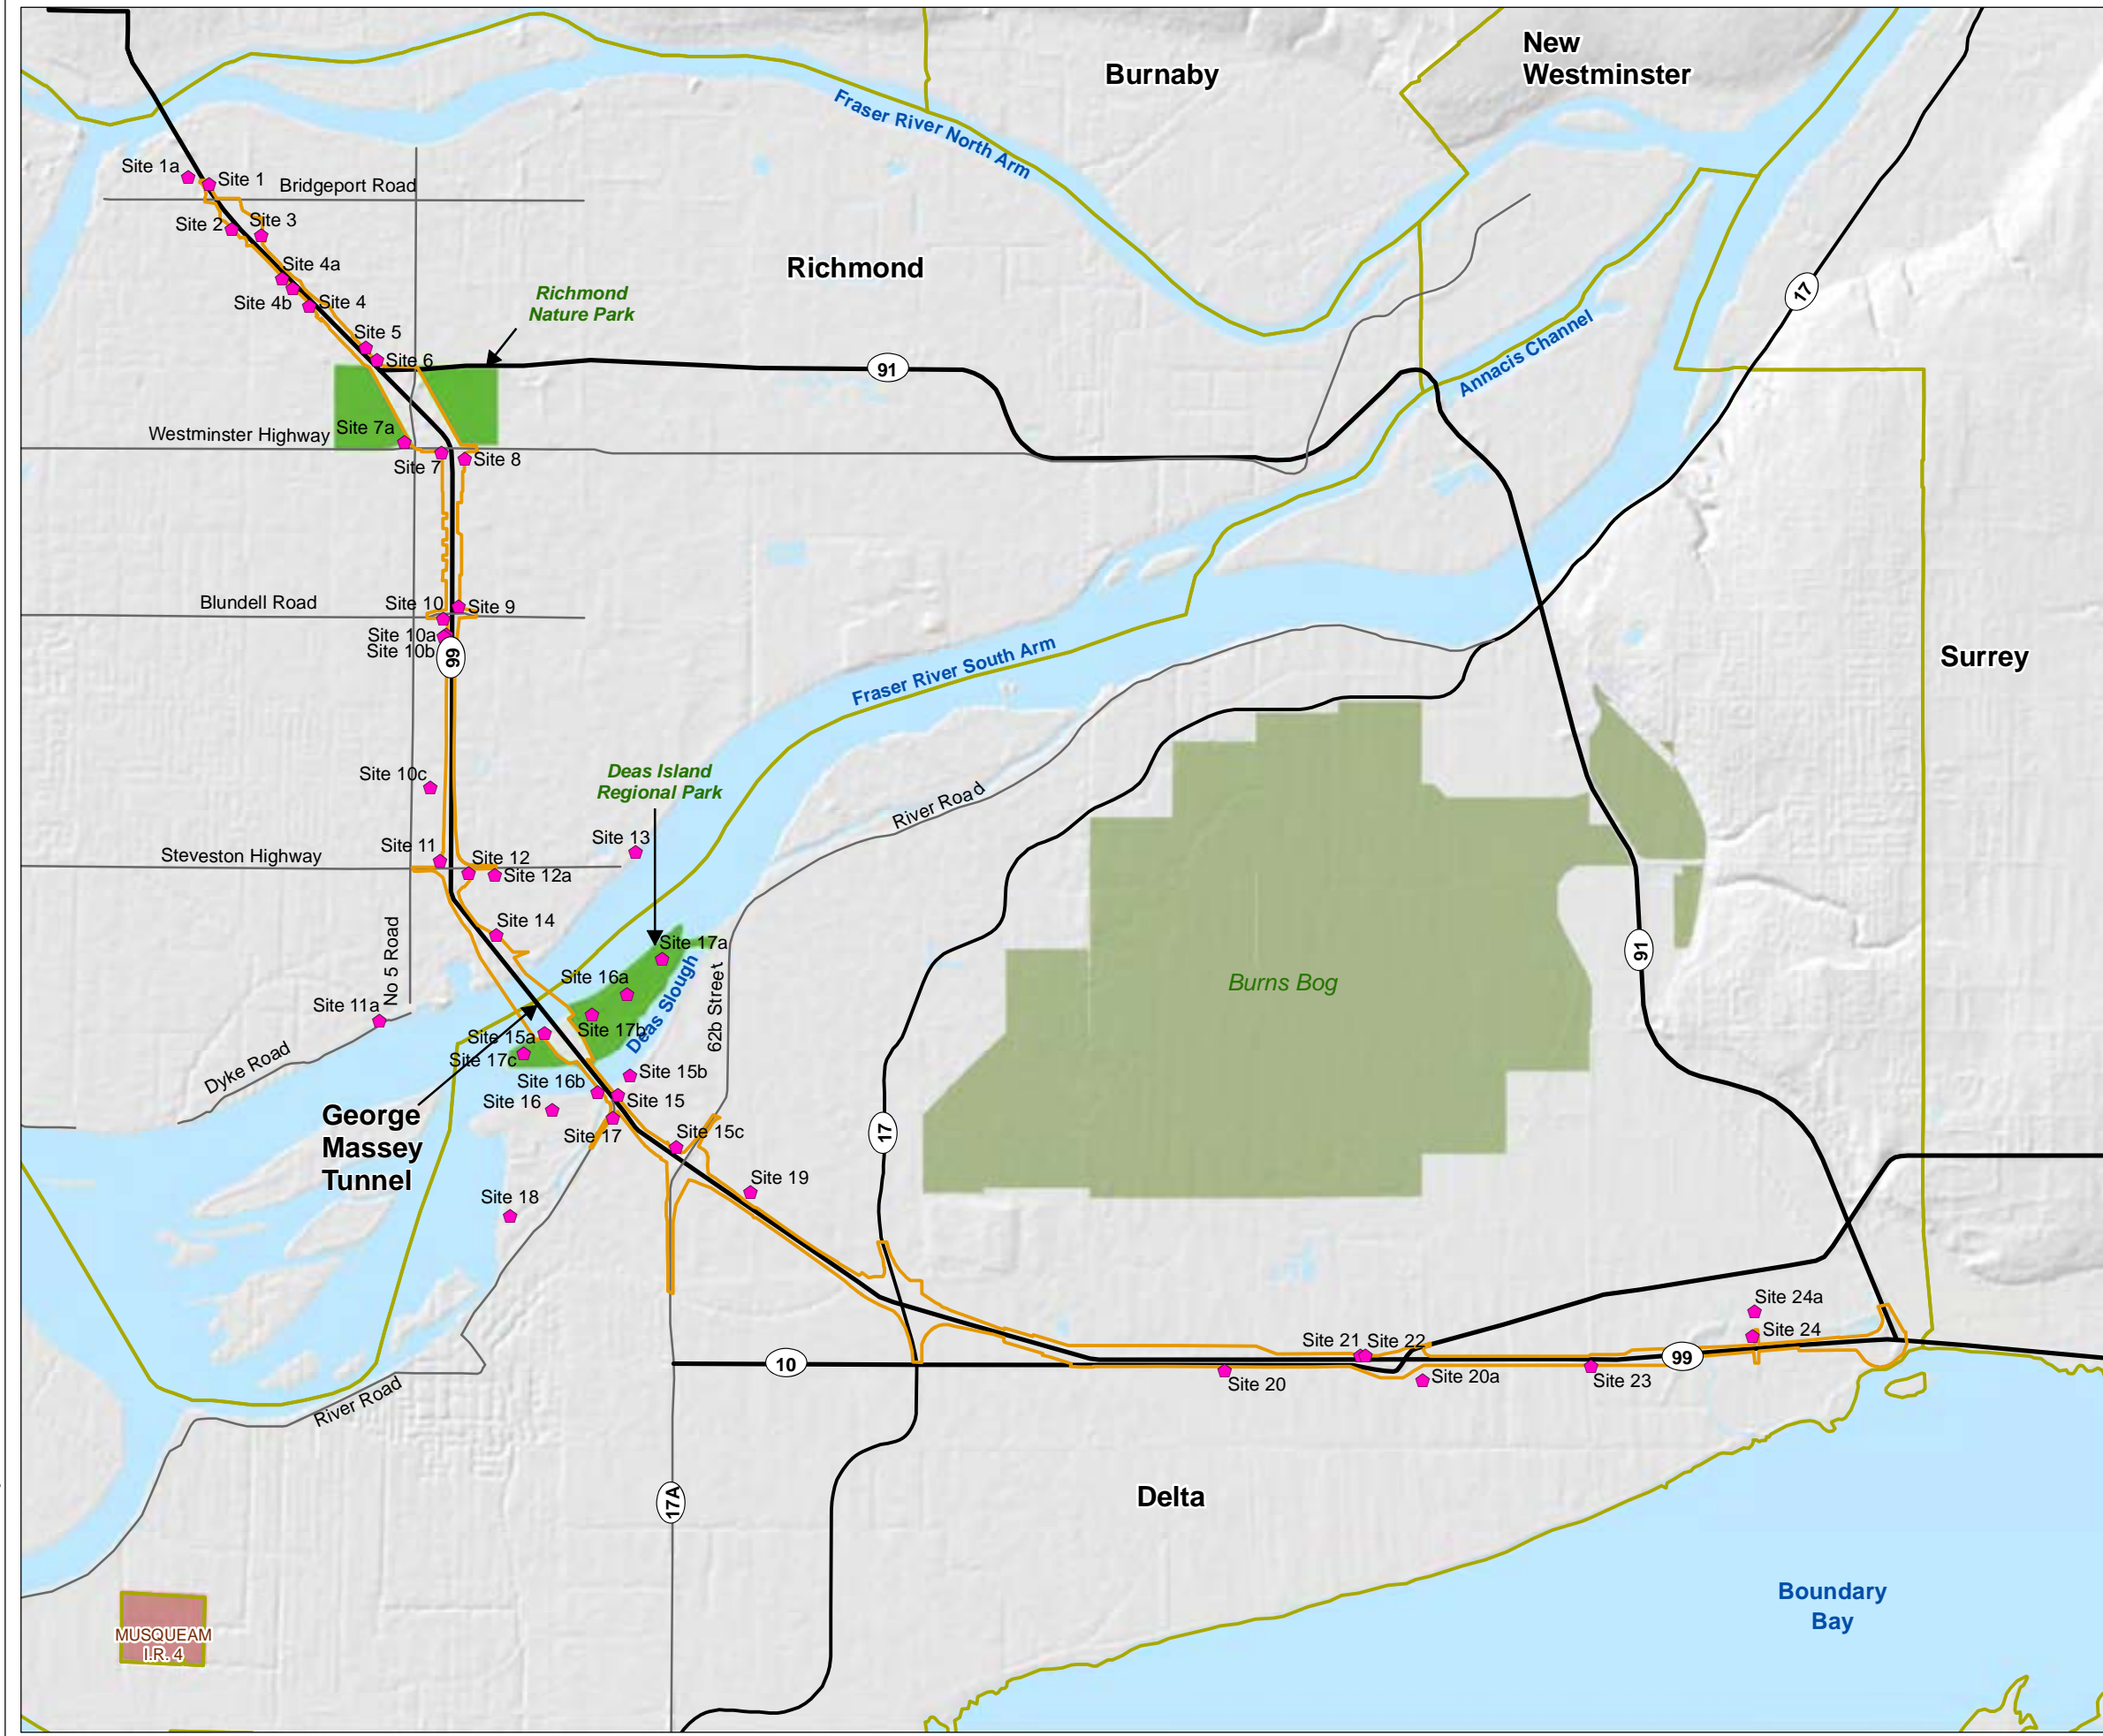

The distance at which these two conditions would be met depends on traffic volume, average speed, and heavy truck component of the future traffic stream on Highway 99. The distance also depends on the elevation of the traffic above the ground and the nature of the ground surface between the highway and the noise-sensitive receptors. Where sound travels close to the ground, and in particular where the intervening surface is acoustically absorptive or soft (e.g., grass, farmland, wooded areas), the reduction of sound levels over moderate distances is relatively high. Where the sound source is elevated well above the ground, and in particular where the intervening surface is acoustically reflective or hard (e.g., pavement, water), the rate of attenuation of sound levels with distance is generally much lower.

For these reasons, for the majority of the study area within which Highway 99 is close to natural ground level and largely bordered by agricultural or undeveloped lands, the study area width extends 500 m from either side of the Project footprint. This width is sufficient to capture the following:

- Residences north of the Fraser River on both sides of No. 5 Road, which parallels Highway 99 to the west, and Sidaway Road, which parallels Highway 99 to the east.
- Residences south of the Fraser River along 64th, 72nd, 80th, 88th, 96th Streets, Burns Drive, and Ladner Trunk Road.

In the vicinity of the new bridge, where Highway 99 traffic will be elevated well above natural ground level, and where much of the surrounding surfaces are water, the study area extends approximately 1,600 m from either side of the Project footprint, since the rate of decrease in sound levels over these acoustically reflective surfaces is lower. This distance is sufficient to capture the following:

- Condominium buildings located along Riverport Way in Richmond on the north bank of the Fraser River to the east of Highway 99 and the new bridge.
- Townhouses along Regatta Way, Delta, to the west of Highway 99.
- Residences and parks along Dyke Road and residences along Rice Mill Road in Richmond.
- Residences along River Road and Admiral Way in Delta.

2.2 Temporal Scope

The atmospheric noise study was designed to document the existing baseline noise environment at representative residential and non-residential noise-sensitive locations within the study area in 2013 and 2014². The baseline noise levels include pre-Project Highway 99 noise as well as noise from all other sources.

The temporal boundary for the atmospheric noise study is based on the maturation of the traffic regime, which, in accordance with the Ministry's 2014 noise policy, is taken to be 10 years after Project completion. The anticipated Project completion date of 2022 puts the 10-year post-completion horizon year at 2032; however, 2030, the year for which future traffic volume projections were available, was used as the horizon year for this assessment. The difference in forecasted noise levels due to traffic growth from one year to the next is negligible. The relevant noise metrics for the atmospheric noise study include L_{dn} , L_d , and L_n . These three metrics were measured at all long-term monitoring noise sites and were estimated at short-term monitoring sites. Future noise levels with the Project were predicted using either a baseline adjustment method or highway noise modelling software. The following methods and procedures were used to achieve this:

1. Baseline (pre-Project) noise monitoring (yielding the L_{dn} , L_d and L_n) was conducted at 41 sites along Highway 99 between Bridgeport Road in Richmond and Highway 91 in Delta.
2. The CMHC baseline adjustment method was used to predict post-Project noise exposures in terms of L_{dn} , L_d and L_n for 2030 at noise-sensitive locations within the portions of the Project where the planned changes to the horizontal and vertical alignments of Highway 99 will be minor.

² Baseline noise monitoring was mainly conducted in autumn 2013. Additional noise monitoring was conducted in spring 2014. Relevant baseline monitoring had also been conducted in 2012 on earlier Highway 99 improvement projects (see **Section 2.3**).

3. DataKustik's CadnaA noise prediction software version 4.3.143 was used to model post-Project noise exposures in terms of L_{dn} , L_d and L_n for 2030 at noise-sensitive locations in the vicinity of the new bridge and its approaches, where the planned changes in the vertical alignment of Highway 99 will be major.
4. Construction noise exposures at noise-sensitive locations were estimated in terms of L_{dn} , L_d and L_n using a generic method³ previously used in other major highway projects in B.C.

2.2.1 Baseline Noise Measurements 2012 - 2014

The continuous baseline noise monitoring was conducted using four Larson-Davis model 820 and model 812 environmental noise monitors, a Larson-Davis SoundTrack LxT®, and two Larson-Davis SoundExpert™ LxT sound level meters (see **Appendix A** for instrumentation details), with one instrument set up per site. These digital instruments meet or exceed American National Standards Institute (ANSI) S1.4: Specifications for Sound Level Meters (1983), including Type 1 sound level meters, and are capable of sampling the ambient sound level many times per second and storing the resulting sound level data for subsequent analysis and display. The instruments were set to collect a complete statistical description of the noise environment every 15 minutes. At each site, these instruments store, among many other noise descriptors, the day-night equivalent sound level (L_{dn}). The L_{dn} is a single-number descriptor of the average sound energy level over a 24-hour period with a 10 decibel (dB) adjustment applied to the noise levels measured during nighttime hours. L_{dn} is expressed in units of A-weighted decibels (dBA) and is the noise metric employed in the Ministry's 2014 noise policy.

Microphones were mounted on poles approximately 1.7 m above ground level in positions where overall noise exposures were considered to be representative of the residential façades that will, in the future, be most directly exposed to noise from Highway 99 traffic.

The baseline noise monitoring was conducted between October 2 and November 22, 2013 and between April 7 and 9, 2014 at 41 noise-sensitive locations (sites) along the Highway 99 alignment between Bridgeport Road in Richmond and Highway 91 in Delta. Continuous unattended noise monitoring was conducted at 41 long-term sites (i.e., over 24-hour periods at 22 sites, and over a 48-hour period at one quality control site). Additional baseline noise data was obtained from an earlier study done in relation to the Highway 99/Burns Drive improvement

³ This procedure has been used in previous applications for the Sea-to-Sky Highway Improvement Project, SFPR project and Port Mann/Trans-Canada Highway project.

project. This study focused on project noise effects at the Delta View Life Enrichment Centre located near the Ladner Trunk Road Interchange. Since the study was conducted in 2013, the traffic noise levels obtained are considered sufficiently current to serve, as appropriate, as baseline data for the current Project. To supplement the long-term noise monitoring conducted at the 23 sites, short-term (typically 30 minutes) attended daytime monitoring sessions were conducted from October 2013 to April 2014 at an additional 18 sites.

In accordance with the Ministry's 2014 noise policy, baseline noise monitoring sites were selected to be representative of residential enclaves, schools, Places of Worship, and passive parks. The large majority of sites were residential and typically a baseline monitoring site was selected to be representative of a group of residences having similar highway noise exposures. In each case, the microphone was placed outdoors near a residence fronting onto the Project and in a location having the greatest exposure to noise due to the Project. The principal noise metric collected at these monitoring sites was the L_{dn} , the primary noise metric utilized in the Ministry's 2014 noise policy, and widely in use internationally. The 24-hour monitoring also yielded the L_d , and the L_n .

Short-term noise monitoring was conducted at 18 sites. Each short-term monitoring session was conducted concurrently with a long-term session at a control site located within the same contiguous segment of Highway 99. Short-term sites and their nearby control sites may have had different setbacks or elevations with respect to the highway, but their noise exposures were considered to be similarly dominated by Highway 99 traffic. Short-term monitoring was conducted only in locations where existing and expected future noise environments are dominated by Highway 99 traffic noise. The appropriate L_{dn} for each short-term site was then obtained by comparing the equivalent sound level (L_{eq}) measured over the specific 30-minute monitoring period at the short-term site with the L_{eq} measured during the identical 30-minute period at the control site. Specifically, the difference between the two 30-minute L_{eq} values was then applied to the L_{dn} measured at the control site to obtain the L_{dn} at the short-term site.

The noise level data obtained at the twenty-three 24-hour and 48-hour monitoring sites are presented in **Appendix B**, along with photos and descriptions of the sites and the dominant source(s) of baseline noise at in each site.

2.2.2 Prediction of Future Noise Conditions

Baseline Adjustment Method

The baseline adjustment method (BAM) is a means of predicting the effects of a highway improvement project on noise levels at a representative location. The BAM can be used most effectively in situations where the highway alignment (horizontal and vertical) is not changing to any substantial degree; for example, where additional through lanes are being added to one or both sides of a fixed highway centreline; where the horizontal or vertical alignment is being modified only slightly; or where the traffic volume, posted speed, and/or level of service will change. The north and south segments of the study area, excluding the proposed bridge and its approaches, lend themselves to the BAM approach. For purposes of applying the BAM, the study area was divided into segments as presented in **Table 2**.

Table 2 Highway 99 Segments for Assessment of Operational Noise

| Highway 99 Mainline Segments | Site Numbers |
|---|--|
| A. Bridgeport Road to Westminster Highway | 2, 3, 4a, 4b, 4, 5, 6, and 7a |
| B. Westminster Highway to Steveston Highway | 7, 8, 9, 10, 10a, 10b, 10c, 11, and 13 |
| C. Steveston Highway to Highway 17A | 11a, 12, 12a, 14, 15, 15a, 15b, 15c, 16a, 16b, 17, 17a, 17b, 17c, and 18 |
| D. Highway 17A to Highway 17 | 19 |
| E. Highway 17 to Ladner Trunk Road | 20, 21, 22 |
| F. Ladner Trunk Road to Highway 91 | 20a, 23, 24, 24a |

In applying the BAM, reliance has been placed principally on the manual highway noise prediction procedure contained in the CMHC document Road and Rail Noise; Effects on Housing (CMHC 1981). This procedure allows 24-hour average highway noise exposures to be estimated based on the following traffic parameters:

- Average daily traffic volume
- Heavy truck mix
- Posted speed
- Highway grade
- Receptor setback distance from highway centreline
- Elevation of highway and receptors above surrounding ground surface
- Nature (i.e., acoustically hard or soft) of the intervening ground surface

Using these input parameters, the 24-hour Equivalent Sound Level, or $L_{eq}(24)$, at the receptor location may be estimated. Similarly, if one or more of these parameters is to be changed as a result of a proposed highway improvement project, then the effects of any such changes on the $L_{eq}(24)$ can be predicted. Assuming the distribution of traffic between the 15 daytime hours (07:00 to 22:00) and nine nighttime hours (22:00 to 07:00) does not change, the predicted change in L_{dn} (the noise metric used in the Ministry's 2014 noise policy) will be the same as that in $L_{eq}(24)$.

As an example, consider the hypothetical situation in which a new lane is to be added on each side of an existing two-lane highway around a fixed centreline, and, as a result, the total traffic volume will increase by 30%, the heavy truck mix will increase from 5% to 8% and the posted speed will increase from 80 to 100 kmph. The $L_{eq}(24)$ at residences set back more than about 30 m from the highway would then be expected to increase by approximately 4.0 dBA (1.0 dBA from volume growth, 1.0 dBA from heavy truck mix growth and 2.0 dBA from the speed increase). Therefore, if the baseline noise level at a particular location was, for example, L_{dn} 63 dBA, the post-Project level would be expected to be approximately L_{dn} 67.0 dBA.

The BAM was used to predict Project noise effects in all but segment C. Further details of the BAM are provided in **Appendix C**. The existing and future traffic data on which the BAM estimates are based are also presented in **Appendix C**.

Traffic Noise Modeling

Where the planned improvements to Highway 99 include major and complex changes to the horizontal and vertical alignment, such as will occur at the new bridge and its approaches, the BAM is not appropriate since it cannot account for the effects of such substantive changes in highway geometry. Therefore, a three-dimensional computer-based highway noise model was developed to predict the noise levels that will exist 10 years after Project completion (2030) throughout the portion of the study area that includes the new bridge and its approaches (segment C in **Table 2**). The computer-based noise model runs a proprietary version of the U.S. Federal Highways Administration (FHWA) Traffic Noise Model (TNM®) Version 2.5 (U.S. FHWA 2004). The input parameters required for the TNM 2030 noise model are as follows:

- Proposed horizontal and vertical alignment of the bridge including the north and south approaches
- Forecast annual average daily traffic volumes (AADT) in 2030, and day-night traffic split

- Proposed posted speed (km/hr)⁴
- Expected distribution of traffic in the proposed lanes across the 10-lane bridge, taking into account the percentage of heavy trucks and the day-night traffic split
- Proposed pavement type
- Noise receptor locations within the study area
- Nature of intervening ground (acoustically hard water and pavement versus acoustically soft grass)
- Presence of noise-shielding elements such as bridge deck parapet
- Presence of natural noise-shielding elements such as forest belts
- Relevant ground elevation contours within the study area
- Average weather conditions

Further details on noise modeling are provided in **Appendix C**.

2.2.3 Construction Noise

The levels of construction noise that may be generated by the Project were estimated using a generic construction noise prediction methodology that has been employed during the environmental impact assessment phases of several previous major B.C. highway projects, including the Sea to Sky Highway Improvement Project, PMH1 and the SFPR project. Construction noise analysis was carried out for all mainline segments as shown in **Table 3**. Further details are presented in **Appendix D**.

Table 3 Segments for Estimating Construction Noise

| Mainline Segments | Site Numbers |
|--|--|
| A - Bridgeport Road to Westminster Highway | 2, 3, 4a, 4b, 4, 5, 6, and 7a |
| B - Westminster Highway to Steveston Highway | 7, 8, 9, 10, 10a, 10b, 10c, 11, and 13 |
| C - Steveston Highway to Highway 17A | 11a, 12, 12a, 14, 15, 15a, 15b, 15c, 16a, 16b, 17, 17a, 17b, 17c, and 18 |
| D - Highway 17A to Highway 17 | 19 |
| E - Highway 17 to Ladner Trunk Road | 20, 21, 22 |
| F – Ladner Trunk Road to Highway 91 | 20a, 23, 24, 24a |

⁴ Light vehicles are assumed to travel at the posted speed. Heavy trucks assumed to travel at posted speed on level ground but at reduced speeds on grades.

2.2.4 Quality Control

Baseline noise data were collected in a consistent fashion at all sites with 24-hour noise-monitoring sessions being repeated at certain locations to verify the reproducibility of the noise levels. Instrumentation was consistently field-calibrated and time-synchronized.

The Larson Davis model 820 and model 812 environmental noise monitors, and the Brüel & Kjær Type 2250 sound level meter, were recently calibrated by a certified National Voluntary Laboratory Accreditation Program calibration laboratory. The Larson Davis SoundExpert™ LxT sound level meters were new from the factory. Instruments were field-calibrated before and after each monitoring period using the appropriate field calibrator (Larson Davis CA250 Acoustic Calibrator, and Brüel & Kjær 4231).

3.0 Application of the Ministry's Noise Policy 2014

The Ministry's 2014 noise policy provides a procedure to assess if the noise environments which will exist within adjacent communities of a highway project, ten years after completion, warrant mitigation consideration. Mitigation consideration will depend on both the absolute post-project noise levels and whether they will exceed certain fixed upper limits, and on the magnitudes of project-related changes in noise levels relative to pre-project (baseline) conditions. The key features of the 2014 noise policy are listed below:

- The principal noise metric for residential areas is the Day-Night Average Noise Level, or L_{dn} .
- Two fixed upper noise limits are defined – L_{dn} 65 dBA for Moderate Impacts and L_{dn} 75 dBA for Severe Impacts.
- If post-project noise levels exceed either the 65 or 75 dBA fixed limit, the current project does not need to have increased residential noise exposures for mitigation consideration to be warranted. It is enough that post-project levels exceed one of the fixed thresholds.
- To be considered effective, mitigation measures must be capable, individually or in combination, of reducing post-project noise exposures by 5 dBA or more.
- For noise-sensitive land uses (e.g., residential developments) to be eligible for mitigation consideration, they must have received planning approval from the relevant local authority prior to the first public announcement of the highway project or the designation (through gazetting) of the affected lands as potential future highway right-of-way (ROW).
- Mitigation measures may be considered for implementation either within or outside the highway ROW.
- Mitigation in the form of vertical noise barriers (walls) are limited in height to 5 m, while earth berms and berm-wall combinations may be of any practical height.
- Mitigation costs and benefits are site- and project-specific. However, benchmark mitigation cost guidelines have been established as \$25,000 (in 2014 dollars) per directly-benefiting household where project-related noise impacts are Moderate, and \$40,000 where they are Severe.
- Mitigation measures may be considered for residences, schools, hospitals, Places of Worship, libraries, museums and passive parks (not including golf courses, active parks and playing fields). Mitigation for residences and schools is always considered if noise exposures warrant. Mitigation for other land uses is considered on a case-by-case basis.

Figure 2 and **Figure 3** present the mitigation thresholds from the 2014 noise policy in graphical form. In **Figure 2**, pre-project noise levels (L_{dn}) are plotted on the horizontal axis while total, post-project (10 years after project completion) noise levels are plotted on the vertical axis. Mitigation consideration is warranted for noise impact situations (intercept of pre-project and post-project noise levels) which fall within either Moderate or Severe impact zones. Mitigation is only carried out by the Ministry where total post-project noise levels are clearly dominated by highway traffic.

In **Figure 3**, pre-Project noise levels are shown on the horizontal axis while the Project-related increases in total noise exposure required to warrant mitigation consideration are plotted on the vertical axis. The Moderate and Severe noise impact threshold values of both **Figure 2** and **Figure 3** are presented in **Table 4**.

Figure 2 Project-related Traffic Noise Impact Thresholds

| 80.0 | - | 65.0 | 75.0 | - | - | 0.0 |

To be considered effective under the 2014 noise policy, mitigation measures should reduce total post-Project noise exposures by at least 5dBA.

4.0 Results

4.1 Baseline Noise Monitoring Results

The baseline noise monitoring results are presented in **Table 5** through **Table 7** and include the following:

- Noise monitoring site number
- Noise monitoring dates including start and stop times
- Noise monitoring duration
- Location of noise-sensitive receptor (microphone location)
- The existing land use of the site
- L_{dn} , L_d , and L_n

Further details of the noise monitoring sites, including site photos and noise level time histories, are provided in **Appendix B**.

Table 5 Results of Baseline Noise Monitoring (Sites 2 to 11a)

| Site # | Date | Duration ¹ | Noise Sensitive Receptor Location | Land Use | Ldn (dBA) | Ld (dBA) | Ln (dBA) |
|----------------|---------------------|-----------------------|---|----------------|-----------|----------|----------|
| 2 ² | Nov. 4 to 5, 2013 | 24 hrs | 22 Capella Garden, 9731 Capella Drive, Richmond, B.C. | Residential | 72.2 | 69.9 | 64.5 |
| 3 | Nov. 4 to 5, 2013 | 24 hrs | 10168 Caithcart Road, Richmond, B.C. | Residential | 69.7 | 68.2 | 61.4 |

| 10c | Nov. 1, 2013 | Short | Ling Yen Mountain Temple, 10060 No. 5 Road, Richmond, B.C. | Worship | - | 61.7 | - |
| 11 | April 7 to 8, 2014 | 24 hrs | 10640 No. 5 Road, Richmond, B.C. | Residential | 65.7 | 62.6 | 58.3 |
| 11a | April 9, 2014 | Short | 11551 Dyke Road, Richmond, B.C. | Municipal-park | - | 46.4 | - |

Notes:

- ¹ Actual run times may vary. Short-term measurements were typically 30 minutes. At short-term sites representing residences, the L_{dn}, L_d, and L_n were estimated through comparison with the full 24-hour noise histories measured at the relevant control site.
- ² In many residential land use situations, the receptor location is representative of a group of residences which are similarly exposed to Highway 99 noise. Such receptors are located in the fronting row of residences as per the Ministry's 2014 noise policy and, as such, generally receive the highest noise exposures of the group. In other cases, particularly in rural areas, the receptor represents one or two isolated residences. Highway noise exposures in the second row of residences are typically 3 to 5 dBA lower than in the fronting row.
- ³ Measurement duration was 13.75 hours instead of 24 hours.

Table 6 Results of Baseline Noise Monitoring (Sites 12 to 19)

Notes

- ¹ Due to the location of this site on the western property line of the Richmond Country Farm, noise levels there were influenced by traffic on the northbound off-ramp from Highway 99 to Steveston Highway. At more representative locations further east within this commercial property, noise from Highway 99 would have become more dominant.
- ² L_d (7.8 hours) 65.6 dBA measured Wednesday, Apr. 9, 2014.
- ³ L_d based on noise monitoring conducted at Control site 16, and site 16b on Nov. 6, and Nov. 22, 2013.
- ⁴ The noise monitoring conducted at Site 18 (Ernie Burnett Park) was intended to represent the nearby residences on Regatta Way.
- ⁵ Daytime noise levels at site 19 were affected by a traffic slowdown on Highway 99. Based on the levels observed after the slowdown cleared, it has been estimated that the average daytime noise level would have been approximately 8 dBA higher for much of the day without the slowdown. The baseline L_d, and L_{dn} for site 19 have therefore been adjusted upwards to correct for this traffic slowdown effect, which did not extend south past the Delta Works Yard.

Table 7 Results of Baseline Noise Monitoring (Sites 20 to 24a)

| Site # | Date | Duration | Noise Sensitive Receptor Location | Land Use | L _{dn} (dBA) | L _d (dBA) | L _n (dBA) |

4.2 Noise Modelling Results

The noise modelling results are presented in **Table 8** and **Table 9**, which include the following:

- Noise monitoring site number
- The noise-sensitive receptor location
- The existing land use of the site
- Baseline (2013) noise levels including L_{dn} , L_d , and L_n
- Total⁵ (2030) noise levels estimated by BAM or modelled by TNM, including L_{dn} , L_d , and L_n

Note that, at the majority of baseline noise monitoring sites, total baseline noise exposures are completely dominated by Highway 99 traffic. Therefore, in assessing the effects of the Project at these sites, total noise exposures in 2030 may be assumed to be numerically equal to Highway 99 traffic noise levels in 2030. However, at a small number of monitoring sites baseline noise levels were not completely dominated by Highway 99 traffic (i.e., there were noise contributions from non-Highway 99 sources). In such cases, total future (2030) noise exposures will not be exactly the same as 2030 Highway 99 traffic noise levels. The contributions of non-Highway 99 noise sources at a given site that will persist at least until 2030 must then be assessed and combined with predicted 2030 Highway 99 noise levels to obtain the total 2030 noise levels at that site⁶.

⁵ Total (2030) noise levels will be equivalent to traffic noise levels from the Project at Highway 99 traffic noise dominated sites.

⁶ These corrections have not been applied at this point, and as a result, Project-related noise impacts have been slightly overestimated at these locations.

Table 8 Baseline (2013)¹ and Total Future (2030) Noise Levels Estimated at BAM Sites

| Site # | Noise-Sensitive Receptor Location | Land Use | Baseline Noise Levels (dBA) | | | Total (2030) Noise Levels (dBA) | | |

Notes

¹ The baseline year is 2013 unless otherwise noted.

² This is the 2030 noise level that would be expected at site 7a if its total noise exposure was controlled by Highway 99 traffic. Since it is not, it is expected that the 2030 level will be much closer to the baseline level of 58 dBA, unless very substantial traffic growth occurs on Westminster Highway and No. 5 Road.

³ Daytime noise levels at site 19 were affected by a traffic slowdown on Highway 99. Based on the levels observed after the slowdown cleared, it has been estimated that daytime noise levels would have been approximately 8 dBA higher for much of the day without the slowdown. The baseline L_d, and L_{dn} for Site 19 have therefore been adjusted upwards to correct for this traffic slowdown effect.

⁴ Noise levels at site 20 were influenced by traffic on Ladner Trunk Road so that the baseline noise levels shown here are only partly due to Highway 99 traffic. Traffic on Ladner Trunk Road is expected to have subsequently been reduced with the opening of the SFPR. To correct for this effect, the baseline adjustment of 2.3 dBA has been only applied to the estimated Highway 99 component of the overall traffic noise.

⁵ Overall noise exposures at these sites were controlled by railway activities, so that Project noise effects will be negligible.

Table 9 Baseline (2013)¹ and Total Future (2030) Noise Levels at TNM/CadnaA Modelling Sites

| Site # | Noise-Sensitive Receptor Location | Land Use | Baseline Noise Levels (dBA) | | | Total (2030) Noise Levels (dBA) | | |

Notes

- ¹ The baseline year is 2013 unless otherwise noted.
- ² Due to its location on the west property line of this commercial property, baseline noise exposures at site 12 were influenced by traffic on the northbound off-ramp from Highway 99 to Steveston Highway. As such, the baseline level was higher than that predicted from the new bridge. At locations further east within this property, baseline levels would have been influenced more by Highway 99 through traffic, and somewhat larger Project effects would have been expected.
- ³ Noise levels at site 12a were influenced by Steveston Highway traffic. For this reason, predicted Project noise levels are slightly lower than the measured baseline levels.

5.0 Discussion

The key results of the atmospheric noise study, as well as discussions of reproducibility and data gaps, are presented in this section.

5.1 Key Findings

Existing levels of noise at noise-sensitive receptor locations within the study area as measured during the study period (2013) vary widely depending primarily on the setback distance of the monitoring sites from Highway 99 but also on the traffic conditions that prevailed within the immediately adjacent highway segment. The noise level histories obtained at these sites (presented in **Appendix B**) were generally consistent with noise environments dominated by highway traffic. At a few sites, noise contributions were made by non-Highway 99 sources. However, since these sources are typically arterial or local road traffic, they tended to display temporal patterns similar to those of highway traffic.

The key measurement results are summarized as follows:

- Existing noise levels measured at residential sites were as follows:
 - L_{dn} ranging from 51.5 to 75 dBA, with an average of 66.3 dBA
 - L_n ranging from 41.3 to 67.8 dBA, with an average of 59.2 dBA
- Existing noise levels measured within passive parks were as follows:
 - L_d ranging from 45.9 to 58, with an average of 49 dBA
- Existing noise measured at the schools and worship facilities were as follows:
 - L_d ranging from 61.7 to 71.8, with an average of 68.2 dBA
- Future 2030 noise levels at residences were predicted to be:
 - L_{dn} ranging from 52.5 to 77.3 dBA, with an average 68.3 dBA
 - L_n ranging from 42.9 to 70.1 dBA, with an average of 60.2 dBA
- Future 2030 noise levels within passive parks were predicted to be:
 - L_d ranging from 49.5 to 61.7, with an average of 55 dBA
- Future 2030 noise level at the school, daycares and, worship facilities were predicted to be:
 - L_d ranging from 65.3 to 75.2, with an average of 71.7 dBA
- Maximal construction noise levels at residences were estimated to be:
 - L_{dn} ranging from 39 to 84 dBA, with an average of 75 dBA (non-pile driving)
 - L_d ranging from 52 to 86 dBA, with an average of 70 dBA (pile driving)

The BAM assessments conducted within the mainline segments of Highway 99 contained within segments A, B, D, E and F (**Table 2**) revealed relatively small Project-related increases in L_{dn} to 2030. This is because the alignment of Highway 99 will generally not be significantly altered within these segments. Therefore, while the baseline noise levels at residences closest to the Project are typically quite high due to the high traffic volumes and relatively high vehicle speeds, the effects of the Project (largely due to volume growth and some anticipated speed increases) within these segments are not numerically large.

The TNM approach generated two key findings for the segment of Highway 99 that would include the new bridge and approaches (segment C in **Table 2**), 10 travel lanes, and a grade on the bridge approaches. For the segment of Highway 99 currently within the Tunnel, to be replaced with the new bridge and its approaches, it is predicted that there will be increased traffic noise levels in the areas (e.g., Deas Island Regional Park) that currently are shielded from much of the Highway 99 traffic noise by the Tunnel. To the south of the Tunnel portal, where Highway 99 is now at or near ground level (Deas Slough Bridge and southern approach), post-Project noise exposures created by traffic on the new bridge are predicted to be similar to, or even slightly lower than, baseline levels. This is because residences adjacent to this segment of Highway 99 currently receive only minimal noise shielding from a concrete roadside barrier, and are hence directly exposed to highway noise. With the Project, these residences will receive substantial noise shielding from the bridge deck parapet, which will largely block line-of-sight to the sources of traffic noise on the bridge and southern approach.

5.2 Reproducibility

The reproducibility (day-to-day variation) in measured baseline noise levels at locations adjacent to Highway 99 was assessed by conducting two consecutive 24-hour noise monitoring sessions at certain sites. At site 9 (residence/daycare at 12431 Blundell Road) the results of consecutive monitoring between October 29 - 30, 2013 and October 30 - 31, 2013 were L_{dn} 72.5 and L_{dn} 70.4 dBA, indicating a variability of approximately 2 dBA. Since this monitoring was conducted over Halloween, much of the variation in L_{dn} is attributable to atypical noise events associated with fireworks during the night⁷ of October 30.

⁷ The nighttime equivalent sound levels for October 30 and October 31, 2013 were L_n 65.9 dBA and L_n 62.8 dBA, respectively, i.e. it was 3.1 dBA noisier on the night of October 30. Fireworks were observed to be in use on both nights.

5.3 Data Gaps and Limitations

The following data gaps and limitations have been identified:

- **Variations in instrument sensitivity and highway traffic noise levels:** the level of accuracy and precision of the baseline measurements performed is ± 0.5 dBA for the instrumentation, and generally between ± 0.5 and ± 2 dBA for day-to-day variation, including meteorological conditions, traffic volume, speed variations and local activities. The day-to-day variation is closer to ± 0.5 dBA in the many situations where Highway 99 traffic is clearly the dominant noise source and setbacks are small. Baseline levels presented in **Table 5**, **Table 6**, and **Table 7** are subject to such variation. However, in the application of the Ministry's 2014 noise policy, it is accepted that there are inherent accuracy limitations to both the measurement and prediction of highway noise levels and the approach taken is to accept the noise levels produced using best practices in measurement and modelling and not to apply error bands or soft boundaries around the policy's mitigation thresholds.
- **Variations in non-highway noise sources:** at a small number of monitoring sites, baseline noise levels are not clearly controlled by Highway 99 traffic. Therefore, to predict the total future (2030) L_{dn} with the Project, it is necessary to establish the individual noise contributions from both the highway and any prominent non-highway sources. If the noise from the non-highway source(s) is not expected to vary over time (e.g., from an industry), its level may be added to the future Highway 99 noise level to obtain the total 2030 L_{dn} at a given site. If the non-highway noise is expected to vary over time, then ideally its anticipated future level should be established and combined with the future Highway 99 noise level to obtain the total 2030 L_{dn} . In most cases, the primary source of non-highway noise was traffic on other highways (Westminster and Steveston) and arterial roads. However, it was not possible to obtain projections of traffic growth on these other routes to 2030 with the Project, and the effects of any such increases in non-Highway 99 noise have therefore not been qualitatively accounted for herein. However, it is not expected that this limitation has influenced the magnitudes of forecast Project-related L_{dn} to any significant degree.
- Other non-Highway 99 noise sources that made non-trivial contributions to overall daily noise exposures at a few sites included industrial and shipping noise along the Fraser River, local traffic and activities, aircraft flyovers, and heavy rail movements. On October 31, 2013 (Halloween) in particular, atypical noise interference occurred at suburban noise monitoring sites. In some cases it was possible to extract the more prominent atypical noise events to adjust the measured L_{dn} . In other cases, this was not possible; therefore, some uncertainty was introduced as to how much of the baseline L_{dn} was due to Highway 99 and how much was due to other sources.

- **Uncertainty associated with baseline estimates at short-term site:** short-term monitoring sites situated on the opposite side of Highway 99 from their control sites, particularly in the vicinity of the Tunnel, potentially increase the uncertainty of the short-term sites' baseline L_{dn} estimates. Since traffic noise levels increase with average vehicle speed, and since traffic flow speeds tend not to be symmetrical (due to the counter-flow lane) in the congested areas around the Tunnel approaches, L_{dn} at short-term sites on the more free-flowing side of the highway could be slightly underestimated when based on an L_d obtained at control sites on the more congested side. An example of where this is expected to have occurred is in the vicinity of the Deas Slough and south Tunnel portal, where a slowdown occurs in the northbound lanes during the morning peak traffic period.
- **Limitations associated with speed profile data:** speed profiles provide hourly average traffic speeds at a given point along the highway and, as such, are useful for the analysis and interpretation of noise monitoring results, particularly where speed regimes are expected to change as a result of a project. However, only two speed profile stations, at Westminster Highway and Steveston Highway, were available from the Ministry. No speed profile was available near Blundell Road, for example. To resolve this data gap in the BAM, it was necessary to interpolate between the Westminster Highway and Steveston Highway speed profiles to make adjustments for traffic congestion near Blundell Road. This increased the uncertainty of the BAM estimates of the 2030 L_{dn} s at the Blundell Road sites.
- **Uncertainty associated with model calibrations:** The TNM model was calibrated by inputting the existing (2013) traffic volume and speed profiles into the model and adjusting the rate at which sound levels are attenuated with distance from the highway so as to achieve agreement with measured baseline noise levels. This is standard procedure when developing a TNM for a future highway situation. However, in the case of the new bridge, the noise sources (10 lanes of traffic ascending and descending the structure) are elevated well above the ground, and their noise is shielded to varying degrees (for ground level receptors) by the eastern and western bridge parapets. Because of the need to incorporate these unique features into the TNM for the new bridge, there is some uncertainty associated with use of a model calibration procedure based on sound propagation between sources and receptors located close to the ground.

Instrumentation

Noise monitoring was conducted using the instrumentation presented in **Table A1**. Continuous 24-hour noise monitoring was conducted in the fall of 2013 using up to four Larson-Davis (LD) environmental noise monitors (ENM) and in the spring of 2014 using two Larson Davis ENMs, and LD sound level meters (SLM).

ATTACHMENT B

Project Baseline Noise Monitoring Results

Site 2

Address: 22 Capella Garden, 9731 Capella Drive, Richmond, B.C.

Pre-Project Ambient Noise:

Site 2 is representative of fronting residences along Patterson Road, and is typical of residences along the Richmond portion of the Project corridor. Continuous noise monitoring was conducted at Site 2 for 24 hours. The microphone was located at the property line of Capella Garden adjacent residential Unit 22, 52 m south west of the centerline of Highway 99 (**Figure 1**). Site 2 had 180 degree exposure to Highway 99 traffic noise, the dominant noise source in this residential area. Secondary noise sources included YVR flights following the inbound flight path 700 m to the north. **Figure 2** depicts the noise levels in 15 minute intervals over the duration of the monitoring session. The pre-Project average day/night noise exposure to at Site 2 was estimated to be $L_{dn}(24)$ 72.2 dBA.

Proposed Improvements: Improvements along Highway 99 in the vicinity of this location include providing a dedicated transit/HOV lane in each direction and construction of a transit-only ramp at Bridgeport Road.

Figure 1 a) Photo of Microphone Site, and b) Aerial View of Noise Sampling Site

Figure 2 Noise Levels at Site 2 Measured in 15 Minute Intervals

Site 3

Address: 10168 Caithcart Road, Richmond, B.C.

Pre-Project Ambient Noise:

Site 3 is representative of residences along the western portion of the Caithcart Road residential area. Continuous noise monitoring was conducted at Site 3 for 24 hours. The microphone was located slightly above a 1.7 m high wooden fence located along the western property line of a standard sized city lot fronting onto St. Edwards Drive, the northbound offramp, and Highway 99 (**Figure 3**). Site 3 was set back 105 m from the Highway 99. Highway 99 traffic was the dominant noise source. The wooden fence provided noise shielding to the backyard area of 10168 Caithcart Road. However, the shielding was limited by noise scattering from the large evergreen canopy above the fence. Exposure to Highway 99 was slightly reduced by shielding provided by commercial buildings to the south. **Figure 4** depicts the noise levels in 15 minute intervals over the duration of the monitoring session. The pre-Project average day/night noise exposure at Site 3 was $L_{dn}(24)$ 69.7 dBA.

Proposed Improvements: Improvements along Highway 99 in the vicinity of this location include providing a dedicated transit/HOV lane in each direction and construction of a transit-only ramp at Bridgeport Road.

Figure 3 a) Photo of Microphone Site, and b) Aerial View of Noise Sampling Site
 November 4 - 5, 2013

Figure 4 Noise Levels at Site 3 Measured in 15 Minute Intervals

Site 4

Address: 9 Florence Estates, 10411 Hall Avenue, Richmond, B.C.

Pre-Project Ambient Noise:

Site 4 is representative of fronting residences along Hall Avenue. The microphone was located in a high hedge at a setback of 35 m from the centerline of Highway 99 (**Figure 5**). This microphone position was chosen to provide line-of-sight to Highway 99 over a varying height barrier located along the eastern property line. Continuous noise monitoring was conducted at Site 4 for 14-hours. The dominant noise source at Site 4 was Highway 99 traffic noise. **Figure 6** depicts the noise levels in 15 minute intervals in. The pre-Project average day/night noise exposure at Site 4 was estimated to be L_{dn} 72.0 dBA. The noise exposures at Site 2 and Site 4 are similar.

Proposed Improvements: Improvements to this section of Highway 99 including providing a dedicated transit/HOV lane in each direction.

Figure 5 a) Photo of Microphone Site (fence alignment perpendicular to centerline of Highway 99), and b) Aerial View of Noise Sampling Site

Figure 6 Noise Levels at Site 4 Measured in 15 Minute Intervals

Site 5

Address: 4591 Dallyn Road, Richmond, B.C.

Pre-Project Ambient Noise:

The microphone was located in a high hedge at a setback of 35 m from the centerline of Highway 99 (**Figure 7**). This microphone position was chosen to provide line-of-sight to Highway 99 over a varying height barrier located along the eastern property line. Continuous noise monitoring was conducted at Site 5 for 14-hours. The dominant noise source at Site 5 was Highway 99 traffic noise. **Figure 8** depicts noise levels in 15 minute intervals. The pre-Project average day/night noise exposure at Site 5 was $L_{dn}(22.3)$ 68.7 dBA.

Proposed Improvements: Improvements along Highway 99 in the vicinity of this location include providing a dedicated transit/HOV lane in each direction.

Figure 7 a) Photo of Microphone Site, and b) Aerial View of Noise Sampling Site
 November 5 - 6, 2013

Figure 8 Noise Levels at Site 5 Measured in 15 Minute Intervals

Site 6

Address: 11600 Dewsbury Drive, Richmond, B.C.

Pre-Project Ambient Noise:

The microphone was located just above the fence at a setback of 62 m from the centerline of Highway 99 (**Figure 9**). This microphone position was chosen to provide line-of-sight to Highway 99 over the fence located along the western property line. Continuous noise monitoring was conducted at Site 6 for 21-hours. The dominant noise source at Site 6 was Highway 99 traffic noise. **Figure 10** depicts the noise levels in 15 minute intervals. The pre-Project average day/night noise exposure at Site 6 was $L_{dn}(21)$ 74.1 dBA.

Proposed Improvements: Improvements along Highway 99 in the vicinity of this location include providing a dedicated transit/HOV lane in each direction.

Figure 9 a) Photo of Microphone Site, and b) Aerial View of Noise Sampling Site
 April 7 - 8, 2014

Figure 10 Noise Levels at Site 6 Measured in 15 Minute Intervals

Site 7

Address: 12260 Westminster Highway, Richmond, B.C.

Pre-Project Ambient Noise:

The microphone was located at a setback of 93 m from the centerline of Highway 99 (**Figure 11**). Site 7 is directly exposed to the Westminster Highway overpass eastbound lanes. Line-of-sight to Highway 99 is broken by the south bound onramp fill section. Continuous noise monitoring was conducted at Site 7 for 20 hours. The dominant noise source at Site 7 was Westminster Highway traffic noise. **Figure 12** depicts the noise levels in 15-minute intervals. The pre-Project average day/night noise exposure at Site 7 was $L_{dn}(21)$ 67.0 dBA.

Proposed Improvements: The existing Westminster Highway interchange will be upgraded.

Figure 11 a) Photo of Microphone Site, and b) Aerial View of Noise Sampling Site
 April 9, 2014

Figure 12 Noise Levels at Site 7 Measured in 15 Minute Intervals

Site 8

Address: 12250 Westminster Highway, Richmond, B.C.

Pre-Project Ambient Noise:

The microphone was located at the western edge of the property line at a setback of 115 m from the centerline of Highway 99 (**Figure 13**). Continuous noise monitoring was conducted at Site 8 for 24 hours. The dominant noise source at Site 8 was Highway 99 traffic noise. **Figure 14** depicts the noise levels in 15-minute intervals. The pre-Project average day/night noise exposure at Site 8 was L_{dn} 64.2 dBA.

Proposed Improvements: The existing Westminster Highway interchange will be upgraded.

Figure 13 a) Photo of Microphone Site, and b) Aerial View of Noise Sampling Site

Figure 14 Noise Levels at Site 8 Measured in 15 Minute Intervals

Site 9

Address: 12431 Blundell Road, Richmond, B.C.

Pre-Project Ambient Noise:

The microphone was located just above the fence with a setback of 73 m from the centerline of Highway 99 (**Figure 15**). Continuous noise monitoring was conducted at Site 9 for a total of 48 hours. The dominant noise source at Site 9 was Highway 99 traffic noise. **Figure 16** depicts the noise levels in 15 minute intervals for 29 to 30 Oct and 30 to 31 Oct, respectively. The pre-Project average day/night noise exposure at Site 9 was L_{dn} 72.5 dBA for October 29 to 30, and 70.4 dBA for October 30 to 31, 2013.

Proposed Improvements: The existing Blundell Road overpass will be upgraded.

Figure 18 Noise Levels at Site 10 Measured in 15 Minute Intervals

Site 11

Address: 10640 No. 5 Road, Richmond, B.C.

Pre-Project Ambient Noise:

The microphone was located adjacent the Highway 99 southbound exit to the Steveston Highway, and 100 m to the west of the centerline of Highway 99. This location is representative of the proposed façade of The Gardens - Phase 3 located an additional 15 m to the west (**Figure 19**). Continuous noise monitoring was conducted at Site 11 for 24 hours. The dominant noise source was Highway 99 traffic noise. **Figure 20** depicts noise levels in 15 minute intervals. The pre-Project average day/night noise exposure at Site 11 was $L_{dn}(24)$ 65.7 dBA.

Proposed Improvements: This section of Highway 99 includes the northern approach to the proposed new bridge replacing the Tunnel. The Steveston Highway interchange will be upgraded.

Figure 36 Noise Levels at Site 19 Measured in 15 Minute Intervals

Site 20

Address: 8640 Ladner Trunk Road, Delta, B.C.

Pre-Project Ambient Noise:

The microphone was located at a setback of 93 m from the centerline of Highway 99 (**Figure 37**). Site 20 is exposed to Highway 99 noise, and influenced by Ladner Trunk Road noise. Line-of-sight to Highway 99 is unbroken. The dominant noise source at Site 20 was Highway 99 noise. Continuous noise monitoring was conducted at Site 20 for 24 hours. **Figure 38** depicts noise levels in 15 minute intervals. The pre-Project average day/night noise exposure at Site 20 was $L_{dn}(24)$ 67.5 dBA.

Proposed Improvements: The existing Highway 99 alignment will remain unchanged. Additional lanes are proposed which could involve widening the section of Highway 99 between the Highway 17 connection, and Ladner Trunk Road and include providing a dedicated transit/HOV lane in each direction

ATTACHMENT C

Traffic Noise Prediction Methods

Prediction of the 2030 L_{dn} , L_d , and L_n

The relevant noise metrics for the atmospheric noise study include L_{dn} , L_d , and L_n . These three metrics were measured at all long-term monitoring noise sites and were estimated at short-term monitoring sites.

The forecast noise levels with Project for the year 2030 were predicted using either a baseline adjustment method or highway noise modelling software.

Baseline Adjustment Method for Estimating the 2030 L_{dn} , L_d , and L_n

The baseline adjustment method (BAM) is suitable for predicting future noise levels in situations where the highway geometry, existing and with Project, is simple. The BAM has been used to estimate effects of the Project on receptor exposures to operational (traffic) noise throughout most of the study area with the exception of the segment including the new bridge and its approaches. The BAM was then employed for all sites between Westminster Highway and Steveston Highway; between Highway 17A and Highway 17; and between Highway 17 and Highway 91.

The BAM is based largely on *Road and Rail Noise: Effects on Housing* (CMHC 1981), which provides a manual procedure for forecasting highway noise levels. This methodology can also be used to estimate project-related changes in noise levels by adjusting baseline noise levels to reflect future traffic growth and foreseeable changes in other highway parameters, as listed below. The procedure permits 24-hour average highway noise exposures to be predicted based on the following pre-Project and post-Project traffic parameters:

- Average daily traffic volume
- Heavy truck mix
- Posted speed
- Level-of-service
- Noise sensitive receptor setback distance from highway centreline
- Elevations of both highway and receptor relative to the surrounding ground surface
- Nature of the intervening ground surface – acoustically hard or soft

Using these input parameters, the 2030 24-hour equivalent sound level ($L_{eq}(24)$) at the receptor location may be estimated. Similarly, if one or more of these parameters is to be changed as a result of a proposed highway improvement project, then the effect(s) of the change(s) on a measured baseline $L_{eq}(24)$ can be predicted. Assuming the proportioning of traffic between the 15 daytime and nine nighttime hours does not change, the change in L_{dn} will be the same as the change in $L_{eq}(24)$.

As an example of the CMHC procedure, consider the hypothetical case in which a new lane is to be added on each side of an existing four-lane highway around a fixed centreline and, as a result, the total traffic volume will increase by 30%, heavy truck mix will increase from 5% to 8%, and the posted speed will increase from 80 km/h to 100 km/h. The $L_{eq}(24)$ at residences set back more than about 30 m from the highway would then be expected to increase by approximately 4.0 dBA (1.0 dBA from volume growth, 1 dBA from heavy truck mix growth, and 2 dBA from speed increase¹). Therefore, if the pre-Project noise level was, for example, L_{dn} 63 dBA, the post-Project level would be approximately L_{dn} 67 dBA.

Noise Modelling Software for Predicting the 2030 L_{dn} , L_d , and L_n

The new bridge that will replace the Tunnel involves a complex change from the existing horizontal and vertical alignment of Highway 99. The BAM approach is not capable of accurately predicting the effects of these changes on noise levels at the baseline noise monitoring sites. Therefore, for the extent of the new bridge and its approaches (i.e., from the Steveston Highway Interchange to the Highway 17A Interchange), the U.S. Federal Highway Administration (FHWA) Traffic Noise Model (TNM) Version 2.5 was used instead, and was run within DataKustiks' CadnaA Version 4.3.143 noise prediction software. The input parameters required for TNM are as follows:

- Proposed horizontal and vertical alignments of Highway 99
- 2030 annual average daily traffic volumes (AADT), and day/night traffic split
- Proposed posted speed (km/h) (light vehicles are assumed to run at posted speeds; heavy trucks are assumed to run at posted speeds on flat but at reduced speeds on grades)
- Anticipated distribution of traffic across the new 10-lane bridge

¹ These adjustments come from CMHC (Canadian Mortgage and Housing Corporation 1981. Road and Rail Noise: Effects on Housing, ISBN 0-662-11021-0.ftp://ftp.cmhc-schl.gc.ca/chic-ccdh/Research_Reports-Rapports_de_recherche/Older13/CA1%20MH110%2081R56_w.pdf)

- Proposed pavement type
- Setback distances from the new Bridge and approaches to noise receptors
- Nature of intervening ground (acoustically hard versus soft)
- Presence of noise-shielding elements, such as concrete roadside barrier (CRB) or bridge parapet
- TNM default weather conditions; calm winds and neutral atmosphere

The FHWA's TNM contains vehicle noise source reference data developed from North American vehicles, including heavy trucks with elevated exhaust stacks, as well as algorithms for generating the appropriate noise emissions from each highway segment based on volume, truck mix, speed, and grade. The noise emission data for heavy trucks are partitioned into two source zones — a lower zone that represents engine, drive train and tires; and a higher zone that represents exhaust stacks. This partitioning of noise source zones for heavy trucks is particularly important in terms of noise prediction accuracy when noise-shielding elements will be involved, such as the CRB and parapet that will run along outer edges of both the northbound and southbound lanes on the new Bridge and approaches. The TNM's split source height has the additional advantage of accurately representing truck noise emissions in evaluating the effectiveness of any roadside noise barriers that might be considered, should predicted noise levels due to the Project warrant mitigation consideration.

The TNM of the new bridge and its approaches is a three-dimensional model that incorporates the horizontal and vertical alignments, and the distribution of the forecast 2030 traffic flows across the five southbound and five northbound lanes. Each lane is assigned the appropriate daytime/nighttime traffic volumes and daytime/nighttime heavy truck mix. The noise emissions from the various traffic lanes are then propagated outward from the highway, over the edge of the bridge parapet, down to the quite widely distributed noise-sensitive receptors below, both to the east and west of the alignment.

Sound is only partially blocked when the line of sight between the source and the receptor is interrupted by a solid object such as a bridge parapet. Sound, particularly lower-frequency sound, diffracts around such objects and is attenuated (reduced in level) in the process, but not eliminated. The bridge parapet, enhanced by the 0.8 m high CRB located along the outer edge of the bridge deck, acts to reduce the levels of traffic noise reaching receptors near ground level, particularly for traffic in the centre lanes, well away from the bridge parapet. Modelling has shown that noise levels at these ground-level receptors would, in fact, be expected to be higher if the Project was not located on a high bridge, but rather was essentially at grade or on a causeway similar to the existing low bridge spanning Deas Slough. This is because,

in the ground level highway case, only a small amount of shielding would be provided by the 0.8 m CRB as it would shield tire noise only. Heavy truck engine and exhaust noise would receive little or no shielding in this situation.

A baseline (pre-Project) noise model can be calibrated against the traffic noise levels measured at certain locations. For this purpose, a baseline noise model was developed of the existing Highway 99 traffic over a limited portion of the study area. Calibration of the TNM then involved the comparison of predicted baseline noise levels at a suitable location with the baseline noise level measured at the same location. A suitable location is one that is fairly close to the highway (so that highway noise dominates overall noise levels), and has level ground conditions between it and the highway.

The traffic data used in the baseline model calibration are provided in **Table C2** to **Table C5**. 2013 AADT and heavy truck mix for Highway 99 was used, based on count station data and/or Equilibrie Intermodal; Modal Equilibrium 2 (EMME2), model projections. The intervening terrain between Highway 99 and residences was modelled using existing ground elevation contours.

Site 15 (12 River Woods, 6105 River Road, Delta; **Figures 27** and **28**, **Appendix B**) was chosen for model calibration since it is set back 70 m over flat terrain from the centerline of Highway 99, and its noise environment is dominated by highway traffic. The baseline traffic noise level was predicted at this site using 2013 traffic volumes and assuming a posted speed of 80 km/h.

The calibration was also sensitive to ground type. The default ground for TNM is grass. CadnaA provides a selectable ground absorption coefficient in the range of 0 (hard) to 1 (soft). A ground absorption coefficient of 0.5 was assumed representing medium ground (meadow grasses) over a propagation path length of typically 50 to 500 m.

The L_{dn} measured at site 15 in April 2014 was 68.4 dBA. The TNM baseline model of Highway 99, using the input parameters listed above, yielded L_{dn} 69.0 dBA. The resulting 0.5 dBA difference between measured and predicted baseline noise levels at site 15 is considered to represent acceptable agreement for purposes of the subsequent modelling of traffic noise levels with the Project. This minor deviation between the measured and modelled baseline L_{dn} is considered to be attributable, in part, to the effects of the traffic congestion that occurs in the northbound lanes during peak traffic periods.

The 2030 L_{dn} , L_d , and L_n

The BAM and TNM were used to forecast the 2030 L_{dn} , L_d , and L_n at the noise-sensitive locations (baseline monitoring sites) listed in **Table 8** and **Table 9** of the technical volume report. These forecasts accounted for anticipated traffic volume growth, heavy truck mix increases, alignment modifications, and other changes over the decade following Project completion, in accordance with the 2014 MOTI noise policy.

The Highway 99 alignment within the study area features five interchanges, or nodes, and six mainline segments (see **Table C1**). The traffic parameters (2013 and 2030 AADT, lane distribution, heavy truck mix, day/night split, posted speed, and level of service) can vary from one segment to the next.

Table C1 Highway 99 Segments for Assessment of Operational Noise

| Mainline Segments | Station Numbers |
|--|--|
| A - Bridgeport Road to Westminster Highway | 1a, 1, 2, 3, 4a, 4b, 4, 5, 6, and 7a |
| B - Westminster Highway to Steveston Highway | 7, 8, 9, 10, 10a, 10b, 10c, 11, and 13 |
| C - Steveston Highway to Highway 17A | 11a, 12, 12a, 14, 15, 15a, 15b, 15c, 16a, 16b, 17, 17a, 17b, 17c, and 18 |
| D - Highway 17A to Highway 17 | 19 |
| E - Highway 17 to Ladner Trunk Road | 20, 21, 22 |
| F – Ladner Trunk Road to Highway 91 | 20a, 23, 24, 24a |

The relevant traffic data for each of the six mainline segments of Highway 99 shown in **Table C1** are provided in **Tables C2 to C5**. The Ministry provided existing 2013 AADT and heavy truck mix. However, the 2013 volumes do not reflect the opening of Highway 17, which occurred in December, 2013. The future 2030 traffic data were provided by the Ministry Project team and are based on the EMME2 traffic volume model. The EMME2 2030 forecast provided the following for the mainline and on/off-ramps:

- AADT
- Lane distribution
- Heavy truck mix
- Day/night traffic split

The Ministry provided the 2013 posted and 2030 design speeds. The Project team provided the relevant future alignment information, namely, horizontal and vertical alignments and grades of the mainline and on/off-ramps. The pavement was assumed to be the average pavement type specified in the TNM. The intervening terrain between these roadway segments and residences was modelled using a composite digital terrain model which, within the Project footprint, superimposed the design ground on the existing ground.

Table C2 Existing and Future Traffic Data for Highway 99 (Segment A)

| Location | | Average Daily Traffic Volume AADT ¹ (vpd) | | Heavy Truck Mix | | Speeds (km/h) | |

Estimating Effects of Level of Service Improvement on Noise Levels

One of the objectives of the Project is improving the level of service provided to drivers. Currently, there is substantial congestion at the northbound and southbound Tunnel portals. The resulting reduced average vehicle speeds result in reduced overall traffic noise emissions. At speeds above about 30 km/h, overall traffic noise emissions decrease steadily with decreasing average vehicle speed by approximately 1.5 dBA per 10 km/h (US FHWA 2004).

Information on the existing level of service was available from three Ministry permanent count stations — one at each of the north and south Tunnel portals, and one just north of Westminster Highway. The data provided included the hourly traffic volumes and hourly speed profiles at Westminster Highway, Steveston Highway, and Highway 17A. This information characterized the diurnal traffic patterns around the Tunnel and permitted the hourly correction to the L_{eq} for traffic volume and speed. In some locations, and for some times of day, the congestion-related reductions in average vehicle speed are as much as 70 to 80 km/h (e.g., existing speeds of 20 to 30 km/h, and posted or free-flowing speeds of 90 to 100 km/h). For a traffic stream containing five per cent heavy trucks ², TNM predicts that traffic noise levels are minimized when average vehicle speed falls into the 30 to 35 km/h range. When speeds drop below 30 km/h, however, TNM predicts that overall noise emissions begin to increase again. The associated increases in noise levels due to the elimination of congestion may, for certain traffic movements at certain hours of the day, be as much as 8 dBA. This assumes that in the assessment horizon year 2030, Highway 99 traffic will be free-flowing and at or near posted speeds throughout the study area.

For noise-sensitive receptors in the vicinity of the new bridge, and for which TNM has been used to predict noise changes related to the Project (see technical volume, **Table 9**), there is no need to correct for the speed-related traffic noise effects described above, since they are addressed directly in the modelling process. Where changes related to the Project have been predicted using the BAM, however, it has been necessary to apply speed-related adjustments to account for the fact that, in the BAM, both existing and future traffic regimes are considered free-flowing, with average vehicle speeds equaling the posted speeds, as indicated in **Tables C2** through **C7**.

To quantify these adjustments, the Ministry's hourly speed profiles were combined with the 24-hour baseline hourly noise levels measured at the noise-sensitive receptor closest to each of the count stations. This process was executed separately for northbound and southbound lanes since the speed profiles for the two travel directions are not symmetrical. This process took into account a 10 dBA penalty for traffic noise between 22:00 and 07:00 hours (defined as nighttime in the 2014 MOTI noise policy) and yielded daily average baseline noise levels (L_{dn}) without the effects of traffic congestion. The BAM was then applied to these adjusted levels to forecast effects of the Project and arrive at the 2030 noise levels in terms of L_{dn} at the representative receptor locations.

² The Project team provided the truck mix data throughout the study area as derived from EMM2 modelling. Existing (2013 with SFPR) truck mixes range from approximately 3.5% to 5%.

ATTACHMENT D

Project Construction Noise

Scope and Description of Project Construction

The construction zone includes sections of the Project that reside within the Ministry right-of-way as summarized in **Table D1**. The scope of construction for the Project includes the components presented in **Table D2**.

Table D1 Project Segments for Construction Noise Modelling

| Project Segments | Station Numbers |
|--|---|
| A - Bridgeport Road to Westminster Highway | 1a, 1, 2, 3, 4a, 4b, 4, 5, 6, and 7a |
| B - Westminster Highway to Steveston Highway | 7, 8, 9, 10, 10a, 10b, 10c, 11, and 13 |
| C -Steveston Highway to Highway 17A | 11a,12, 12a, 14, 15, 15a, 15b, 15c, 16a, 16b, 17, 17a, 17b, 17c, and 18 |
| D - Highway 17A to Highway 17 | 19 |
| E - Highway 17 to Ladner Trunk Road | 20, 21, 22 |
| F – Ladner Trunk Roadto Highway 91 | 20a, 23, 24, 24a |

Table D2 Project Works and Activities that May Generate Atmospheric Noise

| Works | Activities |
|--|---|
| Westminster Highway interchange | Ramp relocation, interchange reconstruction |
| Overpass construction/replacement | Reconstruction |
| Steveston Highway interchange | Ramp relocation, interchange reconstruction |
| North approach ramp (Richmond) to new bridge | Hauling, grading, compacting, paving |
| New bridge | Pile driving, tower construction, deck replacement |
| Tunnel decommissioning | Sediment removal, diesel-powered pumps |
| S. bridge approach/River Road ramp (Delta) | Hauling, grading, compacting, paving |
| Highway 17A interchange | Ramp relocation, interchange reconstruction |
| Highway 99 mainline | Hauling, grading, compacting, paving, line painting |
| Highway 17 interchange | Ramp configuration |

The anticipated conceptual design construction elements and activities include the following:

- New bridge - Fraser River crossing
 - Clear-span bridge – no piers in river
 - Sections of bridge lifted into place from barge
 - Ground improvements required to address soft soils

- Traffic management during construction
- Deas Slough crossing
 - Sections of bridge deck lifted into place - no piers in Deas Slough
 - Ground improvements required to address soft soils
 - Ground improvements on edge of the slough
 - Traffic management during construction
- Tunnel decommissioning once the new bridge is operating
 - Remove sediment, sand and riprap protection layer above the six elements of the Tunnel
 - Remove concrete apron along submerged Tunnel sections
 - Remove sediment beneath the Tunnel elements to install cables
 - Lift the Tunnel elements with pontoons

Other construction activities in proximity to noise-sensitive receptors would occur at the eastward displacement of Highway 99 at Blundell Road, the Steveston Highway overpass and laydown area, and potentially at the Deas Slough barge access.

Construction Noise Model

Since the details of construction schedules and equipment lists will not be available until later in the design process, it has not been possible to conduct a specific assessment of the noise emissions to be expected during the construction phase of the Project. Therefore, in estimating potential construction noise exposures for the Project, a generic construction noise analysis has been adopted that was originally developed for the Sea-to-Sky Highway Improvement Project (STS project) and subsequently employed during the environmental impact assessment phases of the Port Mann Highway 1 and SFPR projects. Estimates based on the STS project have been adjusted according to anticipated construction activities that would apply to this Project.

In estimating potential outdoor noise exposures from major construction activities at noise-sensitive locations, the following factors were taken into account within the generic construction noise model:

- The distance from the construction noise source area to noise-sensitive receptors
- The various major roadway and/or structure construction activities that are expected to take place within each segment of the Project
- The time of day or night and duration (hours per day) of the major activities

- Types and numbers of pieces of heavy equipment anticipated in each major construction activity
- Rated or typical full-power noise emissions for each equipment type (noise level in dBA at a standard reference distance of 15 m)
- Representative usage factors for each equipment type (i.e. proportion of time operating at or near full power)
- Attenuation of construction noise levels with increasing setback distance from the roadway due to several effects (geometric spreading, atmospheric absorption and ground effect attenuation)

The overall equivalent sound levels (L_{eq}) predicted to be generated during active construction periods on the STS project are shown in **Table D3**. Note that the values shown are the average noise levels that would be expected to be produced at various setback distances from an active, 200 m-long construction zone due to the cumulative noise output of all active heavy construction equipment. The levels presented are those that would be expected if the intervening ground was acoustically soft (e.g., grass). **Table D3** may then be used to estimate the ranges of average unmitigated construction noise levels that may be experienced during active construction periods at various noise-sensitive locations within the Project.

The entries in **Table D3** represent the average noise levels that would be measured at the given distances from an active construction zone. These levels would then exist only as long as the construction activities continues. To express potential Project construction noise exposures in terms of daily average levels, such as $L_{eq}(24)$ and L_{dn} , it is necessary to know or assume the normal hours of work. It is assumed that the construction work will be primarily conducted during daytime working hours and that a double day-shift schedule would be followed (i.e., within the hours of 07:00 to 22:00). This would result in, at most, about 14 hours of active construction per day, assuming 0.5 hour per shift for breaks. It has been assumed that there will be a night shift with seven active hours of construction and one hour for breaks. The L_d would then be obtained by adjusting the entries by a factor of -0.3 dBA to account for the lack of any construction noise for one hour of the 15 hours of nominal daytime (i.e., the energy ratio, $10 \cdot \log(15/14) = 0.3$ dBA). The L_n would be obtained by adjusting the entries by a factor of -1.0 dBA to account for the lack of any construction noise for two hours per night (i.e., the energy ratio, $10 \cdot \log(9/7) = 1.0$ dB). The L_{dn} would be calculated by combining the following:

- $L_d - 0.3$ dBA.
- Nighttime $L_{eq}(7 \text{ hours}) + 10$ dBA during active construction.
- Nighttime $L_{eq}(2 \text{ hours}) + 10$ dBA during inactivity.

Table D3 Average (equivalent) construction noise levels outdoors at various setback distances from an active, 200 m-long, construction zone, over soft ground

| Major construction activity | Equivalent Noise Levels (dBA) at Various Setback Distances | | | | | | |
|-----------------------------|--|------|------|-------|-------|-------|-------|
| | 15 m | 30 m | 50 m | 100 m | 200 m | 400 m | 800 m |
| Clearing and grubbing | 82.5 | 78.0 | 74.5 | 69.0 | 60.5 | 51.0 | 39.5 |
| Excavation and hauling | 84.0 | 79.5 | 76.0 | 70.5 | 62.0 | 52.5 | 41.0 |
| Pile-driving | 83.0 | 78.5 | 75.0 | 69.5 | 61.0 | 51.5 | 40.0 |
| Retaining walls/Structures | 80.0 | 75.5 | 72.0 | 66.5 | 58.0 | 48.5 | 37.0 |
| Grading | 82.0 | 77.5 | 74.0 | 68.5 | 60.0 | 50.5 | 39.0 |
| Asphalt paving | 79.0 | 74.5 | 71.0 | 65.5 | 57.0 | 47.5 | 36.0 |

The average construction noise exposures presented in **Table D3** are considered somewhat conservative since they assume construction activities are essentially continuous throughout the working hours. In reality, slowdowns and stoppages in construction activity are likely to occur from time to time. The duration of the various phases of construction will also vary considerably, from a few weeks for clearing, to a few months for grading, to three or four weeks for paving, and approximately two years for the new bridge.

Potential Noise Effects Associated with Interchange Upgrades

The Project will include the general construction activities provided in **Table D3** that would be associated with the upgrading of interchanges in the following locations:

- Blundell Road (Segment B)
- Highway 99/Steveston Highway Interchange (Segment C)

These locations are indicated by a construction zone polygon for the relevant noise sensitive receptor(s).

In addition, at this preliminary stage of the Project, construction sequencing details and optimal routes for the detouring of local traffic around active construction zones have not yet been developed. However, most detouring is expected to occur away from residential areas or be contained within the highway right-of-way.

Pile-driving Noise

During construction of the new bridge, residences within the study area Segment C may be exposed to noise in addition to the levels summarized in **Table D3**. These noise exposures will be associated with bridge foundation and structural activities which, with the exception of for pile

driving, can not be estimated until the construction methods to be employed and construction sequencing details are known.

Pile driving will be carried out in the Bridge construction zone and along the north and south bridge approaches in the following locations:

- North and south of Rice Mill Road
- South shore of Fraser River
- South abutment of the Deas Slough Bridge
- Near the River Woods residential community
- South bound off-ramp at River Road

Where appropriate, these locations are indicated by a construction zone polygon for the relevant noise sensitive receptor(s).

A model was created to predict noise levels (equivalent sound levels during active piling) at noise-sensitive receptors from pile driving impacts. Pile-driving activities were modelled as point sources of sound, and the propagation of pile-driving noise into the community was modelled using the *International Standards Organization 1996, ISO-9613(2), Acoustics - Attenuation of sound during propagation outdoors* (ISO 1996). Pile-driving on the Project is anticipated to involve steel pipe piles driven by a diesel hammer. The sound emission of L_w 132 dBA to be expected from such activities were provided by *Technical Memorandum on the Noise from Percussive Piling*, Hong Kong (EPD 1997). The pile-driving noise source was positioned at the various pile driving sites within the noise model, and the average pile driving noise levels at the relevant noise-sensitive receptors were calculated.

Construction Noise Model Results

The results from the construction noise estimation throughout the entire study area and the pile-driving noise and vibration predictions for the relevant receptor locations adjacent the Tunnel, north approach, and south approach are summarized in **Table D4**. For a given receptor, the ranges of levels correspond to the lowest noise level from the most distant piling site to the highest levels from the closest piling site to the relevant receptor site.

Table D4 Baseline Noise Levels and Construction Noise Levels Estimated at Noise Receptor Sites

| Site # | Noise-Sensitive Receptor Location | Land Use | Baseline (2013 - 2014) Noise Levels (dBA) | | | Construction Noise Levels (dBA) | | | | | | Active Pile Driving Noise Level, L_{eq} (dBA) | |

FRASER RIVER SALT WEDGE MODELLING

Technical Volume

December 9, 2015

FILE: V13203162

George Massey Tunnel Replacement Project

This report has been produced for the Ministry of Transportation and Infrastructure regarding the George Massey Tunnel Replacement Project.

Subject: Modelling Study to Investigate the Impact of Removal of the George Massey Tunnel on the Salt Wedge [ISSUED FOR USE]

1.0 INTRODUCTION

The potential effect of the proposed removal of the George Massey Tunnel (Tunnel) on the hydrodynamics and the behaviour of the salt wedge in the Fraser River was evaluated using the proprietary three-dimensional hydrodynamic model, H3D.

Two cases were examined in this study: 1) the existing case with the Tunnel in place, and 2) the case without the Tunnel. The top of the Tunnel is at a depth approximately 12-13 m below geodetic datum and is slightly proud of the surrounding river bottom in the deepest part of the channel (Figure 1.1). For these simulations, it is assumed that after the Tunnel is removed or decommissioned, the river bathymetry will return to its natural configuration. Figure 1.2 shows the smoothed bathymetry in the river without the Tunnel, used as the initial case for modelling.

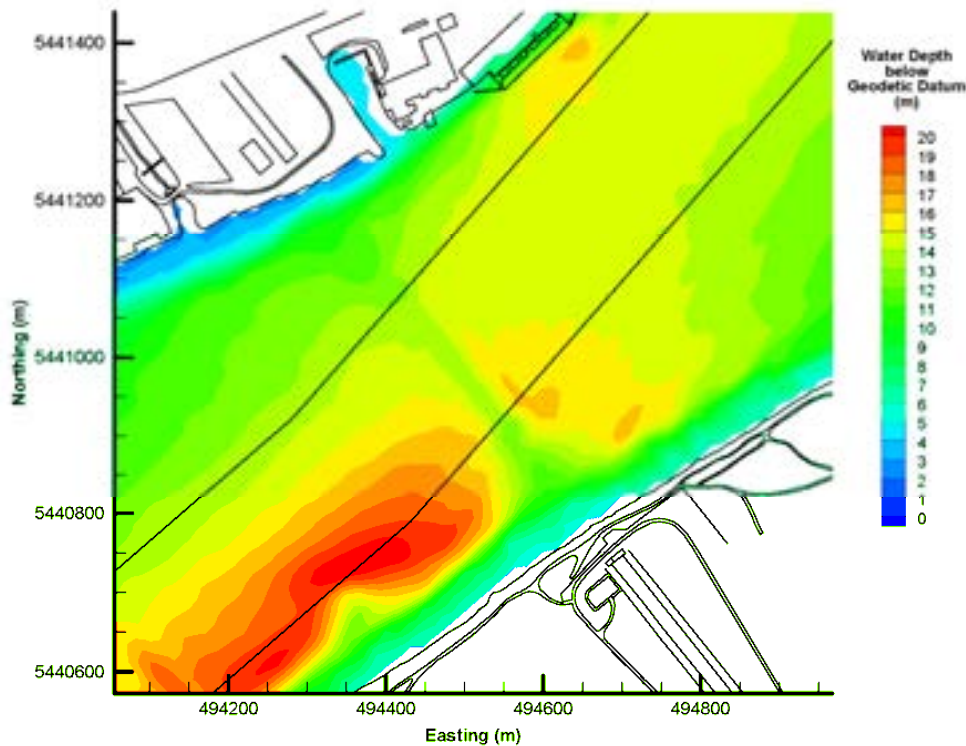

Figure 1.1: Existing Bathymetry near the George Massey Tunnel

Figure 1.2: “Smoothed” Bathymetry without the Massey Tunnel

The lower reach of the Fraser River is an estuary with outflowing fresh river water on top of the saltier water intruding from the Strait of Georgia at the bottom, thereby forming a salt wedge. The behaviour of the salt wedge strongly depends on the tide and river flow: the salt wedge advances and retreats daily in accordance with the daily tidal pattern, while the seasonally-varying upstream extent of the salt wedge excursion depends on the flow rate in the Fraser River. Tidal characteristics in the river are that at high water, currents in the river are generally small, and become directed in the downstream direction as the water level falls, forming an ebb tide condition. Outflow velocities reach their peak values somewhat before low water, then start to decrease and then change to an up-river, flooding state on the rising tide.

During an ebbing tide, velocities in the river increases until about the time of low water, pushing the salt wedge downstream, and out of the river during high flows. On the other hand, during a flood tide the velocity changes to an upstream flow, offering less resistance to the upstream advancement the salt wedge, thereby allowing the salt wedge to migrate upstream. During the freshet period, the salt wedge retreats offshore of Sand Heads on the ebb tide and advances just past Steveston Island on the flood tide; whereas in the low flow period, it retreats to Steveston Island on the ebb tide, but can advance as far as Annacis Island (Thomson, 1981) on the flood tide.

The main interest regarding the salt wedge as identified by stakeholders is that removal of the Tunnel and the subsequent change of the bathymetry in the vicinity of the Tunnel alignment could provide an easier pathway for the salt wedge to migrate upstream, especially during low flow periods, and thereby reduce the period of time when low-salinity water is available for irrigation purposes. At present, the water intake of greatest interest, located just upstream of Tilbury Island, withdraws water from the Fraser River to supply nearby farmlands for agriculture and harvesting purposes, but only operates in the time windows during which the salt wedge is located sufficiently downstream from the intake location that the water being withdrawn meets an appropriate salinity criterion. Salinity

sensitivity in crops, expressed in terms of conductivity, starts at approximately 700 microsiemens per centimeter, or 700 $\mu\text{S}/\text{cm}$ and the salinity sensor at the No.6 Road pump station was set at 500 $\mu\text{S}/\text{cm}$ (from an article by Matthew Burrows). Water with salinity higher than the criterion value has the potential to cause damage to agricultural products and soil where it is applicable. In this study, the conductivity criterion value of 400 $\mu\text{S}/\text{cm}$ (0.34 parts per thousand (ppt) salinity) is used which is the threshold value for cranberry irrigation.

This report first presents the numerical model, and then provides validation data, based on a comparison of computed salinities versus those collected by a sensor at the intake.

Then key salinity parameters, include salinity levels, location of the salt wedge toe, and daily periods of water suitable for irrigation, with and without the Tunnel in place, are then extracted from model output and compared, in order to quantify the effect of removal of the Tunnel.

2.0 HYDRODYNAMIC MODELLING

2.1 Hydrodynamic Circulation Model

A detailed technical description of H3D is attached in Appendix A. The following is a brief summary.

H3D is a three-dimensional time-stepping numerical model which computes the three components of velocity (u, v, w) on a regular grid in three dimensions (x, y, z), as well as scalar fields such as salinity, temperature and contaminant concentrations. The model uses the Arakawa C-grid (Arakawa and Lamb, 1977) in space, and uses a two level semi-implicit scheme in the time domain.

H3D is an implementation of the numerical model developed by Backhaus (1983; 1985) which has had numerous applications to the European continental shelf, (Duwe et al., 1983; Backhaus and Meir Reimer, 1983), Arctic waters (Kampf and Backhaus, 1999; Backhaus and Kampf, 1999) and deep estuarine waters, (Stronach et al., 1993). Locally, H3D has been used to model the temperature structure of Okanagan Lake (Stronach et al., 2002), the transport of scalar contaminants in Okanagan Lake, (Wang and Stronach, 2005), sediment movement and scour / deposition in the Fraser River (published document), circulation and wave propagation in Seymour and Capilano dams, and salinity movement in the lower Fraser River. H3D forms the basis of the model developed by Saucier and co-workers for the Gulf of St. Lawrence (Saucier et al., 2003), and has been applied to the Gulf of Mexico (Rego et al., 2010).

2.2 Model Implementation

Study of the details of the hydrodynamics requires model nesting to better resolve small scale processes at and near the location of interest. The model used for this study operates in a double-nested configuration, shown in Figure 2.1.

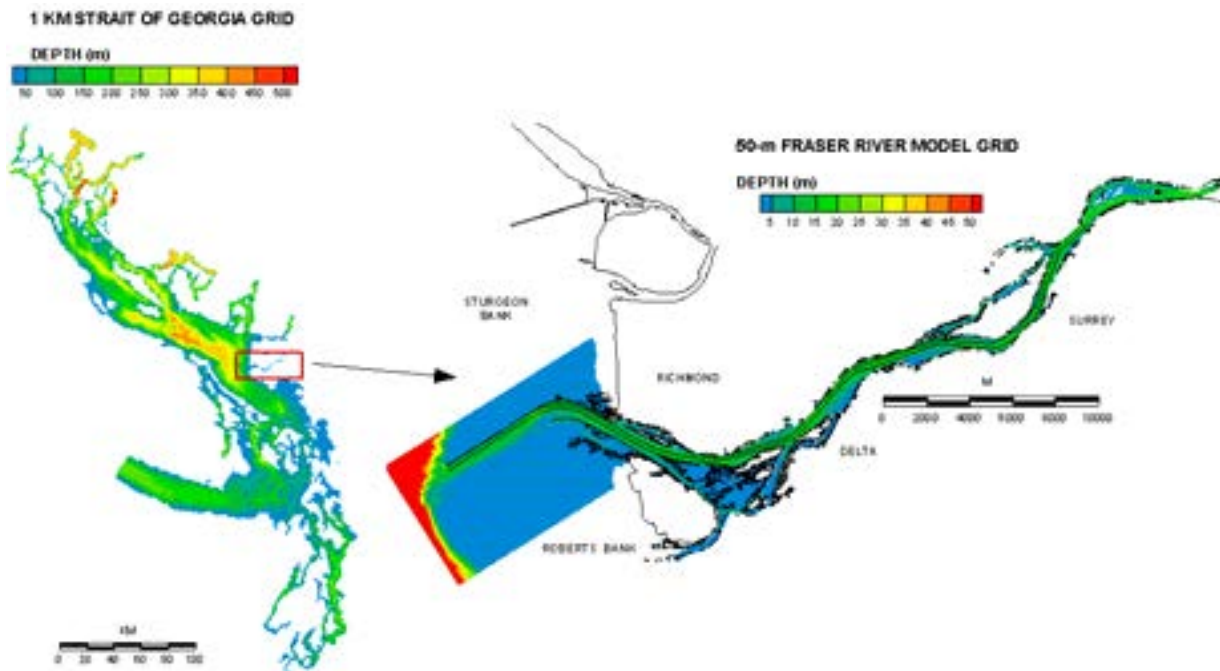

Figure 2.1: Model Nesting of Strait of Georgia and Fraser River Grids

The investigation of the behaviour of the salt wedge is done with a nominally 50-m resolution curvilinear model that spans the lower 41 km of the Fraser River, from Sand Heads to Port Mann Bridge. The model uses 50 m resolution in the along-channel direction, and 20 m in the cross-channel direction. This 50-m resolution model is in turn embedded within a nominally 1-km resolution model of the entire Strait of Georgia (SOG).

Both models simulate tidal, wind-driven and density-driven currents. Water level, velocity components and any scalar quantities output from the coarse grid model are passed on along the boundaries of the fine grid model and used to drive the finer-scale implementation of H3D. The fine-grid implementation provides the details of the effect of small-scale spatial variability in shorelines, depths and structures such as the tunnel cover.

The 1-km SOG model, driven by wind and density as well as tidal conditions along its open boundaries bordering the northern entrance to the Strait of Georgia and the western entrances to Juan de Fuca Strait includes a coarse representation of the Fraser River, extending upstream to km 41, with separate channels for the North Arm, the South Arm and Canoe Pass. At km 41, upstream of all salt wedge penetration, the model is dynamically coupled to a one-dimensional model of the Fraser River, extending to Hope. Tidal conditions are specified along the open boundaries of the 1-km SOG model.

The 50-m lower Fraser River model is driven at its upstream end by a flow boundary condition provided by the same dynamically-coupled one-dimensional model of the Fraser River that was also used for the 1-km model. At the downstream end, water levels and density profiles are obtained from the 1-km grid model, spatially interpolated from those cells of the 1-km grid model that correspond to the boundaries of the lower Fraser model.

The year 2011 was chosen for the modelling study as this is the year when bathymetry data collected from a bank-to-bank survey, from which the 50-m Fraser River model grid was constructed, is available; thus, the Fraser River flow rate in 2011 was used to drive the upstream boundary of the river model. The flow rate at the upstream boundary of the model is the combination of the flow rate at Hope and the estimated runoffs that report to the river downstream of Hope and upstream of Port Mann Bridge. Figure 2.2 shows the river flow rate at Hope in the year 2011. The model was run through the latter part of the fall season and beginning of winter season, from

November to January, when the flow rate at the Fraser River is low and the ability to withdraw freshwater from the river for harvesting is critical.

Figure 2.2: Fraser River Flow Rate at Hope in 2011

2.3 Model Validation

The model is validated against water level recorded at New Westminster, and against salinity data collected by a sensor installed at the intake near 8081 River Road, Delta. Data from a sensor that was mounted at 2 m depth from a floating platform is used for the comparison. Figure 2.3 shows comparison of salinity between observed and modelled values from November 3rd to 23rd. Also included in the figure are observed and modelled water levels for the same time period. Black lines show modelled values and red lines show observed values. Since the conductivity sensor cuts off at 5,500 $\mu\text{S}/\text{cm}$, the model results were similarly cut-off to facilitate comparison.

Figure 2.3: Comparison of Observed and Modelled Water Level and Salinity in the Fraser River

The model generally performs well predicting the trend of salinity and its variability on a daily time scale. In fact, the modelled salinities are frequently higher than observed, indicating that the model is conservative: it will under-predict the availability of water suitable for irrigation. However, the water intake is situated in a shallow area where complex processes controlling the movement of stratified flow might have contributed to the observed high variability and, sometimes, unpredictability in salinity at the intake. For example, the model almost always predicts an elevation of salinity during high tides when river flow is comparatively slower and water level in the river higher (for example, on November 7th); however, the sensor at the intake did not always detect such a salinity signal.

This behaviour can be partly understood by considering Figure 2.4, showing the map of salinity at the 2-m depth, on Nov 11 at 7 am, where the modelled result appears to deviate the most from the observed value. It can be seen that there is a high degree of spatial variability in the salinity field (at 2 m depth) in the vicinity of the intake. Salinity can vary from 3.5 ppt (4,500 $\mu\text{S/cm}$) to more than 5.0 ppt (6,500 $\mu\text{S/cm}$) near the intake in a matter of metres. Further analysis of model output demonstrates that there are two mechanisms for saline water to intrude onto the relatively shallow shelf on which the intake is located: either a selective withdrawal process, whereby saltier water is drawn up onto the bench from the adjacent deeper water (on both ebb and flood), or a process whereby the toe of the salt wedge rises to the surface upstream of the bench and then falls back partially onto the bench on the ebb tide.

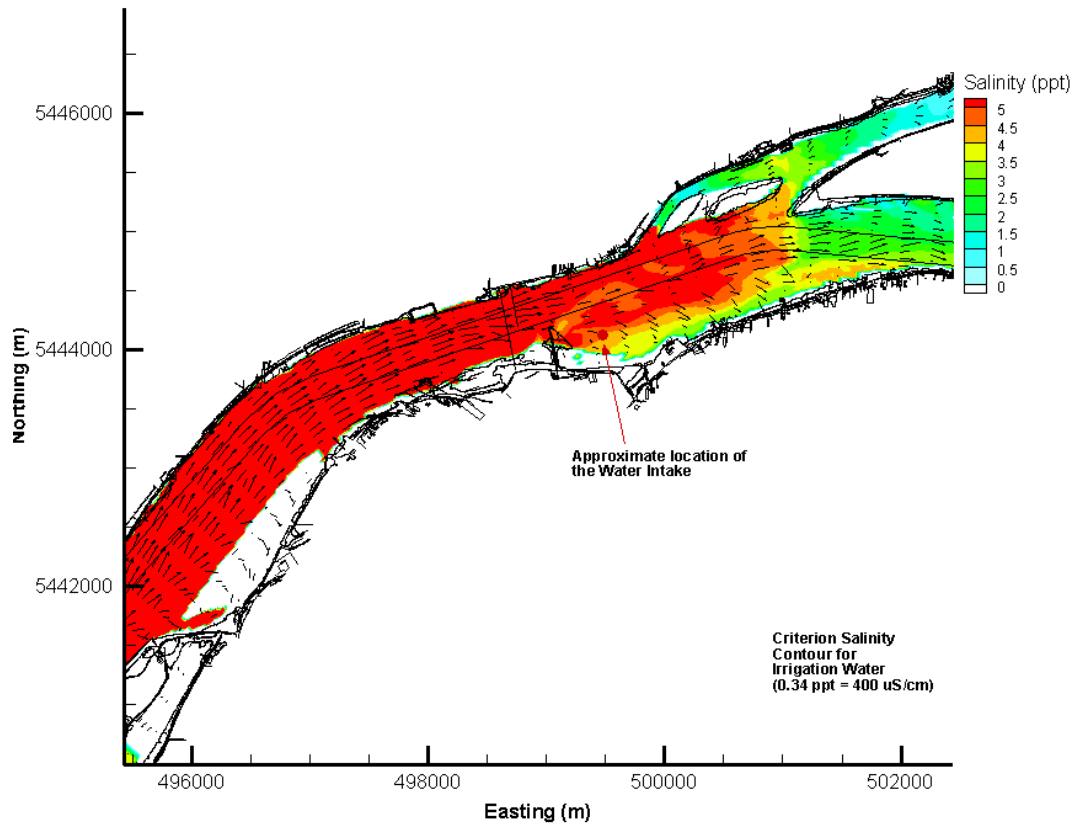

Figure 2.4: Snapshot of Salinity Contour at Intake Depth of 2m on November 11 at 7 am

Beside direct comparison of observed and modelled salinity, model validation can be considered from the perspective of water availability, which describes the onset and offset of salinity intrusion at the water intake and the time window within which river water can be safely withdrawn under the criterion salinity value of 0.35 ppt or 400 $\mu\text{S}/\text{cm}$. Figure 2.5 below compares the observed and modelled number of available hours per running 24 hours. The red line represents the observation and the black line represents the model results. The model, even though more conservative in general, was able to predict the overall trend in availability. Only a short period of record is presented, to facilitate visual comparison.

Figure 2.4: Comparison of Modelled and Observed Available Water Withdrawal Hours in November

The model, even though more conservative in general, was able to predict the overall trend in availability. The average number of hours available for water withdrawal in November is 14 hours per day based on observed salinity data, and 10 hours per day for the modelled case.

3.0 IMPACT OF TUNNEL REMOVAL

The hydrodynamic model simulations were run for the cases with and without the Tunnel. Although the model simulations presented in Section 2 did not always agree in detail with observations, the general characteristics are well-reproduced, and it is assumed that the differences in river hydrodynamics, with and without the Tunnel, will be captured by the model.

The effects of the absence of the Tunnel on the advancement of the salt wedge and on the salinity of the river water at the intake were assessed by comparing time-series of the salinity values at the water intake, as well as by comparing maps of salinity contours near the project location in the Fraser River. In this study, the focus is on the salt wedge behaviour during high tide periods, when the salt wedge migrates the furthest upstream.

This study focuses on the period between November and January during which the river flow decreases to a point where the salt wedge begins to exert effects on salinity in the water at the intake. The salt wedge remains mostly downstream of the Tunnel until November when the flow rate in the Fraser River drops to below 2,000 m³/s. The effects of the salt wedge become apparent during flood tide when the water level in the river is increasing and the flow speed is decreasing. Figure 3.1 shows the model results in terms of a time-series of salinity in mid-November at the intake. The black line represents the salinity at the intake for the case with Tunnel, and the green line

represents the case without the Tunnel, while the dotted blue line represents the salinity criterion for irrigation at 0.34 ppt(400 μ S/cm). Note the salinity difference between the two cases ranges between -0.1 ppt and 0.38 ppt, and, for most of the time, the absolute difference is less than 0.15 ppt.

The model was run continuously from November to January. Model results over only several tidal cycles were shown in the figures, however, to better illustrate visually the minute difference in the modelled salinity between the cases with and without the tunnel during the time of interest.

Figure 3.1: Modelled Intake Level Salinity at the Water Intake – November

Importantly, the modelling shows that at the location of the water intake, there is small difference between the salinity behaviour, in relative to the total salinity signal, with or without the Tunnel. The Root Mean Square (RMS) for the salinity signal is 1.36 ppt(1,760 μ S/cm), while the RMS of the salinity difference between the two cases is 0.11 ppt(143 μ S/cm), representing approximate 8% of the total salinity signal. The difference in salinity is greatest when salinities are high, and the water is unsuitable for irrigation.

Figure 3.2 shows, for the with-Tunnel case, a contour map of the salinity at the depth of the intake in the reach from the Tunnel to the water intake on November 13, 10 am during a high tide. Also included in the figure is an inset graph with the predicted (green line) and observed (black line) water levels at New Westminster; the blue and red lines represent the record high (4.66 m above CD) and low (0.42 m below CD) water levels measured at the location. Figure 3.3 shows the corresponding longitudinal sectional plot of salinity from Sand Heads (Km 0) to Annacis Island (Km 28). Figure 3.3 illustrates the upstream advance of the saline water, and that, consistent with Figure 3.2, surface salinities are around 2-3 ppt at the intake. Similarly, Figures 3.4 and 3.5 show the salinity contours for the without-Tunnel case. Figure 3.6 illustrates the two sets of plan view contours overlaid on one another to better illustrate the effect of the Tunnel removal on the salt wedge.

Figure 3.2: With Tunnel: Salinity Contour at Intake Level at High Tide, Nov 13, 2011 10:00 am

Figure 3.3: With Tunnel: Along-channel Salinity Contour at High Tide, Nov 13, 2011 10:00 am

Figure 3.4: Without Tunnel: Salinity Contour at Intake Level at High Tide, Nov 13, 2011 10:00 am

Figure 3.5: Without Tunnel: Along-channel Salinity Contour at High Tide, Nov 13, 2011 10:00 am

November 13, 10am; Near Daily Maximum Salt Wedge Excursion; Flow Rate = 1,800 m³/s

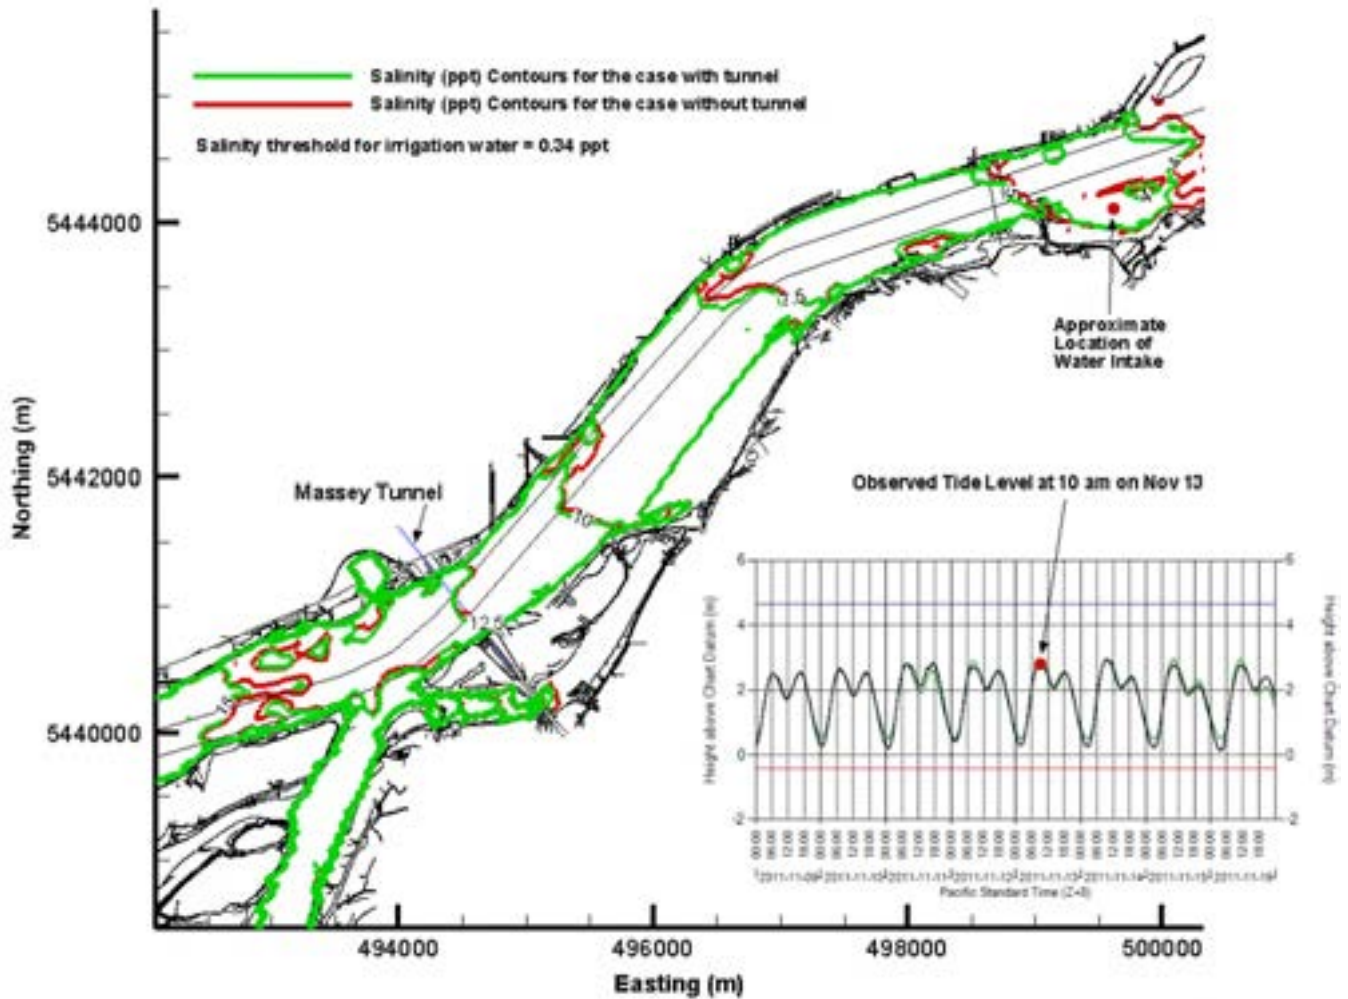

Figure 3.6: Overlaid Salinity Contours at Intake Level at High Tide, Nov 13, 2011 10:00 am

Figure 3.6 clearly indicates that the difference in the salt wedge behaviour between the two cases is generally small. The salt wedge without the Tunnel advances slightly further than in the case when the Tunnel is in place. The difference in salinity diminishes from downstream to upstream and there is only small difference in salinity at the location of the water intake (as illustrated in Figure 3.1).

Figures 3.7 and Figures 3.8 show similar time-series graphs for salinity at the water intake, but in December and January, respectively. Figure 3.9 and Figure 3.10 illustrate the overlaid salinity contour plots for December and January, respectively.

Figure 3.7: Modelled Intake Level Salinity at the Water Intake – December

Figure 3.8: Time Series Modelled Salinity at the Water Intake – January

Figures 3.7 and 3.8 indicate that, similar to November, the difference in salinity is insignificant at the intake between the cases with and without the Tunnel. The RMS of the salinity difference is 0.04 ppt (57 $\mu\text{s/cm}$) for December, while the corresponding RMS for the salinity signal is 2.27 ppt (2,930 $\mu\text{s/cm}$), representing less than 2% of the total signal.

For January, the RMS of the salinity difference is 0.20 ppt (259 $\mu\text{S/cm}$), while the corresponding RMS for the salinity signal is 1.70 ppt or 2,200 $\mu\text{s/cm}$, representing approximately 12% of the total signal. The difference in salinity is rather large compared to the total signal; however, the largest salinity difference occurs during high tides when salinity reaches its peak, and the water is unsuitable for irrigation. Salinity, for the most part, remains very similar between the two cases. The difference in peak salinity value and the time window within which the salinity value exceeds the criterion salinity value is also insignificant.

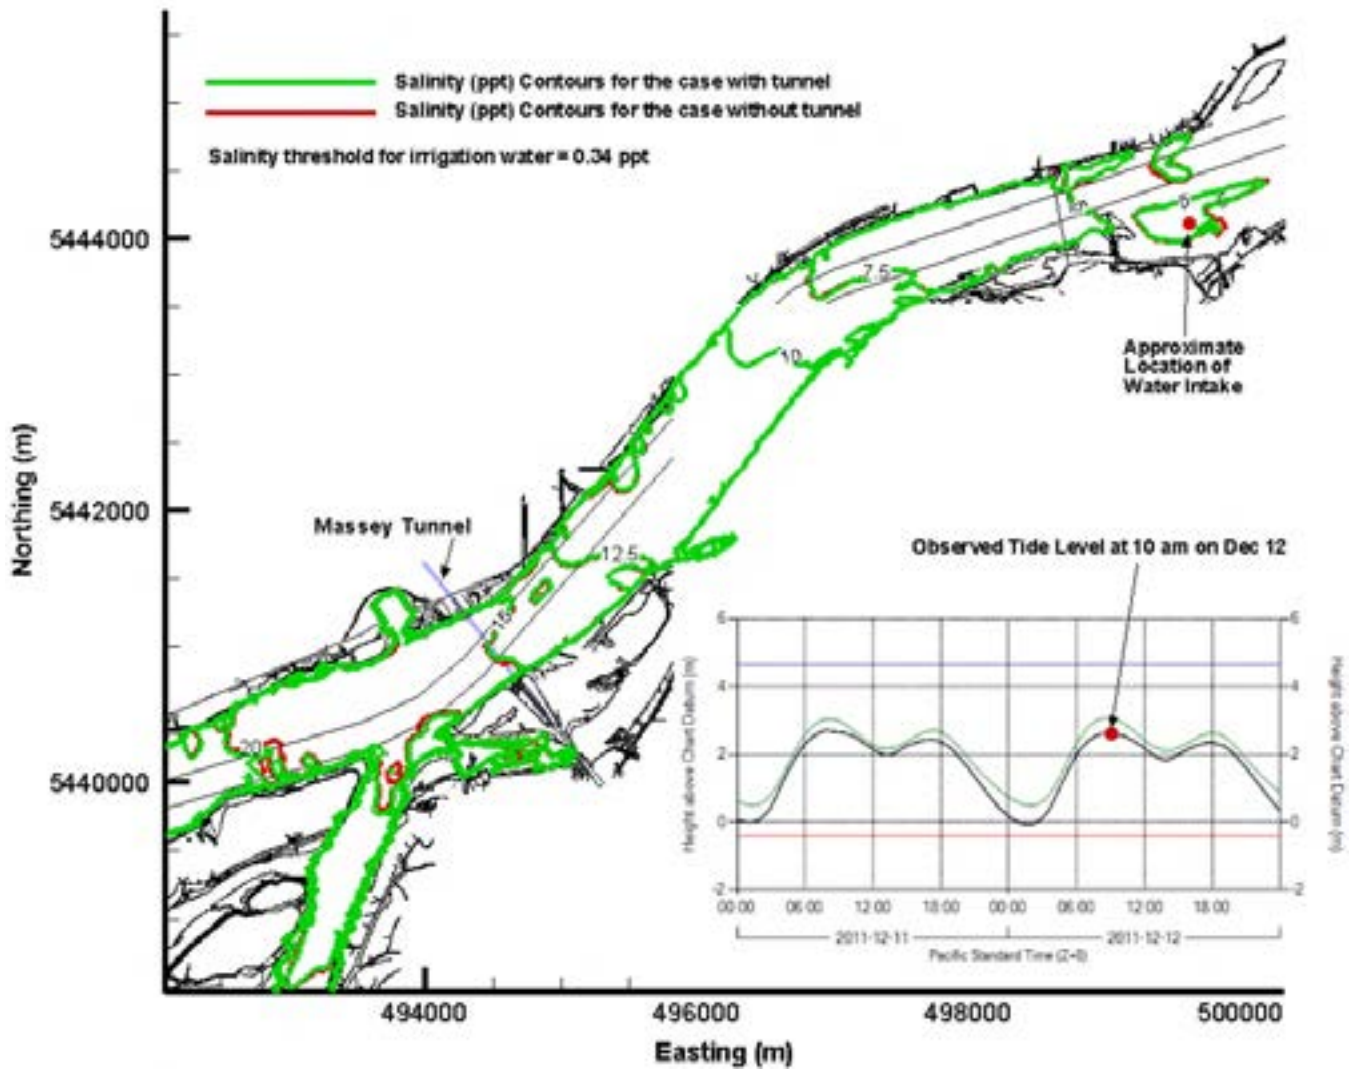

Figure 3.9: Overlaid Salinity Contours at Intake Level High Tide, December 12, 2011 10:00 am

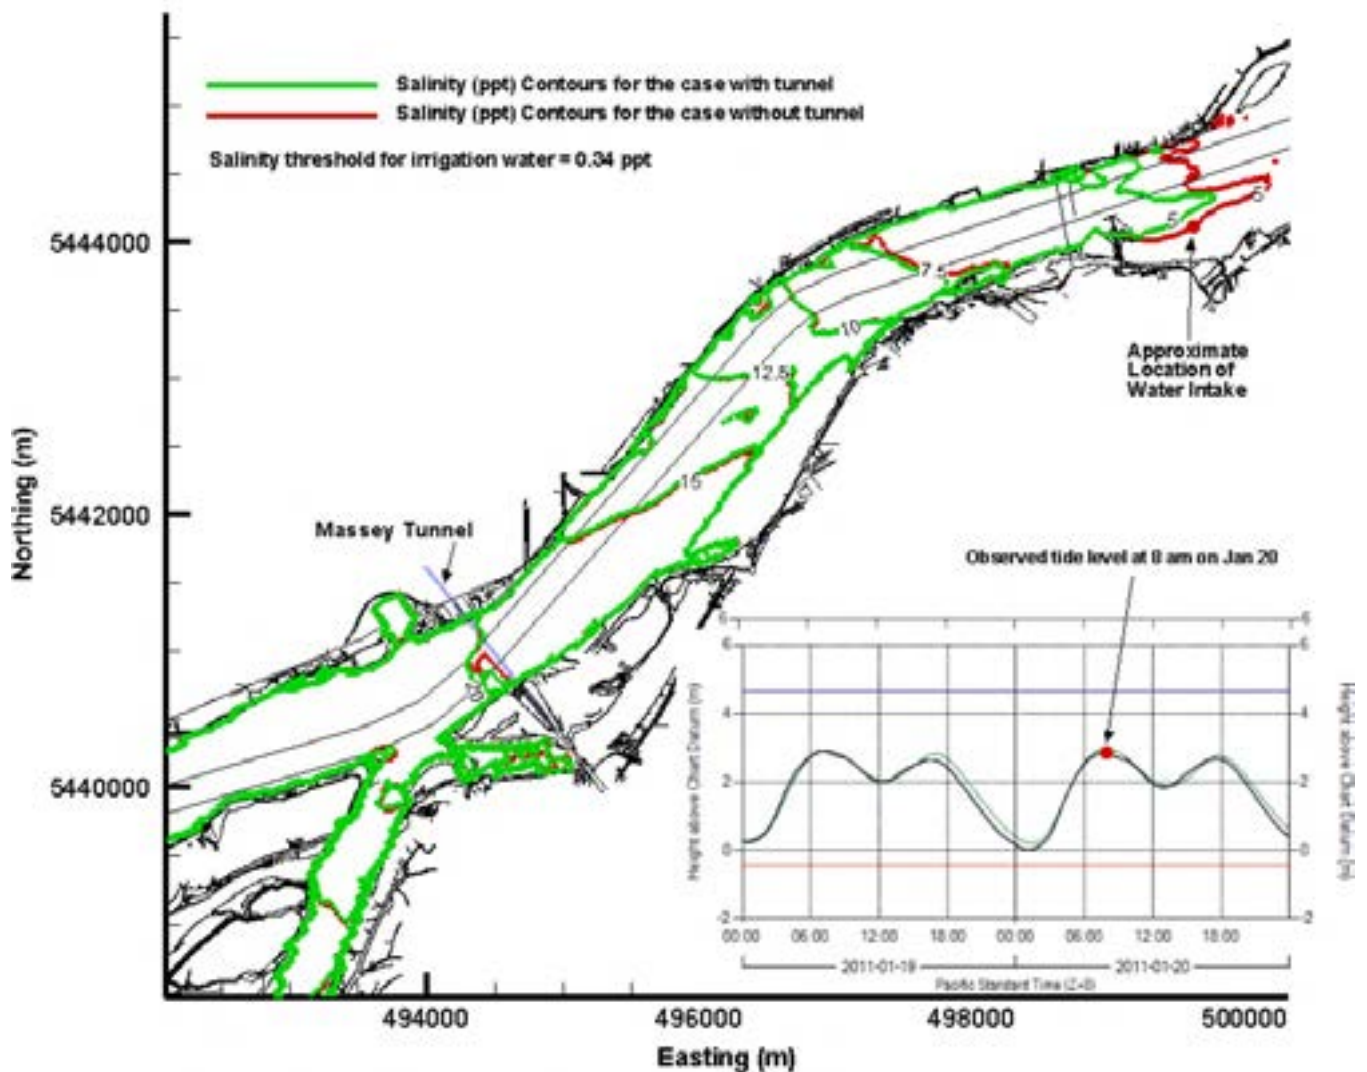

Figure 3.10: Overlaid Salinity Contours at Intake Level at High Tide, January 20, 2011 8:00 am

Figures 3.9 and 3.10 show that the extent of the salt wedge, as in November, behaves similarly between the cases with and without the Tunnel as can be seen by the largely overlapping salinity contours; the model does indicate a further advancement of the salt wedge when the Tunnel is removed as salinity contours can be found at locations mostly less than 50 m upstream in the case without the Tunnel

The small difference in the behaviour of the salt wedge in the pre- and post-removal cases is not unexpected. In the deepest part of the channel in which the salt wedge travels, the cross-channel ridge along the Tunnel alignment bounded by upstream and downstream scour degradation gives the impression that the Tunnel is proud of the surrounding river bottom to a similar height as that of the dynamic sand dunes formed in this part of the river. Figure 3.11 is a graphical excerpt from a 1995 report by Hay & Company (Hayco, 1995), showing the along-channel river bottom from the bathymetry survey in June of 1989 upstream of the tunnel (Massey Tunnel at km 18) and downstream of the intake at 8081 River Road (Intake at km 24). The x-axis is chainage distance measured from Sand Heads and y-axis is water depth. The natural variability of the river bottom in this area is a similar magnitude of, if not bigger than, the bottom associated with the presence of the Tunnel.

Figure 3.11: Bathymetry of Fraser River at Tilbury Bend upstream of the Tunnel (km 18) and downstream of the Intake (km 24) in June 1989

The river bottom along the Tunnel alignment, although not a migrating feature like dunes on the river bed, can be seen as one of these bottom elements in the river and thus, if considered individually, plays a very minor role in dictating the overall salt wedge behaviour.

4.0 CONCLUSIONS

The effects of the Tunnel removal on the hydrodynamics and salt wedge are summarized as follows:

- The proposed removal of the Tunnel will not affect the behaviour of the salt wedge.
- The effects of the Tunnel removal on the salt wedge diminishes in the upstream direction. While the salinity at the Tunnel alignment, for the case without the Tunnel, is slightly higher than that with the Tunnel, the time window during which the salinity in the water is higher than the criterion value is almost identical for the two cases at the location of the water intake.

The Tunnel does not act like a dam, which would have impeded the motion of water and the salt wedge in the river. The bathymetry footprint of the Tunnel is of no greater height and scale than the existing bathymetry features such as bed waves along other parts of the river.

5.0 CLOSURE

This report will be undertaken subject to the attached General Conditions, which will be incorporated into the report.

We trust this report meets your present requirements. If you have any questions or comments, please contact the undersigned.

APPENDIX A

H3D TECHNICAL DESCRIPTION

APPENDIX A: H3D TECHNICAL DESCRIPTION

1.0 INTRODUCTION

H3D is an implementation of the numerical model developed by Backhaus (1983; 1985) which has had numerous applications to the European continental shelf, (Duwe et al., 1983; Backhaus and Meir Reimer, 1983), Arctic waters (Kampf and Backhaus, 1999; Backhaus and Kampf, 1999) and deep estuarine waters, (Stronach et al., 1993). Locally, H3D has been used to model the temperature structure of Okanagan Lake (Stronach et al., 2002), the transport of scalar contaminants in Okanagan Lake, (Wang and Stronach, 2005), sediment movement and scour / deposition in the Fraser River, circulation and wave propagation in Seymour and Capilano dams, and salinity movement in the lower Fraser River. H3D forms the basis of the model developed by Saucier and co-workers for the Gulf of St. Lawrence (Saucier et al., 2003), and has been applied to the Gulf of Mexico (Rego et al., 2010). H3D and its hydrocarbon transport and weathering module have been used in three recent environmental assessment applications currently before the appropriate regulatory agencies. H3D was used to simulate an existing and proposed reservoir for BC Hydro's Site C Clean Energy Project. Temperature, ice cover, and sedimentation characteristics of the proposed reservoir were predicted, supported by model validations in existing Dinosaur Reservoir. Two reports are available at the provincial Environmental Assessment Office. H3D was used to do oil spill modelling for the environmental and engineering assessments for the proposed Gateway project involving oil shipment out of Kitimat. The modelling work forms part of the information package submitted to the National Energy Board which is currently under review. Similarly, H3D was used to assess the fate of accidental fuel spills arising from a proposed jet fuel terminal in the Fraser River. This modelling work is part of the information package submitted to the provincial Environmental Assessment Office.

2.0 THEORETICAL BASIS

H3D is a three-dimensional time-stepping numerical model which computes the three components of velocity (u,v,w) on a regular grid in three dimensions (x,y,z), as well as scalar fields such as temperature and contaminant concentrations. The model uses the Arakawa C-grid (Arakawa and Lamb, 1977) in space, and uses a two level semi-implicit scheme in the time domain. H3D bears many similarities to the well-known Princeton Ocean Model (POM) (Blumberg and Mellor, 1987) in terms of the equations it solves, but differs in how the time-domain aspects are implemented. H3D uses a semi-implicit scheme, allowing relatively large time steps, and does not separately solve the internal and external models as POM does. It also uses a considerably simpler turbulence scheme in the vertical. These considerations combined allow H3D to execute complex problems relatively quickly.

The equations to be solved are:

Mass Conservation:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \quad (\text{A1})$$

At the end of each timestep equation, (A1) is used to diagnostically determine the vertical component of velocity (w) once the two horizontal components of velocity (u and v) have been calculated by the model.

X-directed momentum:

$$\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} + g \frac{\partial \eta}{\partial x} + \frac{1}{\rho_o} \frac{\partial}{\partial x} \int_z^\eta (\rho_w - \rho_o) g dz - f v \frac{\partial}{\partial x} A_H \frac{\partial u}{\partial x} - \frac{\partial}{\partial y} A_H \frac{\partial u}{\partial y} - \frac{\partial}{\partial z} A_V \frac{\partial u}{\partial z} = 0. \quad (\text{A2})$$

Y-directed momentum:

$$\frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} + g \frac{\partial \eta}{\partial y} + \frac{1}{\rho_o} \frac{\partial}{\partial y} \int_z^\eta (\rho_w - \rho_o) g dz + f u \frac{\partial}{\partial x} A_H \frac{\partial v}{\partial x} - \frac{\partial}{\partial y} A_H \frac{\partial v}{\partial y} - \frac{\partial}{\partial z} A_V \frac{\partial v}{\partial z} = 0. \quad (\text{A3})$$

Water surface elevation determined from the vertically-integrated continuity equation:

$$\frac{\partial \eta}{\partial t} = - \frac{\partial}{\partial x} \int_{-H}^\eta u dz - \frac{\partial}{\partial y} \int_{-H}^\eta v dz. \quad (\text{A4})$$

The effect of wind forcing introduced by means of the surface wind-stress boundary condition:

$$\left(A_V \frac{\partial u}{\partial z}, A_V \frac{\partial v}{\partial z} \right)_{z=\eta} = \frac{\rho_a}{\rho_w} C_{D,air} \bar{U}_{wind} \left| \bar{U}_{wind} \right|. \quad (\text{A5})$$

The effect of bottom friction introduced by the bottom boundary condition:

$$\left(A_V \frac{\partial u}{\partial z}, A_V \frac{\partial v}{\partial z} \right)_{z=-H} = K_{bottom} \bar{U}_{bottom} \left| \bar{U}_{bottom} \right|. \quad (\text{A6})$$

The bottom friction coefficient is usually understood to apply to currents at an elevation of one metre above the bottom. The bottom-most vector in H3D will, in general, be at a different elevation, i.e., at the midpoint of the lowest computational cell. H3D uses the 'law of the wall' to estimate the flow velocity at one metre above the bottom from the modelled near-bottom velocity.

The evolution of scalars, such as salinity, temperature, or suspended sediment, is given by the scalar transport/diffusion equation:

$$\frac{\partial S}{\partial t} + u \frac{\partial S}{\partial x} + v \frac{\partial S}{\partial y} + w \frac{\partial S}{\partial z} - \frac{\partial}{\partial x} N_H \frac{\partial S}{\partial x} - \frac{\partial}{\partial y} N_H \frac{\partial S}{\partial y} - \frac{\partial}{\partial z} N_V \frac{\partial S}{\partial z} = Q. \quad (\text{A7})$$

In the above equations:

$u(x,y,z,t)$: component of velocity in the x direction;

$v(x,y,z,t)$: component of velocity in the y direction;

$w(x,y,z,t)$: component of velocity in the z direction;

$S(x,y,z,t)$: scalar concentration;

$Q(x,y,z,t)$: source term for each scalar species

f : Coriolis parameter, determined by the earth's rotation and the local latitude;

$A_H(\partial u / \partial x, \partial u / \partial y, \partial v / \partial x, \partial v / \partial y)$: horizontal eddy viscosity;

$A_V(\partial u / \partial z, \partial v / \partial z, \partial \rho_{water} / \partial z)$: vertical eddy viscosity;

N_H : horizontal eddy diffusivity;

$N_V(\partial u / \partial z, \partial v / \partial z, \partial \rho_{water} / \partial z)$: vertical eddy diffusivity;

$C_{D,air}$: drag coefficient at the air-water interface;

$C_{D,bottom}$: drag coefficient at the water/sea bottom interface;

ρ_a : density of air;

$\rho_w(x,y,z,t)$: density of water;

ρ_o : reference density of water;

$\eta(x,y,t)$: water surface elevation;

$H(x,y)$: local depth of water.

The above equations are formally integrated over the small volumes defined by the computational grid, and a set of algebraic equations results, for which an appropriate time-stepping methodology must be found. Backhaus (1983, 1985) presents such a procedure, referred to as a semi-implicit method. The spatially-discretized version of the continuity equation is written as:

$$\eta^{(1)} = \eta^{(0)} - \alpha \frac{\Delta t}{\Delta l} (\delta_x U^{(1)} + \delta_y V^{(1)}) - (1 - \alpha) \frac{\Delta t}{\Delta l} (\delta_x U^{(0)} + \delta_y V^{(0)}) \quad (A8)$$

where superscript (0) and (1) refer to the present and the advanced time, δ_x and δ_y are spatial differencing operators, and U and V are vertically integrated velocities. The factor α represents an implicit weighting, which must be greater than 0.5 for numerical stability. $U^{(0)}$ and $V^{(0)}$ are known at the start of each computational cycle. $U^{(1)}$, and similarly $V^{(1)}$, can be expressed as:

$$U^{(1)} = U^{(0)} - g\alpha\Delta t\eta_x^{(1)} - g(1-\alpha)\Delta t\eta_x^{(0)} + \Delta tX^{(0)} \quad (A9)$$

where $X^{(0)}$ symbolically represents all other terms in the equation of motion for the u - or v -component, which are evaluated at time level (0): Coriolis force, internal pressure gradients, non-linear terms, and top and bottom stresses. When these expressions are substituted into the continuity equation (A4), after some further manipulations, there results an elliptic equation for $\delta_{i,k}$, the change in water level over one timestep at grid cell i,k (respectively the y and x directions):

$$\delta_{i,k} - (ce\delta_{i,k+1} + cw\delta_{i,k-1} + cn\delta_{i-1,k} + cs\delta_{i+1,k}) = Z_{i,k} \quad (\text{A10})$$

where ce , cw , cn , and cs are coefficients depending on local depths and the weighting factor (α), and $Z_{i,k}$ represents the sum of the divergence formed from velocities at time level (0) plus a weighted sum of adjacent water levels at time level (0).

Once equation (A10) is solved for $\delta_{i,k}$, the water level can be updated:

$$\eta_{i,k}^{(1)} = \eta_{i,k}^{(0)} + \delta_{i,k} \quad (\text{A11})$$

and equation (A9) can be completed.

At the end of each timestep, volume conservation is used to diagnostically compute the vertical velocity $w(j,i,k)$ from the two horizontal components u and v .

2.1 Vertical Grid Geometry

In the vertical, the levels near the surface are typically closely spaced to assist with resolving near-surface dynamics. In addition, the model is capable of dealing with relatively large excursions in overall water level as the water level rises and falls in response to varying inflows and outflows, by allowing the number of near-surface layers to change as the water level varies. That is, as water levels rise in a particular cell, successive layers above the original layer are turned on and become part of the computational mesh. Similarly, as water levels fall, layers are turned off. This procedure has proven to be quite robust, and allows for any reasonable vertical resolution in near-surface waters. When modelling thin river plumes in areas of large tidal range, the variable number of layers approach allows for much better control over vertical resolution than does the σ -coordinate method.

In addition to tides, the model is able to capture the important response, in terms of enhanced currents and vertical mixing, to wind-driven events. This is achieved by applying wind stress to each surface grid point on each time step. Vertical mixing in the model then re-distributes this horizontal momentum throughout the water column. Similarly, heat flux through the water surface is re-distributed by turbulence and currents in temperature simulations.

2.2 Turbulence Closure

Turbulence modelling is important in determining the correct distribution of velocity and scalars in the model. The diffusion coefficients for momentum (A_H and A_V) and scalars (N_H and N_V) at each computational cell are dependent on the level of turbulence at that point. H3D uses a shear-dependent turbulence formulation in the horizontal, (Smagorinsky, 1963). The basic form is:

$$A_H = A_{H0} dx dy \sqrt{\left(\frac{du}{dx}\right)^2 + \left(\frac{dv}{dy}\right)^2 + \frac{1}{2}\left(\frac{\partial v}{\partial x} + \frac{\partial u}{\partial y}\right)^2} \quad (\text{A12})$$

The parameter A_{H0} is a dimensionless tuning variable, and experience has shown it to lie in the range of 0.25 to 0.45 for most water bodies such as rivers, lakes and estuaries.

A shear and stratification dependent formulation, the Level 2 model of Mellor and Yamada (1982), is used for the vertical eddy diffusivity. The basic theory for the vertical viscosity formulation is taken from an early paper, Mellor and Durbin (1975). The evaluation of length scale is based on a methodology presented in Mellor and Yamada (1982).

For scalars, both horizontal and vertical eddy diffusivity are taken to be similar to their eddy viscosity counterparts, but scaled by a fixed ratio from the eddy viscosity values. Different ratios are used for the horizontal and vertical diffusivities. If data is available for calibration, these ratios can be adjusted based on comparisons between modelled and observed data. Otherwise, standard values based on experience with similar previously modelled water bodies are used. In a recent reservoir simulation, the ratio of vertical eddy diffusivity to vertical eddy viscosity was 0.75 and the ratio between horizontal eddy diffusivity and horizontal eddy viscosity was 1.0.

2.3 Scalar Transport

The scalar transport equation implements a form of the flux-corrected algorithm (Zalesak, 1979), in which all fluxes through the sides of each computational cell are first calculated using a second-order method. Although generally more accurate than a first order method, second order flux calculations can sometimes lead to unwanted high frequency oscillations in the numerical solution. To determine if such a situation is developing, the model examines each cell to see if the computed second order flux would cause a local minimum or maximum to develop. If so, then all fluxes into or out of that cell are replaced by first order fluxes, and the calculation is completed. As noted, the method is not a strict implementation of the Zalesak method, but is much faster and achieves very good performance with respect to propagation of a Gaussian distribution through a computational mesh. It does not propagate box-car distributions as well as the full Zalesak method, but achieves realistic simulations of the advection of scalars in lakes, rivers and estuaries, which is the goal of the model. This scheme as implemented is thus a good tradeoff between precision and execution time, important since in many situations, where more than one scalar is involved, the transport-diffusion algorithm can take up more than half the execution time.

2.4 Heat Flux at the Air-Water Interface

The contribution of heat flux to the evolution of the water temperature field can be schematized as:

$$\frac{dT}{dt} = \frac{\Delta Q}{\rho * c_p * h}$$

where ΔQ is the net heat flux per unit area retained in a particular layer, ρ is the density of water, c_p is the heat capacity of water and h is the layer thickness.

Heat flux at the air-water interface incorporates the following terms:

Q_{in} : incident short wave radiation. Generally, this is not known from direct observations. Generally, it is estimated from the cloud cover and opacity observations at nearby stations, a theoretical calculation of radiation at the top of the atmosphere based on the geometry of the earth/sun system, and an empirical adjustment based on radiation measurements at Vancouver Airport and UBC respectively for the period 1974-1977. This procedure has worked well for many water bodies, notably Okanagan Lake and the waters of

the north coast of British Columbia, in terms of allowing H3D to reproduce the observed temperature distributions in space and time. Values for albedo as a function of solar height are taken from Kondratyev (1972).

Q_{back} : net long wave radiation, calculated according to Gill (1982), involving the usual fourth power dependence on temperature, a factor of 0.985 to allow for the non-black body behaviour of the ocean, a factor depending on vapor pressure to allow for losses due to back radiation from moisture in the air, and a factor representing backscatter from clouds.

Q_L and Q_H : latent and sensible heat flux. Latent heat flux (Q_L) is the heat carried away by the process of evaporation of water. Sensible heat flux (Q_S) is driven by the air-water temperature difference and is similar to conduction, but assisted by turbulence in the air. Latent and sensible heat flux is described by:

$$Q_L = 1.32e^{-3} * L * windspeed * (q_{obs} - q_{sat}) * latent_factor$$

$$Q_S = 1.46e^{-3} * \rho_{air} * c_p * windspeed * (T_{air} - T_{water}) * sensible_factor$$

Where q_{obs} and q_{sat} are the observed and saturated specific humidities, T_{air} and T_{water} are the air and water temperatures, L is the latent heat of evaporation of water, and c_p is the heat capacity of water. ' $latent_factor$ ' and ' $sensible_factor$ ' are scaling factors introduced to account for local factors, and can be adjusted, when needed, to achieve better calibration of the model. Typically, the only adjustment is that $Sensible_factor$ is doubled when the air temperature is less than the water or ice surface temperature to account for increased turbulence in an unstable air column.

Light absorption in the water column. As light passes through the water column it is absorbed and the absorbed energy is a component of the energy balance that drives water temperature. H3D assumes that light attenuation follows an exponential decay law:

$$E(z) = E(z_0) * e^{-k*(z-z_0)}$$

The model computes the energy at the top and bottom of each layer and the difference is applied to the general heat equation in that layer. The extinction coefficient (k) is related to the Secchi depth (D_s) by

$$k = \frac{2.1}{D_s}$$

Temperature is treated like any other scalar as far as advection and diffusion are concerned. Heat flux at the water-sediment interface is not currently included in H3D.

2.5 Ice

The ice model is generally based on processes described in Patterson and Hamblin (1988). The ice cover is characterized by a thickness, a fraction of the cell covered, and an ice surface temperature. The temperature of the bottom of the ice is assumed to be the temperature of melting, usually 0° C. The strategy is to compute the differences in heat flux at the top and bottom of the ice layer and use this difference to determine the growth or decay rate and the change in temperature of the ice. The heat flux at

the bottom of the ice layer is dependent on lake temperature and water velocity. The heat flux at the top is dependent on meteorological processes and the surface temperature of the ice. The surface heat flux to the top of the ice sheet is calculated in a similar way as for open water, except that latent heat flux term (Q_L) also includes the heat of fusion. Albedo is also altered to account for ice/snow cover.

In order to start ice formation, once the surface water temperature drops below 3° C in a particular cell, a test ice layer of thickness 1 cm is initialized. If the test thickness melts in one time step, then the system cannot support ice cover in that cell at that time. If it survives, then the amount of ice in that cell is converted to a 1 cm thick region with coverage calculated from the mass of ice formed. In this way, a relatively robust start is made to ice formation.

The frictional interaction between the bottom of the ice and the immediately adjacent water is parameterized according to Nezhikhovskiy (1964).

2.6 Validation

Three validations of H3D's water level and temperature prediction skill are discussed below.

2.6.1 Strait of Georgia/Point Atkinson Tide: Wave Propagation

A fundamental concern with a circulation model such as H3D is how well it propagates waves, the carriers of information through the system. Figure A-1 presents results of a simulation of tides in the Strait of Georgia and Juan de Fuca Strait, with tidal elevations prescribed at the entrance to Juan de Fuca Strait and at a section north of Texada Island in the Strait of Georgia. The complex dynamics of the northern passes, such as Discovery Passage and Seymour Narrows, are thus avoided, allowing a test of H3D's wave propagation capabilities. The figure plots the modelled water level at Point Atkinson in red, and the observed water level in black. There is nearly perfect agreement, with the slight difference resulting from small storm surge events. This validation demonstrates that the selection of grid schematization (Arakawa C-grid) and the semi-implicit time-stepping approach have produced a system that can accurately propagate information through a water body.

2.6.2 Okanagan Lake Temperature Profiles

Obtaining good reproduction of the seasonally-evolving temperate structure of a lake indicates that the heat flux across the air-water interface is accurately parameterized and that the transport-diffusive processes operating in the water column are also accurately reproduced by the model. Figure A-2 presents a comparison of observed and computed temperature profiles at the northern end of Okanagan Lake near Vernon, in April, August, October and December of 1997. The agreement is very good as the model reproduced the transition from a well-mixed condition in the spring to the development of a strong thermocline in the summer, the deepening of the upper layer during the fall cooling period, and a return to isothermal conditions in winter. There is little doubt that H3D can compute accurate temperature distributions in water bodies, as long as adequate meteorological data is available. For this simulation, the meteorological data was obtained from Penticton Airport: winds, rotated to follow the thalweg of the valley; cloud cover, air temperature and relative humidity.

2.6.3 Thermistor Response: Okanagan Lake

Okanagan Lake is subject to significant fluctuations in the vertical thermal structure during the summer stratified period. Figure A-3 shows a temperature time-series at a site on the north side of the William R. Bennett Bridge which exhibits significant temperature excursions at periods of about 60 hours, or 2.5 days. Figure A-4 shows the modelled time series of temperature at three selected depths, 51 m, 21 m and 9 m. The occurrence and magnitude of the temperature fluctuations is generally predicted by the model, but the reproduction is not perfect: the occurrence and timing of the temperature events is quite good, but the modelled peaks appear to be generally somewhat broader in time. It was found that there were considerable differences in the simulated behaviour depending on whether winds at Kelowna Airport, which is situated in a side-valley, were included in the model or not. It is also clear that H3D can generally reproduce internal seiches in a lake, as long as adequate spatial resolution is used. This is particularly apparent when the coherent internal waves that propagate up and down the lake are examined in a longitudinal section, illustrated in two snapshots from a model simulation of such an event in Figure A-5.

This report incorporates and is subject to these “General Conditions”.

1.0 USE OF REPORTS AND OWNERSHIP

This report pertains to a specific site, a specific development, and a specific scope of work. The report may include plans, drawings, profiles and other supporting documents that collectively constitute the report (the “Report”).

The Report is intended for the sole use of Tetra Tech EBA’s Client (the “Client”) as specifically identified in the Tetra Tech EBA Services Agreement or other Contract entered into with the Client (either of which is termed the “Services Agreement” herein). Tetra Tech EBA does not accept any responsibility for the accuracy of any of the data, analyses, recommendations or other contents of the Report when it is used or relied upon by any party other than the Client, unless authorized in writing by Tetra Tech EBA.

Any unauthorized use of the Report is at the sole risk of the user. Tetra Tech EBA accepts no responsibility whatsoever for any loss or damage where such loss or damage is alleged to be or, is in fact, caused by the unauthorized use of the Report.

Where Tetra Tech EBA has expressly authorized the use of the Report by a third party (an “Authorized Party”), consideration for such authorization is the Authorized Party’s acceptance of these General Conditions as well as any limitations on liability contained in the Services Agreement with the Client (all of which is collectively termed the “Limitations on Liability”). The Authorized Party should carefully review both these General Conditions and the Services Agreement prior to making any use of the Report. Any use made of the Report by an Authorized Party constitutes the Authorized Party’s express acceptance of, and agreement to, the Limitations on Liability.

The Report and any other form or type of data or documents generated by Tetra Tech EBA during the performance of the work are Tetra Tech EBA’s professional work product and shall remain the copyright property of Tetra Tech EBA.

The Report is subject to copyright and shall not be reproduced either wholly or in part without the prior, written permission of Tetra Tech EBA. Additional copies of the Report, if required, may be obtained upon request.

2.0 ALTERNATIVE REPORT FORMAT

Where Tetra Tech EBA submits both electronic file and hard copy versions of the Report or any drawings or other project-related documents and deliverables (collectively termed Tetra Tech EBA’s “Instruments of Professional Service”), only the signed and/or sealed versions shall be considered final. The original signed and/or sealed version archived by Tetra Tech EBA shall be deemed to be the original. Tetra Tech EBA will archive the original signed and/or sealed version for a maximum period of 10 years.

Both electronic file and hard copy versions of Tetra Tech EBA’s Instruments of Professional Service shall not, under any circumstances, be altered by any party except Tetra Tech EBA. Tetra Tech EBA’s Instruments of Professional Service will be used only and exactly as submitted by Tetra Tech EBA.

Electronic files submitted by Tetra Tech EBA have been prepared and submitted using specific software and hardware systems. Tetra Tech EBA makes no representation about the compatibility of these files with the Client’s current or future software and hardware systems.

3.0 STANDARD OF CARE

Services performed by Tetra Tech EBA for the Report have been conducted in accordance with the Services Agreement, in a manner consistent with the level of skill ordinarily exercised by members of the profession currently practicing under similar conditions in the jurisdiction in which the services are provided. Professional judgment has been applied in developing the conclusions and/or recommendations provided in this Report. No warranty or guarantee, express or implied, is made concerning the test results, comments, recommendations, or any other portion of the Report.

If any error or omission is detected by the Client or an Authorized Party, the error or omission must be immediately brought to the attention of Tetra Tech EBA.

4.0 ENVIRONMENTAL AND REGULATORY ISSUES

Unless expressly agreed to in the Services Agreement, Tetra Tech EBA was not retained to investigate, address or consider, and has not investigated, addressed or considered any environmental or regulatory issues associated with the project.

5.0 DISCLOSURE OF INFORMATION BY CLIENT

The Client acknowledges that it has fully cooperated with Tetra Tech EBA with respect to the provision of all available information on the past, present, and proposed conditions on the site, including historical information respecting the use of the site. The Client further acknowledges that in order for Tetra Tech EBA to properly provide the services contracted for in the Services Agreement, Tetra Tech EBA has relied upon the Client with respect to both the full disclosure and accuracy of any such information.

6.0 INFORMATION PROVIDED TO TETRA TECH EBA BY OTHERS

During the performance of the work and the preparation of this Report, Tetra Tech EBA may have relied on information provided by persons other than the Client.

While Tetra Tech EBA endeavours to verify the accuracy of such information, Tetra Tech EBA accepts no responsibility for the accuracy or the reliability of such information even where inaccurate or unreliable information impacts any recommendations, design or other deliverables and causes the Client or an Authorized Party loss or damage.

7.0 GENERAL LIMITATIONS OF REPORT

This Report is based solely on the conditions present and the data available to Tetra Tech EBA at the time the Report was prepared.

The Client, and any Authorized Party, acknowledges that the Report is based on limited data and that the conclusions, opinions, and recommendations contained in the Report are the result of the application of professional judgment to such limited data.

The Report is not applicable to any other sites, nor should it be relied upon for types of development other than those to which it refers. Any variation from the site conditions present at or the development proposed as of the date of the Report requires a supplementary investigation and assessment.

It is incumbent upon the Client and any Authorized Party, to be knowledgeable of the level of risk that has been incorporated into the project design, in consideration of the level of the hydrotechnical information that was reasonably acquired to facilitate completion of the design.

The Client acknowledges that Tetra Tech EBA is neither qualified to, nor is it making, any recommendations with respect to the purchase, sale, investment or development of the property, the decisions on which are the sole responsibility of the Client.

8.0 JOB SITE SAFETY

Tetra Tech EBA is only responsible for the activities of its employees on the job site and was not and will not be responsible for the supervision of any other persons whatsoever. The presence of Tetra Tech EBA personnel on site shall not be construed in any way to relieve the Client or any other persons on site from their responsibility for job site safety.
